IN medical literature the post-war scene (as we hopefully call it) has been dominated by the multiple-author textbook and the conference report This multiplication of opinion between the same covers reflects progress in the application of several disciplines and habits of mind to a single group of problems, rather than an escape from monolithic authority into a confusion of experimental facts, and as such it is to be welcomed, even though it may make for bitty reading The kidney has been well served by such publications, including in this country the Ciba symposium in 1953,[1] the Cushny memorial lectures,[2] and the issue of the *British Medical Bulletin* on renal physiology and pathology[3] An important series of "seminars" on renal physiology appeared in the *American Journal of Medicine* in 1950, and now, following the changing fashion in nomenclature, we have in the same journal a "symposium on renal function"[4]—though it may be doubted whether the first series of papers was delivered to small discussion groups, or the second at a drinking-party The renal outsider may perhaps wonder what new thing can be said on this theme, but he has only to look into this most recent symposium to discover, with the active nephrophile,[5] that these are exciting times in which our knowledge of that marvellous organ, the kidney, is being added to in many ways

In their preface, G H MUDGE and J V TAGGART, the editors, draw attention to four "areas" in which "considerable progress is apparent" These are "the morphology and cellular fine structure of the nephron, concepts in the clinical appraisal of renal disorders, descriptive electrolyte physiology, and the cellular mechanisms which operate in renal tubular transport" Each of these "areas" seems to us perhaps to represent part of a larger whole, which might be summarised as a shift of emphasis towards tubular function and away from glomerular function and renal plasma-flow It is scarcely possible to overestimate the contribution made to renal physiology and pathology by the clearance techniques of HOMER SMITH, but there was a period about a decade ago when a superficial observer might have thought that the kidneys were of importance mainly in excreting substances such as inulin and *p*-aminohippurate (P A H), which they never normally encounter, rather than in regulating the output of physiological constituents of the urine To be sure, the limits of action of change in glomerular filtration-rate (G F R) on urine formation had to be defined, and it cannot be denied even now that fall in G F R is a major factor both in "extrarenal uræmia" and in some types of generalised œdema, but the attempt to make changes in G F R responsible for any alteration in salt balance has failed This failure is currently recognised in the term "glomerular-tubular imbalance", which is perhaps best regarded as an unhappy symbol of a transition period in applied renal physiology Progress is now coming from the application of new techniques and new thinking to the very varied functions of the renal tubule As examples of this we may mention the detailed study of the processes by which the urine is made acid, stemming from the work of PITTS and his colleagues[6], the application of DENT's technique of paper chromatography to define the "clinical patterns of tubular dysfunction", now reviewed by MUDGE[7], the use of histochemistry[8] and of nephron dissection[9] in localising functional and structural lesions of the tubule, and of course the description of the effects of aldosterone and other hormones on the tubular handling of electrolytes

New approaches to tubule function are well represented in the latest symposium PITTS[10] reviews the information on the site of action of various diuretics which is being obtained in his department by the "stop-flow" method—an ingenious technique in which the urine flow in dogs is arrested for a few minutes, after which continuous frequent samples are taken from the ureter At high rates of urine flow, stimulated by mannitol, successive samples of urine differ in composition in a way suggesting that they represent the fluid in successive segments of the nephron up to and including Bowman's space Analysis of twenty to thirty such samples in each experiment gives results consistent with a distal-tubule site of action of acetazolamide, but with a predominantly proximal-tubule action of the mercurial diuretic chlormerodrin MILNE and his colleagues[11] describe how differential permeability of membranes leads to a concentration of weak bases in acidic fluids and of weak acids in alkaline fluids, this concept is important not only in relation to ammonium excretion but also in the pharmacology of important agents such as salicylate, mecamylamine, and pempidine[12] Dilution and concentration of the urine, so often taken for granted or used as an empirical test of renal failure, are now reviewed in worthy detail by BERLINER et al,[13] who propose a modification of the ingenious but somewhat neglected "counter-current" physical mechanism of WIRZ[14] Some new thinking is certainly needed here to account for such apparent anomalies as the failure of water diuresis in hypopituitarism,[15] the inability of healthy people to form a concentrated urine for some days after a period of water-loading,[16] and the formation of a concentrated urine in the absence of antidiuretic hormone when G F R is reduced [17] TAGGART [18] reviews progress in the very difficult problem of active tubular transport Much of this progress has been negative, in the elimination of " mechanisms proposed in the past on rather superficial grounds ", but his account of glucose reabsorption and of P A H secretion indicates at least the way in which the application of metabolic energy to active transport is likely to be elucidated

In addition to the emphasis on tubular function, the papers in this symposium illustrate another way in which renal physiology is drifting away from the dominance of clearance techniques The first two papers, on electron microscopy [19] and on renal biopsy,[20] reflect the renewed interest in structure as a necessary basis for function These two papers are a partial fulfilment of some of the hopes expressed by JEAN OLIVER in his contribution to the 1950 series, entitled " an essay toward a dynamic morphology of the mammalian nephron " [21] Perhaps fortuitously, another paper in the present series, by BRADLEY and WHEELER,[22] stresses the differences between nephrons, in contrast to their statistical unity which is the unstated assumption of the clearance approach—an assumption which was pilloried by OLIVER in the trenchant query "When is a kidney not a kidney?" [23] So far from being uniform, the nephrons are apparently " notably multifarious, in dimensions, mass, configuration, construction and arrangement ", the evidence of a functional counterpart to these obvious variations in structure is still indirect, but it is increasing in cogency, even for the normal kidney

Looking at the symposium in general, it is apparent that the questions are still well ahead of the answers, but at least they are different questions, and perhaps in the long run more easily answered Most of the advances reported have been in physiology, and have not yet been digested into practical clinical use, but the work on diuretics,[10] on renal biopsy,[20] and on the kidney in potassium depletion [24] is already at this stage Most of the territory, in which we have planted a few signposts, lies between the desert and the sown, and it is not yet certain whether some of the concepts expressed will turn out to be words (" the daughters of earth ") or things—" the sons of Heaven " in the round Johnsonian phrase

The Right Background

THE part that physical environment plays in the treatment of physical illness has long been appreciated fresh air, sunshine, particular kinds of food, and exercise —all are recognised as often therapeutic Today we are beginning to appreciate the equal importance of mental environment in the treatment of mental illness, and this rediscovery is helping to change the atmosphere of mental hospitals In the past, as Dr DUNCAN MACMILLAN pointed out last week,[1] the environment of these places has too often not even been neutral it has been actively unhelpful Certification, deprivation of civil rights, segregation from the rest of the community, and confinement behind locked doors are procedures which, however well intentioned, can only increase the tension, uncertainty, and bewilderment of the patient and aggravate the disturbance of his mind and feelings

But environment can do more than fail to hinder recovery It can actively speed the patient's progress, and today the hospital environment is no longer regarded as a mere custodial background—against which active therapy flamed and then too often faded—but as part of the patient's treatment The clearer this becomes, the more important it is that he should be placed in the most suitable environment, and this in turn demands a subtler classification of patients according to their needs and a greater diversity of hospital accommodation Unlike many reforms, this may prove an economy as well as an advance Professor MCKEOWN and his colleagues [2] in their survey of 3555 residents in Birmingham mental hospitals found that only 13% needed the full range of hospital facilities, 75% needed only limited hospital services, and 12% needed none of the traditional ones MCKEOWN thinks that in the hospitals of the future these three different kinds of patients should be in separate units

Ways in which the hospital unit can be varied according to the patient's need have also been discussed by Dr MINSKI, drawing on his experience as physician and superintendent of a neurosis centre from 1938 to 1957 [3] In his view the ideal administrative framework for the care of mental patients would comprise a neurosis hospital, an acute psychiatric hospital, and a hospital for long-stay patients—all under the same management committee, and with the same senior doctors working in all three In this way the task of looking after the chronic cases would be shared between the medical staff He suggested that registrars coming fresh from general medicine should begin their psychiatry in the neurosis centre, where they would find patients of a kind already familiar to them He would like to see some beds in general hospitals reserved for neurotic and psychosomatic cases so that medical and nursing staff should have more experience of looking after these patients Observation wards should also, in his view, be attached to general rather than mental hospitals, for many of the patients admitted to these beds would then never need to go to a mental hospital But if in this way the general hospital could usefully take part in the care of the mental patient it should in return have help in its outpatient department To give the necessary continuity of care, a psychiatrist from the complementary mental hospital should be on the staff of the outpatient department of the general hospital

Dr MINSKI has described his ideal, albeit an ideal formed by experience Dr BAKER on p 253 describes a reality in which progress, if not perfection, is being achieved by improvisation Like Professor MCKEOWN and Dr MINSKI, he asks for the division of our huge monolithic mental hospitals into smaller, livelier, friendlier units, and he describes how, at Banstead Hospital, a modest start has already been made A non-statutory unit and a tuberculous unit have already been opened, and in defiance of structural difficulties the 1200-bed institution is to be divided up and transformed, if all goes well, into three admission hospitals, a geriatric hospital, a hostel, and a reablement unit Dr BAKER believes that if we made better use of our hospital beds we should not need so many of them The Banstead experiment in functional division is a brave effort to free psychiatric practice from the domination of what he justly describes as our "huge over-populated unwieldy mental hospitals"

Annotations

TREATMENT OF THE PSYCHOPATH

SOME of the most obstinate problems in psychiatry revolve round the clinical condition known as "psychopathic personality" The very concept is so hard to delimit and so open to argument that the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency, while advocating wide compulsory powers, left the definition open[1] But the diagnosis is child's play compared with the difficulties of management, and the remarks on treatment by Dr Melitta Schmideberg, chairman of the Association for the Psychiatric Treatment of Offenders, in a lecture to the Institute for the Study and Treatment of Delinquency on July 23 were of great interest

Drawing on her experience in Europe and the United States, Dr Schmideberg pointed out that the usual criterion of psychopathy was antisocial behaviour, but this did not necessarily involve breaking the law The narcissistic element was pronounced, and this love of self with slight regard for others led to a peculiar idea of reality in which the future consequences of present actions could not be judged the capacity to learn from experience was similarly one-sided, and, while the psychopath's errors seemed to make him more adept in criminality, punishment was not often deterrent Ideas of grandeur and "magical" modes of thinking seemed to be involved in his usual belief that he could not be caught Although the whole life-pattern showed self-destructive tendencies, suicide among psychopaths was rare the borderline between psychopathy and schizophrenia was sometimes vague and could be crossed in either direction There was always a strong wish for pleasure, and a need for immediate gratification, but the capacity for enjoyment was slight Although anxiety and guilt were said to be characteristically absent, Dr Schmideberg was sure that they existed but were denied indeed antisocial acts often arose as an expression of anxiety The sadistic element was clear enough in the various aggressive acts, and, as Dr Peter Scott pointed out in the discussion, masochistic traits in some cases made punishment worse than useless since this was just what the patient unconsciously sought

As to the origins of the condition, Dr Schmideberg, for a psychoanalyst, laid surprisingly little emphasis on trauma in early life Maternal deprivation was but one factor She pointed out that increasing numbers of psychopaths in America come from well-ordered middle-class homes, similarly there were deprived slum children in whom psychopathic traits did not develop The development of social ideals and self-control was what socialised, and it was in this area that the psychopath was most disturbed The prevalence of crime was greatest not in towns like New York and Chicago but in affluent areas such as California She felt that American ideals were becoming increasingly psychopathic, crime bred crime, and vivid newspaper reporting had much to answer for (It could be added to her list of external causes that tough police methods constitute a "challenge" to delinquents which may have much to do with the extreme violence of some American adolescent outbursts)

Dr Schmideberg believed that treatment out of prison was often preferable, since only in society could the patient face his relationship problems in the work and sexual sphere The difficulty was that the severe psychopath did not *want* to change his sole interest in doctors was in using them to get out of trouble For this reason interpretations of behaviour given during psychotherapy would probably be used by the patient as an excuse for further offences and a means of putting the blame for his behaviour on to others (e g, his parents) Analytic treatment must be employed with caution, and the defences against real insight were enormous Success could be hoped for in reluctant patients only when they were obliged under threat of punishment to receive treatment, thus probation and suspended sentences were, in Dr Schmideberg's view, invaluable Some doctors disliked the idea of their patients being "forced" to receive treatment from them, but it was the unwilling ones who required attention most urgently The art of the therapist consists in turning the enforced relationship into a genuine one, and it was mainly this genuine relationship that socialised the patient Under the suspended sentence, the sentence was postponed and finally pronounced after periodic appearances in court and reports from the therapist This and probation, she considered, were admirable devices, which provided just the right blending of authority with threat from the court and support from the therapist The initial relationship came most easily just before the trial, and she used challenging and directive methods related to real-life situations concerning the patient's actions and their consequences The process of producing motivation was half the problem, and, once the patient wished to change, the process became one of re-education One criterion of success was stability at work, for if a man was not in work he would steal Adjustment was always hard, because the psychopath expected disproportionate praise for anything he did Dr Schmideberg departed again from analytic practice in that she verified incidents and progress by means of information from the family, employer, and probation officer if it could be tactfully obtained without hurting the patient

Dr Maxwell Jones rightly indicated in the discussion that relationships in the work and sexual spheres could be built up in certain kinds of institution, and that commentary and prohibition might be more effective to the patient when derived from his peers instead of from authority Many will differ from Dr Schmideberg's views and methods, but their particular virtues seem to be their realism and common sense It is to people with her energy and positive approach that we look for new ideas and methods—the trouble is that methods already in use remain somewhat unknown quantities Apart from the work at Belmont,[2] Simpson has an interesting unit at Wormwood Scrubs,[3] and elsewhere different types of formal psychotherapy and psychoanalysis have been used Everyone working in or observing these endeavours must agree that "things happen" (treating psychopaths may be trying but it is certainly not uneventful), and the dynamic situations that arise are of much scientific interest But the ultimate results are hard to judge, and comparison of one kind of management with another is impossible

WHY PEOPLE SMOKE

TEMPERAMENTAL differences between smokers and non-smokers have been described by Heath[4], and now McArthur et al[5] have published further observations on the same group of men Their subjects were 252 Harvard graduates who, while at the university in 1938–42, were selected for a study of adult development because of their apparent normality They were examined by psychological and various other techniques, and their progress was checked by annual questionaries, tests, and visits Smoking habits were among the extensive data collected about these men, and information accumulated over a fifteen-year period was available for analysis

Believing with Bales[6] that the social and cultural environment is the most potent influence on habit formation, McArthur et al considered that non-smoking was likely to be commonest in the lower middle class of the U S A , since there is evidence[7 8] that people of this rank, more than those above or below them in the social scale, still cleave to values derived from what has been called the Protestant Ethic[9]—religious doctrine according to which it is sinful to waste time and substance on unprofitable activities Children reared in this tradition are taught to eschew frivolity, and to be upright, industrious, and ambitious[8 10 11] It seemed probable, therefore, that members of the middle class would be less likely to indulge in a pleasure of the flesh, such as smoking, than members of other less ascetic sections of the population In order to test this hypothesis they compared the smoking habits of men who had prepared for Harvard at public high schools with those of men who had prepared for Harvard at private preparatory schools, as the high-school graduates were mainly of middle-class and the preparatory-school graduates of upper-class origin They found, in fact, that there was a highly significant correlation between smoking and exclusiveness of school 20% of the graduates of very exclusive private schools, 30% of the graduates of less exclusive private schools, and 40% of the graduates of public schools did not smoke At first sight it might appear that a public-school education is less conducive to smoking than a private-school one, but this is not so, *for it has been estimated*[12] that only 9% of boys at American public schools do not smoke! It must therefore have been *from this select minority* that the Harvard public-school non-smokers were recruited They were predominantly earnest young men of the middle class, the pride of their families, heavily indoctrinated with "work morality", and bent on achieving the status of a technical or professional career The upper-class private-school boys, on the other hand, aimed rather at conformity with an accepted code of behaviour than at advancement through self-denial, and most of them went into business A significantly high proportion of non-smokers had pious parents, and the sons were often more pious than the fathers In short, it would appear from the findings of this investigation that a comparatively poor but very honest Protestant, keen to "improve himself", is more likely than most in America to remain a non-smoker, and McArthur et al quote a market survey carried out in England[13] which suggests that here also non-smoking is associated with "middle class respectability"

Whatever the reason for starting to smoke, it may be assumed that the degree of addiction will be determined by the extent to which the habit satisfies the personal needs of the smoker It is generally believed that smoking is indulged in to allay anxiety, but McArthur et al found no convincing evidence of a general tendency in their subjects to smoke more heavily in times of stress, *although they admit that their experiment was not ideally* designed to test this point However, as 70% of heavy smokers and only 30% of light smokers said they smoked more when under pressure, it seemed possible that smoking may become a suitable tension reducer only when it has become a deeply ingrained habit Heavy smoking in their study was found to be most significantly correlated with a "coartated" performance of a special Rorschach test—that is, a record indicative of a lack of emotional resources Coartated men were "inarticulate, pragmatic, and bland hard to get to know compulsive fiddlers, desk-arrangers, people who allayed their tension through fussy activities" Once a coartated person started to smoke he tended to smoke heavily, no matter what his social background had been Moreover, he tended to smoke increasingly, so that if he started late he was soon smoking more than men who had started early Among the heavy smokers who were not coartated there was, as Heath[4] has already observed, a significantly high proportion of impulsive men with poorly integrated personalities

As regards ability to stop smoking, the amount of tobacco previously consumed was found to be the most *significant factor* It was estimated that men who have smoked a mean number of 9 cigarettes a day can stop, men who have smoked 18 do not try, and men who have smoked 20 cannot (Presumably it is assumed that some 18-a-day men can stop if they try) The ability of the subjects of the study to stop smoking was also significantly related to the length of time they had been breast-fed Light smokers who could stop had been weaned at 8 months, heavy smokers who could stop had been weaned at 6 8 months, smokers, mostly heavy, who did not try to stop had been weaned at 5 months, and smokers, mostly heavy, who tried to stop but could not had been weaned at 4 7 months McArthur et al do not suggest that there is an immediate connection between early weaning and inability to stop smoking—the time of weaning may reflect only a certain pattern of infant training—but they point out that smoking is associated with a liking for other oral gratifications. smokers tend to drink more alcohol and coffee than non-smokers,[4] and if they stop smoking they are apt to substitute food for tobacco.[14] Also, a lower than average proportion of men who could stop smoking had been bottle-fed babies, and a higher than average proportion of men who could not were reported to have sucked their thumbs in childhood. McArthur et al. therefore conclude that, although the amount of tobacco previously consumed is of prime importance in determining whether or not a person can stop smoking, an "orality" factor may also be influential.

Perhaps the most interesting finding of this study is that in the past some parents, on general principles, have persuaded their children not to smoke. Now that the perils of cigarette smoking are so widely known, it would be even more interesting to learn what parents are managing to persuade their children to avoid the habit on the specific ground that it is dangerous to life.

ANTIBODY TO PENICILLIN

Ley *et al.*[15] have reported a new and interesting observation—that specific antibody to penicillin may be demonstrated in some human sera. The discovery was made accidentally. Penicillin was added as a routine to preserve red-cell suspensions used in a blood bank. The serum of one prospective recipient of a transfusion was found to agglutinate all red cells against which it was tested, but the agglutination did not appear when the same serum was tested against red cells which had not been mixed with penicillin. When the patient's red cells were treated with penicillin, they also were agglutinated by his own serum. Investigation showed that red cells of all human blood-groups could be made agglutinable to antibody-containing sera in this way, but so far only with the penicillins G, O, and K, and the penicillin derivative synnematin B. Results were negative in tests with streptomycin, dihydrostreptomycin, polymyxin B, bacitracin, neomycin B, ristocetin, viomycin, and oleandomycin, but it is not stated whether cells sensitised with these agents were put against sera likely to contain antibody to them or only against sera known to contain antibody to penicillin. Penicillin inactivated by penicillinase did not sensitise the red cells, but red cells once sensitised could not be desensitised by subsequent treatment with penicillinase, papain, or ficin. Sensitisation of red cells with penicillin proceeded in proportion to the concentration of the drug and time of exposure, reaching a maximum in about twenty-four hours and persisting for as long as the cells remained useful for testing—that is, for some two to three weeks.

To carry out tests for serum antibody, Ley et al. prepared penicillinised red cells by adding 8 ml. of a mixture of equal parts of whole blood and Alsever's solution to 200,000 units of powdered penicillin G. After incubation at 37°C for an hour the red cells were washed thrice in physiological saline solution and made up to a suitable suspension (4–10%) in physiological saline. The incubation temperature was not critical, since sensitisation could be accomplished at any point in the range 6–37°C. Antibody was eluted from sensitised cells by heating them at 54°C for fifteen minutes, the antibody was stable at refrigerator temperatures and resisted 56°C for two hours. Its possession of many of the known attributes of a true antibody, and its specificity, thus appear to be well established; further, it may be completely adsorbed from sera by their exposure to concentrations of penicillin of the order of 12,000 units per ml. or greater. A positive reaction between antibody-containing serum and sensitised red cells may be easily demonstrated by conventional slide or tube agglutination methods if there is enough antibody, and by anti-globulin methods if there is not. So far, Ley et al. have detected 25 positive sera among about 2000 tested. All who yielded positively reacting sera had received penicillin treatment at some time, but only a minority had been known on clinical grounds to be sensitive to penicillin.

This report is of great interest both because it offers a possible method of studying the sensitisation of patients to penicillin—an important problem in its own right—and because, despite the negative results with other antibiotics so far tested, this report raises the hope that the valuable method of red-cell agglutination may perhaps, with appropriate technique, be yet found adaptable to the study of other hypersensitivity phenomena, which cause so much distress to their victims and appear to be an increasing feature of medical practice.

EXPERIMENTAL MONILIASIS

MONILIASIS is attracting attention because overgrowth of the causal agent, *Candida* (formerly *Monilia*) *albicans*, is commonly observed in patients treated with antibiotics—particularly, it seems, with broad-spectrum antibiotics such as chloramphenicol and the tetracyclines. Usually this overgrowth is without clinical significance, but exceptions are common enough to maintain our interest in the influences that may favour or counteract invasion of tissue by *C. albicans*. Studies of these problems are reviewed by O'Grady and Thompson,[1] who describe their own experimental approach, which has novel and notable features.

To begin with, they chose to work with a lesion produced by inoculating *C. albicans* into the left thigh of mice. This was done to eliminate the uncontrollable and unmeasurable effects that might arise in experiments where a local bacterial flora was normally present. It is suspected that, in actual practice, monilial overgrowth may be due partly to suppression of normal flora, but the unresolved question which was studied was whether an antibiotic might have a more direct effect either on the growth of the candida or on the defences of the host. The closed lesion in the thigh of the mouse met this point. Furthermore, objective, accurate, rapid, and frequent measurements of the progress of the experimental infection could be made by measuring daily with sliding callipers the mediolateral diameters of the thighs and thence calculating the average increase compared with the normal thigh. O'Grady and Thompson examined Seligmann's[2] postulate that chlortetracycline (aureomycin) exerts on the response of the host to candida infection an effect analogous to that of cortisone. In the effects of cortisone and chlortetracycline they discovered, by their approach, two similarities and two differences. Both drugs caused a decrease in size of the experimental lesions, which was followed by a rapid increase when treatment was stopped. In addition, if the dose of chlortetracycline was high enough, the diameter of the thigh on the side

15. Ley, A B, Harris, J P, Brinkley, M., Liles, B, Jack, J A, Cahan, A. *ibid*, 1958, 127, 1118.

1. O Grady, F, Thompson, R E M *Brit J Pharmacol* 1958 13 1
2. Seligmann, E *Proc Soc exp Biol*, N Y 1952, 79, 481 1953, 83, 778

of the lesion continued to be above the control value, as with cortisone—a demonstration of the rebound effect, already well known with cortisone

Intramuscular injection of cortisone alone reduced the diameter of the thigh a little, and injection of cortisone along with candida reduced the candida lesion compared with untreated controls Chlortetracycline by itself, on the other hand, produced a large swelling, and if given along with candida produced a very large and persistent mass When the drugs were given subcutaneously to animals which received the candida separately, the suppression and rebound resulting from cortisone could not be reproduced by subcutaneously administered chlortetracycline in any dosage On the contrary, the reduction in size of the lesion from subcutaneously administered chlortetracycline became increasingly long-continued with increased dosage, but rebound was not observed even when the chlortetracycline was given for two days only From other experiments, which involved the use of many substances which might conceivably have imitated the main effects of cortisone and chlortetracycline, it became clear that the action of aspirin in this infection did not resemble that of cortisone or chlortetracycline and that chlortetracycline was not acting as a simple irritant, however important its irritant action undoubtedly was in enhancing the lesions when it was given along with *C albicans*

O'Grady and Thompson have certainly given us something interesting to ponder, even if neither they nor we can be quite certain of what it all means in terms of clinical medicine

ADOLESCENCE

THE consequences of human polymorphism in development-rate have lately been underlined once again by Tanner[1] By carrying out one of the first really large studies that included longitudinal as well as cross-sectional observations[2] Tanner has shown the extent of this polymorphism, which is seriously obscured if events at puberty are pictured from cross-sectional averages There is a large diversity in the patterns of change and the rates at which they occur over the period from 9 to 16 years of age by plotting the time of occurrence and range of onset of the spurts of fat deposition, height gain, genital development, and muscular strength, it can be seen that "an early-maturing boy may have finished his entire adolescence before a late-maturing boy of the same chronological age has even begun his first enlargement of the testis" This diversity—which is obvious from general experience once it has been pointed out, but for which astoundingly little allowance is made—has important educational implications Tanner also draws attention to the likelihood of psychological effects associated with late or early development in a given social setting The early developer may be precocious and popular (or alternatively precocious and embarrassed), the late may become despondent over his sexual or athletic inadequacies None of these will be constant effects—in different social settings they may operate to produce opposite results—but there seems little doubt that rate of development may be a more important determinant of personality than has generally been conceded Since, moreover, early or late puberty are likely, on animal evidence, to be heritable, possibly one should seek here the supposed "genetic" bases of various personality characters—homosexuality or excessive shyness, for example, which show twin and sib correlations

Tanner's work is a shining example of the realisation of human polymorphism—of the number of different "normalities"—which human biology is contributing to medicine The follow-up of these series into adult life will contribute still more It would be interesting to know, for example, whether rate of development and rate of senescence are positively linked, or negatively as in hybrid vigour, where hybrid animals both develop faster and live longer than inbred

THE RUSSIAN VACCINE

UNCERTAINTY about the Russian vaccine which has been used in the treatment of multiple sclerosis[1-3] is lessened by a letter in last week's *British Medical Journal* Writing from Moscow, Professor Shubladze and Professor Dick say that it is necessary to reinvestigate and characterise the original isolates of the SV strain of acute encephalomyelitis virus from which the vaccine of Shubladze and Margulis was prepared, because recent experiments have shown that the SV strain in current use is similar to rabies virus Further recommendation about treatment with the vaccine cannot, they add, be made until these new inquiries have been completed Dick and his colleagues in Belfast had earlier reported[4] results suggesting that the virus was rabies virus, and it is welcome news that Professor Shubladze and Professor Dick have been able, by personal discussion, to throw light on a confused situation

LIFE PEERS

THE traditions and institutions that survive longest are those that can assimilate and accept change with grace and realism, and for some time it has been apparent that the House of Lords was remaining dangerously unchanged in a changing world The reform now being undertaken is a further breach in the hereditary principle Already the Law Lords sit as life peers, and the Bishops only while they hold their sees, and now the number of life peerages is to be gradually raised, so that the House shall contain more members willing and able to devote a good deal of time to its business We are glad to note that the list of fourteen new life peers announced last week contains the names of two doctors

Sir John Stopford, as a past vice-chancellor of the University of Manchester, a fellow of the Royal Society, and an emeritus professor of experimental neurology, has the background of an administrator and a scientist Dr Stephen Taylor has already had some taste of politics as M P for Barnet from 1945 to 1950 Since then, to his war-time experience as the director of Home Intelligence and the War-time Social Survey, he has had added the knowledge of social medicine he has gathered from his special studies, on behalf of the Nuffield Provincial Hospitals Trust, of general practice and of the health service He is also director of the industrial health service of the new town of Harlow, in whose development he has played no small part

BREAKING UP THE MENTAL HOSPITAL

A. A. BAKER
M.D. Lond., D.P.M.
DEPUTY PHYSICIAN-SUPERINTENDENT, BANSTEAD HOSPITAL,
SUTTON, SURREY

THREE years ago, Banstead Hospital housed 2450 patients, and there was a waiting-list. There are now some 2000 patients in the hospital and no waiting-list. Yet, during these years the annual number of admissions has risen by 40%, and the hospital's catchment area has grown, adding some 40,000 people to the population which it covers.

REFORMS AND RESULTS

These changes are largely due to our interpretation of the new outlook on the duties and responsibilities of the mental hospital.

We have assumed that all patients entering hospital come for treatment and expect to return to their homes. Therefore, every admission, however apparently hopeless the prognosis, has had active treatment and rehabilitation, whether he was a new patient, a readmission, or a geriatric patient. The only exceptions have been patients with a progressive organic dementia.

All admissions have been treated in fairly small wards, all of them open, with maximum privileges.

Instead of admitting all disturbed women patients to one ward as in 1955, we now admit them to four wards. One ward is reserved for the physically ill, the allocation of patients to the other three wards is determined partly by age and partly by diagnosis.

We have been in touch with relatives, friends, and employers, and asked them to ensure that a place in the community is kept open for the patient.

Physical treatment, particularly E.C.T. and the tranquillisers, is used extensively, not only to alleviate symptoms, but also to enable the patient to make full use of the therapeutic social activities we offer him.

We have started many social and occupational activities, of which the small factory within the hospital itself was one.

The nursing staff have, of course, played a large part in the changes. Two maxims have been of the greatest importance. The nurses have been encouraged to treat the patients on the understanding that "their patient today may be their neighbour tomorrow". Secondly, it was made clear to them that when a long-stay patient was made fit to resume life outside hospital, his place in the overcrowded ward would not be taken by another. Thus the nurses knew that success in their efforts to help a patient would mean an improvement in conditions. The old policy by which vacancies on long-stay wards were filled with more disturbed patients from elsewhere discouraged the nurses.

In 1955, not only were the wards overcrowded, but they were too big. Among twenty-six wards on the women's side we had seven with over 100 beds in each. As a result of our discharges and some rearrangement, no ward now has more than 60 beds, though this is still twice as many as we should like.

Another result of our discharge policy has been the development of our outpatient service, for we had to provide supervision and further treatment for more patients. Our outpatient clinics have all expanded—some as much as sixfold in the last three years.

PLANS AND PROPOSALS

One of the biggest problems in our present mental hospitals is their size. During the Victorian era when they were built, the policy was to provide custodial care and to house as many patients as possible as cheaply and conveniently as possible. The large barnlike wards therefore accommodated at least 100 patients, and each of the large prison-like hospitals held 2000–3000. We have made some progress in reducing the number of patients in a ward, but the 2000-bed mental hospital is much too large, however small the individual wards become. It cannot possibly form a "social field", in Lewin's sense, in which each individual influences the whole, and the whole influences each individual. No doctor or nurse can possibly know all the patients, and each person in the hospital inevitably feels relatively insignificant. We should aim at hospitals of 200–300 beds. Since these hospitals cannot at present be built, we have started to try to break up our present colossus into smaller, more manageable units. For example, we have now a 100-bed non-statutory unit which was originally built as an admission ward, and also a 100-bed unit for tuberculous men which serves the South West Metropolitan region. But we are still left with the main mass of the hospital, which on the women's side means 1200 patients shared between twenty-five wards.

There seems no obvious way of breaking up our ward blocks structurally, but we propose to divide them functionally, so that each unit provides a complete hospital service of its own. These hospitals within a hospital will each be run by a doctor who will be responsible for treatment and transfers within the unit. Each will have its own "matron" and nurses and ancillary workers.

We plan to break up our 1200-bed unit into three admission hospitals, each with 200 beds, a geriatric hospital with 300 beds, a hostel for patients working in the hospital industries, with 250 beds, and rehabilitation unit with 50 beds.

The three admission hospitals would be the *geriatric* unit (with 1 admission ward, 1 convalescent ward, and 2 wards for patients whose physical health is deteriorating and whose discharge is unlikely), a unit for *young, disturbed patients* usually with schizophrenia (with 1 admission ward and 3 wards providing graduated social training and rehabilitation), a similar unit for *middle-aged patients* of roughly forty to sixty.

Part of the proposed geriatric hospital already houses the most frail or physically ill of our long-stay senile population. In view of the present demand for geriatric beds and our ageing long-stay population we propose to bring the number of beds up to 300 so as to provide an adequate geriatric service for the long-stay wards in the hospital.

As many of our patients, though employable and needing practically no supervision, have not been able to find a suitable niche in the community, we provide accommodation for them within the hospital and this unit will become the proposed hostel. From these wards the patients go out in the morning to work in our factory projects or to do hospital domestic work. They eat in the hospital's self-service cafeteria. They take part in the social opportunities of the hospital and of the local community.

The small rehabilitation unit will be used for the active rehabilitation of patients from the long-stay wards who are planning to leave hospital in the near future. It will enable them to concentrate on their social problems, and when they move into this ward we shall be able to see their capacity to adjust to a new situation. As we are extremely short of social workers, the nurses on this ward will probably perform some of their duties.

DISCUSSION

When an unwieldy hospital is broken into smaller units, group and community techniques become feasible, morale improves, and patients and staff develop a greater sense of purpose and a clearer idea of their function in the therapeutic community But to obtain the best results each doctor should be in charge of a unit for not less than a year and preferably longer Under our present system, where the units are formed by segregating patients according to age or length of stay, doctors tend to have a restricted experience of inpatient psychiatry The benefits of our proposals are most obvious to the junior nursing staff, but they will exact a considerable change in attitude and function among the senior nurses, who have usually been trained for a different system of organisation and who can feel, justifiably, that much of their training and experience is now set aside, while fresh demands are made upon them

So far as we have been able to progress with our scheme, there seems no doubt that the patients benefit by it They have continuity of treatment and human relationships Their problems are no longer "lost" by transfer from one therapeutic group to another Under our scheme all parts of the hospital will have positive functions instead of merely providing beds

It should be made clear that the provision of hostel accommodation and sheltered workshops is *not* the proper function of a mental hospital These facilities should be in the community, and, though they need some psychiatric supervision, they should be run by the local authority Though many of our patients using our hostel and workshop have made an excellent social adjustment, it is an adjustment within hospital and their prospects of discharge are now lessened rather than increased, for the community outside can offer no improvement in their way of life

We expect the number of patients in the hospital to continue to fall at the rate of 100 a year, but this reduction could be greatly speeded if the local authority provided adequate aftercare services A hospital of 300–500 beds would probably suffice for the treatment and hospital care of the patients we are at present admitting Unless we are aware of this possibility and encourage the changes in attitude, both in the hospital and in the community, which will be necessary to achieve it, huge overpopulated unwieldy mental hospitals will continue to dominate psychiatric practice and absorb an increasing proportion of the health services expenditure

THE BRITISH DIET

In 1956 in this country the transition to a free market was almost complete, and the National Food Survey Committee's report [1] for that year is their first to record household diets under trading conditions similar to those prevailing before the war

Comparing 1956 with 1934–39, the biggest change is an increase of 37% in milk consumption Meat consumption is up by 3%, but fish is down by 16% A decline of 37% in butter is almost completely offset by an increase in margarine Cereals are down by 8%, but potatoes are up by 16% Fruit and vegetables are almost unchanged The nutrients available from these supplies show few significant changes Daily intake of calcium per head has gone up by from 688 to 1107 mg per day, derived partly from the extra milk and partly from artificial addition to bread Total calories have increased from 3000 to 3140 per day, protein from 80 to 83 g per day, and fat from 130 to 138 g per day (These figures take no account of the distribution of the food or of the inevitable losses in the wholesale and retail trade)

In 1956 the National Food Survey recorded the diets consumed in 9617 households involving 31,063 persons

The households were chosen to give a statistically valid sample of different social classes and of different parts of the country Special attention was paid to the income of the householder and to the proportion of the income spent on food, but the surveys do not cover food eaten outside the home, in restaurants and canteens

In all economic classes the average daily intake of all the nutrients is satisfactory as judged by the B M A Nutrition Committee's recommendations Differences between the social classes still exist, but these are much smaller than in the pre-war years, when at least 10% of the population were not getting a sufficiency of essential nutrient The figures show that no large section of the community are underfed, judged by modern physiological standards But, as the data collected covered less than 1 in 1000 of the population they do not exclude the possibility that a minority numbered in tens of thousands may still not be getting a physiologically adequate diet

Households dependent on old-age pensions and those with four or more children are the most likely to be underfed

In 1956, 245 households dependent on pensions and with an average total weekly income of less than £6 10s were surveyed The average expenditure per person in these households was 27*s* 10*d* The average physiological value of the diets consumed was satisfactory and this indicates that the majority of old people were getting enough to eat

The number of families with four or more children surveyed was 236 Again the average intake of nutrients was satisfactory, but the numbers—especially in the lowest economic group—were small It is recorded that the average weekly expenditure on food by an adult couple increased between 1952 and 1956 from 57*s* 3*d* to 72*s* 9*d*, whereas the regression estimate of extra expenditure for each additional child rose from 8*s* 6*d* to 8*s* 10*d* a week in the same period From these figures it seems reasonable to conclude that solitary couples have been able to keep up their usual food customs despite the inflationary period, whereas large families must have had to make considerable economies Yet there is no evidence that these economies have reduced the intake of nutrients below physiological standards

A large section of the survey has been devoted to geographical differences in the household diets

These differences seem of little or no public-health importance, though no doubt they will be keenly studied by the market-research investigators and may even divert a general reader The Welsh spent more money on butter than anyone else but much less on eggs than the national average In Scotland they spent much more money on cakes and biscuits, but less on fresh green vegetables than the average Londoners appear to have spent most on vegetables, fruit, and milk, and, despite the higher prices, to have consumed more The Midlands top the list easily for expenditure on cheese The North and Yorkshire are right at the top in expenditure on flour, suet, and dripping, and this seems to be the region to go to for home-made cakes The long table recording these differences deserves study by any family contemplating a holiday in lodgings and undecided where to go But on turning to the table where everything has been reduced to calories, carbohydrates, vitamins and the rest, the local interest has disappeared and uniformity at a satisfactory level is presented

A detailed appendix sets out quantitatively the different foods which are the source of fat in households of different economic class, in different geographical regions, and in relation to the number of children. This has been provided for the help of those epidemiologists who are looking for relationships between the nature of the dietary fat and the incidence of coronary-artery disease. The uniformity in the total quantity of fat consumed is striking, though (as already stated) the Welsh take much more in the form of butter. The intake of vegetable fat is also remarkably constant (20 to 25 g. per day) at all social levels, but there is a small increase in the average intake of animal fat (from 77 to 95 g. per day) in the higher economic groups. At first sight little of importance appears to have come to light in this analysis, and the committee themselves present little comment. The working out of the correlations, if any, between these figures and corresponding data for mortality-rates is a task for the vital statisticians.

---

[1] Domestic Food Consumption and Expenditure 1956 Annual report of the National Food Survey Committee H.M Stationery Office 1958 Pp 172 9*s* 6*d*

The committee have now published records of our national diet covering the years from 1940 to 1956. Their reports are admirable summaries of the country's food intake and it is highly desirable that their surveys should continue. Perhaps, however, some variation in scope would be valuable. The committee seem so far to have concentrated on attempting to survey systematically all classes all over the country. It might be worth limiting such surveys to every third year, concentrating in the intervening years on one of the groups in which households may be especially liable not to get enough satisfactory food. Old-age pensioners and families with a large number of children are two such groups. Though they were surveyed in 1956, the numbers were too small to justify the assumption that all was well with their food-supply.

Public Health

Regrouping of Water-suppliers

In 1956 the Minister of Housing and Local Government called on water-suppliers to regroup themselves into larger and more efficient units.[1] Since then the number of undertakings in England and Wales has been reduced by 33 to 993 at the end of June. In addition, two compulsory orders and thirteen agreed orders, which together would reduce the undertakings by a further 36, were then awaiting the Minister's confirmation, the Minister had announced his intention of making three more compulsory orders, affecting 22 undertakings, and four private Bills were before Parliament.

The Minister has now called for speeding of regrouping,[2] saying that he will not hesitate to use his compulsory powers if suppliers cannot reach agreement among themselves.

Second Quarter in England and Wales

The birth-rate in England and Wales in the June quarter was high and the infant death-rate low.[3]

Live births numbered 189,159, a rate of 16·9 per 1000 population, the highest rate for a June quarter since 1949 when the rate was 17·6. Deaths numbered 124,113, a rate of 11·1 per 1000 population. The rates in the June quarters of 1957 and 1956 were 10·6 and 10·8 respectively. Deaths of children under one year of age totalled 4030, giving a record low rate for a June quarter of 21·3 per 1000 live births. The previous lowest for this quarter was 22·3 last year. In 1938 the corresponding figure was 50·3.

Anti-fly Campaign

An anti-fly campaign was held in Canterbury from July 14 to 19. The campaign included posters, the use of a loudspeaker car that toured the streets, and a competition for the best-kept dustbins. The schoolchildren were awarded prizes for the best short essays on What I Think We Should Do About Flies.

Conferences

ANÆMIA AND THE ALIMENTARY TRACT

Last week the Royal College of Physicians held the first of its new college conferences, with 117 participants, of whom 21 were invited speakers. Prof. Robert Platt, the president, explained that the programme had been arranged by Prof. L. J. Witts, Prof. J. V. Dacie, and Dr. F. Avery Jones, and that the speakers had been selected from among those who are actively extending knowledge of anæmia in its relation to the alimentary canal. Chairmen at the sessions were the President, Dr. T. C. Hunt, Professor Witts, and Dr. T. L. Hardy.

The Mouth and Œsophagus

Dr. Richard Asher (London) pointed out that the tongue is to some degree an index of the state of the rest of the alimentary tract, especially in sprue. Glossitis indicates that there is something wrong, but gives little clue to what it is, for atrophy occurs both in iron-deficiency anæmia and in pernicious anæmia, though in the latter the tongue usually appears glazed and glossitis precedes the anæmia, whereas in iron deficiency there are changes in the lips and angular stomatitis. There is doubt whether the atrophic changes in iron deficiency are due to the iron deficiency, for deficiency in any of the vitamin-B group may be followed by papillary atrophy and then by iron deficiency, while the lesions can be cured with riboflavine or with iron.

Dr. Asher recalled that A. B. Kelly and D. R. Patterson gave a full description of dysphagia associated with iron deficiency and a tendency to carcinoma of the œsophagus no less than three years before the inadequate description given by Vinson and the private communication of Plummer.

Dr. Wilfred Sircus (Edinburgh) discussed aphthous stomatitis and the syndromes of Behçet, Reiter, and Stevens-Johnson. About 20% of the population suffer sometimes from aphthous stomatitis—females twice as often as males—and nearly a fifth of the sufferers have attacks so frequent as to be virtually continuous. These ulcers can become confluent and cause severe scarring. Lesions occur on the genitalia in half the female but only 2% of male sufferers. The pathology is non-specific, but an inquiry showed that two-thirds of patients with malabsorption states had previously had severe aphthous ulceration, while 70% of sufferers from aphthous stomatitis suffered from severe anxiety states or emotional conflicts and nearly 60% were depressed. The ætiology is uncertain, but a metabolic or autoimmune process now seems more likely than a virus infection.

Behçet's syndrome is indistinguishable except that it involves the conjunctivæ and vagina: oral ulcers may precede the other lesions by several years. Recurrent herpes tends to die out as the patient gets older. Reiter's disease associates oral ulceration with urethritis and conjunctivitis. Oral pemphigus is painless but leaves lacy scars, and epidermolysis bullosa is rare. The Stevens-Johnson syndrome when fully developed has a generalised rash, with ulceration of face, mouth, conjunctivæ, and genitalia, but sometimes the lesions may be less extensive; if confined to the mouth, a macular rash develops vesicles which in 5–6 hours fuse to form bullæ, then burst and form serpiginous infected ulcers with a necrotic base and a hæmorrhagic margin.

---

[1] See *Lancet*, 1956, ii, 728.
[2] Circular 4/58.
[3] The Registrar General's Weekly Return no. 29, 1958. H.M. Stationery Office. Pp. 20. 1s. 6d.

Dr T D Kellock (London) discussed œsophageal lesions, pointing out that in the "Plummer-Vinson" (Kelly-Patterson) syndrome the anæmia seems to cause the lesion, whereas in hiatus hernia the lesion causes the anæmia In the Kelly-Patterson syndrome complete restoration to normal health is unusual (4 of 26 cases), the web remaining Rare cases of œsophageal web without anæmia or dysphagia have been seen, and it may be that the web formation is a congenital lesion and not, as hitherto thought, a consequence of iron deficiency However, 3 male patients have developed the syndrome apparently from chronic bleeding at the suture line of a gastroenterostomy, and these may be the heralds of an epidemic of this syndrome due in 15 or 20 years as a consequence of the many gastrectomies performed nowadays Among patients with hiatus hernia, anæmia is common only in the rolling (55%) or combined (28%) types Peptic ulceration of the œsophagus is rare, and occurs exclusively in heterotopic mucosa, the commonest objective finding is anæmia

In the discussion it was brought out that smooth tips to the tongue may be considered normal and that new methods of tongue biopsy may help The absence of a control series of housewives without aphthous ulcers was criticised and the excellent results of treatment with hydrocortisone emphasised

The Stomach

Prof H A Magnus (London) described the histopathology of the stomach in pernicious anæmia By the time death occurs there is severe atrophy of all coats of the stomach, often with replacement of the body mucosa by intestinal epithelium and always without any evidence of inflammation However, now that the changes can be observed during life by using Wood's gastric biopsy tube, the picture has changed Only 40% of patients show complete atrophy, 35% show severe atrophic gastritis, 16% atrophic gastritis of less advanced degree, and 9% severe gastritis with atrophy but survival of a variable proportion of chief and parietal cells, even after pernicious anæmia had been present for several years He concluded that there is a progressive inflammatory atrophic gastritis, and that this ultimately leads to complete gastric atrophy, the inflammation need not be exogenous Such stomach changes are not confined to pernicious anæmia, but if a patient with such changes lives long enough he will probably develop pernicious anæmia He also thought that a genetic nature is suggested by the history of the 20 cases of the juvenile pernicious anæmia

Dr Margot Shiner (London) described Wood's gastric biopsy tube and the intestinal biopsy tube The procedure is not entirely devoid of the risk of hæmatemesis (3%) but has never caused anxiety for the patient's life In the stomach she differentiated between gastric atrophy and atrophic gastritis of varying degrees, and in the intestine she noted varying degrees of villous atrophy with hyperplasia of the glands of Lieberkuhn Idiopathic steatorrhœa and cœliac disease display severe villous atrophy irreversible on treatment, whereas in tropical sprue and most cases of postoperative steatorrhœa the villi do regenerate when the patient is effectively treated In pernicious anæmia and in iron-deficiency anæmia the intestinal mucosa is normal, but stomach mucosa is atrophic, or atrophic gastritis is present, in all patients with pernicious anæmia, in 54% of those with iron deficiency, and in many patients with idiopathic steatorrhœa These results seem compatible with the hypothesis that pernicious anæmia is the final result of a genetically determined progressive atrophy of the chief cells of the gastric mucosa, while cœliac disease and idiopathic steatorrhœa result from an analogous atrophy of the crypt cells of the intestinal mucosa

Dr R O K Schade (Newcastle) described his technique of gastric lavage for the diagnosis of carcinoma of the stomach by exfoliative cytology The best results are obtained in early cases because after ulceration the cytological details are often obscured by debris In four years, 30 cases were diagnosed by this method when other methods failed, and in 13 the tumour was microscopic and had not started to invade Several patients had a small carcinoma as well as a peptic ulcer

In the discussion the general opinion was that exfoliative cytology of the stomach seems justified in any patient with unexplained gastric disturbances, and that although false positives may occur this procedure is the only one which can detect early cases of gastric carcinoma The cost of such tests on a large population was considered, but Dr Schade thought that it need not be excessive

It became clear that the recent work on megaloblastic anæmias has left some confusion about the best definition of pernicious anæmia in modern language Dr Sheila Callender (Oxford) said that in cases of pernicious anæmia there was evidence that one parent or the other had latent or expressed pernicious anæmia, and Professor Magnus suggested that the disease be defined as a megaloblastic anæmia occurring in a subject with a congenital chemical defect causing a progressive gastric lesion which normally continues to complete atrophy

Investigation of Gastric Secretion

Dr K B Taylor (Oxford) described the simplest indirect methods of measuring gastric secretion—the 'Diagnex' tests of gastric acid production, which can be done without passing a gastric tube, and the estimation of uropepsinogen excretion

Neither the quininium nor the azure A diagnex resins give complete correspondence with the histamine test meal Pyloroduodenal obstruction, syndromes of small-intestinal malabsorption and hurry, gastric operations, and disease of the urinary tract may affect the results, and gastric stimulation with caffeine sodium benzoate may be inadequate Even when these possible sources of error have been excluded, false positive and negative results occur The latter are unimportant, provided they are always checked by a subsequent maximal histamine test meal, but false positives are unsatisfactory In this respect the quininium test is better than the azure A, and the positive error is only 5%, which makes it a useful screening procedure in clinical diagnosis, where a finding of achlorhydria suggests pernicious anæmia or gastric carcinoma (or both) and excludes duodenal ulcer, and a finding of free acid excludes pernicious anæmia In research the test is valuable in picking out patients with defective gastric secretion

The uropepsinogen test is even easier to perform, requiring only the collection of a twenty-four-hour specimen of urine and the estimation of proteolytic activity by a comparatively simple method The levels of uropepsinogen in the urine of patients with pernicious anæmia are always very low, but similar levels may occasionally be found in subjects in whom other tests of gastric function are normal Thus the chief usefulness of the test in research is in screening subjects for more detailed investigation of gastric function, and in Oxford this has proved to be the most satisfactory single test In clinical diagnosis, since a high result excludes pernicious anæmia, it has a real value in the investigation of patients who have received treatment with vitamin B_{12} and are no longer anæmic, and in whom there are reasons for questioning the diagnosis of pernicious anæmia

Mr A W Kay (Glasgow) gave an entertaining and complete account of his augmented histamine test, showing how he established in this test that maximal histamine response occurs, by means of dose-response curves He emphasised the importance of performing the test in a standard way, paying particular attention to the time factor The maximal gastric secretory response lasts about 30 minutes and is attained 15 minutes after subcutaneous injection of histamine There was remarkable quantitative correspondence when repeated tests were done in the same subject His experience is that most patients who show no change in the pH of the gastric contents with his test have pernicious anæmia He believed, that the test is of value in determining how much of the stomach should be resected in operations for peptic ulcer, but he was dubious of its value in the diagnosis of gastric carcinoma The most interesting results he presented were of the effects of antrectomy and vagotomy on the secretion of acid by the stomach Both procedures markedly reduce acid secretory response to maximal histamine stimulation, though the number of parietal cells is unaffected Finally, Mr Kay agreed with Dr Taylor that true achlorhydria is uncommon and requires further investigation

The discussion was opened by Dr Sircus, who regarded the augmented histamine test as a major advance in investigation of gastric function In Edinburgh they have noted that steroid therapy often results in an increased response of acid secretion to histamine Dr Avery Jones (London) mentioned a patient who had hypersecretion of acid and showed no increased response to histamine this was possibly due to a secretory islet-cell tumour of the pancreas Mr Kay said he had had a similar case Professor Witts (Oxford) said that if achlorhydria is found with the histamine test it may be due to faulty positioning of the tube, and that fluoroscopic control should be done Other points discussed were the action of the antihistaminic drugs when used in the augmented histamine test, the observation by several observers that in pernicious anæmia there may be a small rise rather than a fall in the pH of gastric juice on histamine stimulation, and the value of direct measurements of pH in the stomach, using electodes in situ Mr Kay's opinion on this last method was that the results are too variable to be useful

Investigation of Anæmia

Dr Sheila Callender said that estimations of serum-iron levels alone are of little value in assessing whether a subject is iron-deficient the iron-binding capacity of the serum should be measured as well In this way, iron deficiency can be detected even in the absence of anæmia, (the *sideropænia sine anæmia* of Waldenstrom), when there is a low serum-iron level with normal or raised iron-binding capacity The value of radioactive isotopes of iron is in assessing absorption, utilisation, and turnover of iron Absorption can be measured by giving a test dose of labelled iron (and here the size of the dose is important) and measuring the amount excreted in the fæces, or by giving, contemporaneously, an intravenous dose of a second isotope of iron, and measuring the rate of disappearance of both oral and intravenous isotope from the plasma In this way a corrected plasma curve for the oral isotope can be obtained, from which can be calculated the amount absorbed from the gut Dr Callender went on to discuss the use of foodstuffs labelled with radioactive iron Such tests better reproduce normal conditions than giving a small dose of inorganic iron to a fasting patient The best test is to give a normal bulk of food with the labelled material In this way it has been shown that food iron absorption is reduced after gastrectomy, and this has cleared up the very important problem of postgastrectomy anæmia

Tests of absorption have shown that, except in steatorrhœa and after gastrectomy, the commonest cause of chronic iron-deficiency anæmia is blood-loss A " primary " failure to absorb iron is exceedingly rare Finally, she thought that in-vivo counting of radioactive iron has little value, except in the diagnosis of myelosclerosis, where counts over some site of high marrow activity, such as the sacrum, may be abnormally low

Dr D L Mollin (London) gave an account of his experience with serum-vitamin-B_{12} estimations, and the use of vitamin B_{12} labelled with radioactive cobalt, in studies of absorption The serum-B_{12} concentration, measured microbiologically by the *Euglena gracilis* method, is the best indicator of deficiency If there is deficiency of the vitamin the absorption studies, using the fæcal excretion test, or the urinary excretion test of Schilling, can be done He presented evidence that in subacute combined degeneration of the spinal cord the vitamin-B_{12} concentration in the serum tends to be lower than it is in pernicious anæmia, and that in the former, with marked B_{12} deficiency, there may be no anæmia Patients with anatomical lesions of the small bowel, such as strictures and loops, show low levels of serum-B_{12}, mostly in the pernicious-anæmia range Absorption of the vitamin is impaired and is improved only by giving antibiotics orally When the ileum is involved, there is no way of enhancing absorption, since this structure is the main site of absorption of vitamin B_{12}

Many patients with idiopathic steatorrhœa, sprue, and tropical macrocytic anæmia have low serum-B_{12} levels, but fail to respond completely to the vitamin and require folic acid as well

Professor Dacie (London) completed the session by describing experiences at Hammersmith Hospital with tests of folic-acid clearance and folic-acid absorption Dietary deficiency of folic acid is rare The types of megaloblastic anæmia which are benefited by folic acid are those associated with idiopathic steatorrhœa, sprue, pregnancy, anticonvulsant therapy, leukæmia, cirrhosis, and kwashiorkor He went on to give details of the intravenous folic-acid clearance test which seems to be a good indicator of folic-acid deficiency Thus, in steatorrhœa with megaloblastic anæmia but normal serum-B_{12} levels the rate of fall in concentration of the injected folic acid is much higher than normal In megaloblastic anæmia associated with mysoline therapy the fall-off is normal, which suggests here that the underlying defect is one of utilisation In pernicious anæmia there may or may not be concomitant folic-acid deficiency, and the test cannot distinguish between it and megaloblastic anæmia due to folic-acid deficiency alone Professor

Dacie concluded by giving an appraisal of the test of folic-acid absorption developed by Dr Chanarin, which depends on measurements of folic-acid concentration in the serum after an oral dose, the patient being saturated with folic acid previously

One of the points raised in the discussion was that radioactive iron studies alone are of no value in assessing whether splenectomy should be done or not, when there is other evidence both of splenic erythropoiesis and red-cell destruction Dr W T Cooke (Birmingham) gave his opinion that the rate of disappearance of folic acid from the serum after injection should not be interpreted in terms of tissue desaturation Dr I Chanarin (London) said that in his experience rapid clearance of folic acid occurs only where deficiency may be expected Professor Witts wound up the session by saying that in clinical practice estimations of serum-vitamin-B_{12} are seldom of value, because the patient has nearly always been given some vitamin B_{12}, that in anomalous cases labelled vitamin-B_{12} absorption tests may be useful if available, and that the application of the folic-acid tests is almost wholly a research procedure

Steatorrhœa

Dr W P H Sheldon (London), speaking on cœliac disease, said that the more severe it is, the greater is the anæmia—usually hypochromic and responding somewhat indifferently to oral iron Of 81 patients, 7 (9%) had a megaloblastic anæmia which responded promptly to folic acid He laid stress on the importance of Dr Shiner's biopsy findings and the need for further data The chief advance in knowledge, however, has been the discovery of the effect of gluten A gluten-free diet is not particularly palatable to the child, so the taste of wheat products should be retained by using gluten-free wheat starch Gluten is broken down into gliadin and glutamine, and the noxious agent is in the gliadin, but tryptic digestion to peptides does not remove it Digestion with hog's stomach does The actual substance seems likely to be a peptide-glutamine complex which may well act directly on the organs rather than only on digestion—e g , on mental processes and on growth The rate of growth increase when a child returns to a normal gluten-containing diet will show whether he has acquired tolerance for gluten Of 95 patients treated for eighteen months or more on a gluten-free diet, 72 continued normal growth when reverting to gluten, 11 relapsed, with full symptoms, and 12 showed intolerance only by slowing of growth

Dr W T Cooke (Birmingham) would discourage the use of such terms as malabsorption syndrome, sprue, and jejunoileal insufficiency, because the various clinical states associated with disturbances of the small intestine are taking on distinctive patterns, some with features not necessarily due to malabsorption but rather to malutilisation Moreover, the term adult cœliac disease might be used to denote idiopathic steatorrhœa (with its implication that steatorrhœa is the most important factor), or non-tropical sprue (with its implied ætiological association with tropical sprue) It is justifiable to regard tropical sprue, with its different response to treatment, biopsy findings, folic-acid metabolism, and prognosis, as a specific clinical entity In all but the occasional patient three investigations are needed for a diagnosis of steatorrhœa In patients taking a normal mixed diet, a daily fat content of more than 6 g in stools collected for three to six days can be considered abnormal Careful radiological examination, with either flocculating or non-flocculating barium, is essential, for only by this method can many patients with apparently similar clinical symptoms be differentiated Thirdly, complete hæmatological investigation is required A persistently normal blood-count is strong evidence against adult cœliac disease Patients with steatorrhœa due to pancreatic lesions rarely have anæmia unless they are also malnourished The anæmia of adult cœliac disease is due to iron, vitamin-B_{12}, or folic-acid deficiency, either separately or combined Upsets in folic-acid metabolism are important Low serum-B_{12} levels are found in rather more than half the patients In regional ileitis, 42 patients out of 80 had low serum-B_{12}, and the impaired absorption could almost always be restored by steroid therapy The finding of 12 megaloblastic anæmias in 130 patients with regional ileitis again emphasised the importance of radiology Among the laboratory examinations, glucose-tolerance tests and carotene and vitamin-A tests give little help, but the xylose-tolerance test appears useful in separating the patients with adult cœliac disease from the other disorders Jejunitis, with its tendency to resolve, may simulate adult cœliac disease, since absorption of folic-acid in the jejunum may be grossly deficient Three more recent investigational techniques—intestinal biopsy, the folic-acid excretion test of Girdwood, and the response to gluten-free diets—make it evident that adult cœliac disease is a distinct clinical entity It is probably a familial constitutional enzymatic defect, embracing the pteroylglutamate complexes, though whether it is sited in the intestinal cell or in the liver is not evident

Dr J Badenoch (Oxford), after reviewing earlier observations on the anæmias associated with stricture and blind loops, described his own work on the intestinal diverticula He laid stress on the occurrence of diarrhœa, though only half the patients had steatorrhœa Some patients will present with anæmia indistinguishable from pernicious anæmia and be so treated The necessary radiological studies are sometimes difficult because the barium does not enter the narrow-necked diverticula Surgical treatment is unsatisfactory and it is better and safer to treat these patients by medical means Vitamin-B_{12} should be given monthly, and daily supplements of calcium gluconate 15–20 g , folic acid, and vitamins In the acutely ill patient, broad-spectrum antibiotics should be administered, but Dr Badenoch did not favour their continued administration Prednisone may also bring about remission

In the discussion, Professor A W Woodruff spoke of the difference in prognosis between tropical sprue and the disorders occurring in temperate climates Dr Callender reported dramatic increase in iron absorption in cœliac disease treated with prednisone, and in a child the initiation of gluten-free diet increased the absorption from 2% to 40% Dr A Doig (Edinburgh) recalled Girdwood's demonstration that bacteria from intestinal diverticula will take up vitamin B_{12} but actively produce folic acid

Dr P B B Gatenby (Dublin) said that, in reports on the treatment of iron deficiency, ferrous sulphate, ferrous gluconate, and ferrous succinate had all apparently induced much the same rate of hæmoglobin synthesis, but intolerance—possibly due to a higher dosage—was much commoner with ferrous sulphate Among 4000 pregnant women he found 350 with a hæmoglobin below 10 g per 100 ml Of these, 300 could take ferrous sulphate with good results Of the 50 who were intolerant, 20 did not benefit from other oral iron preparations and needed parenteral administration In late pregnancy the rate of hæmoglobin regeneration is much the same whether intravenous or intramuscular iron preparations are used, but on the whole 'Imferon' is the treatment of choice The indications for parenteral therapy are gastric intolerance, gastrointestinal disease (such as ulcerative colitis), certain types of steatorrhœa, rheumatoid arthritis, late pregnancy, and possibly for the replenishment of iron stores in recurrent anæmia

Prof L J Davis (Glasgow), whose paper was read in his absence, had reviewed 374 megaloblastic anæmias under his care in 1948–51 Of these 315 had pernicious anæmia the other diagnoses were malabsorption states (20), pernicious anæmia in pregnancy (16), nutritional deficiency (5), and anticonvulsant therapy (1), leaving 17 undetermined Of 73 patients treated with vitamin B_{12} by mouth combined with intrinsic factor, 20 relapsed He concluded that oral preparations are unsatisfactory and that regular parenteral therapy with B_{12} is best. He recommended 1000 µg followed by 250 µg weekly until blood-levels are normal, and therafter monthly 105 patients were treated with single doses of 1000 µg every three months, but by the end of this period their serum-B_{12} was approaching abnormally low levels He emphasised the dangers of folic acid in these patients and described the blunderbuss therapy sometimes advocated

Dr C F Hawkins (Birmingham), speaking of steatorrhœa, referred to the difficulty of assessing results of treatment in a condition which can show such dramatic and unexpected remissions With the usual restriction of fat and a high-protein diet, at least 70% can expect to be well enough to do their work satisfactorily Steroid therapy brings temporary improvement, but relapse is likely when it is discontinued In conjunction with Dr J M French, he has obtained clinical cure in 16 out of 22 patients Often this effect was quickly manifest, though it could take months Most striking was the effect on the incapacitating weakness and lassitude In all patients the blood-picture became essentially normal without any other therapy He ascribed failure of a gluten-free diet to four causes—the wrong diagnosis, insufficient time, incomplete diet, and unknown reasons As to these last, intestinal allergy might possibly explain the radiological pictures, a folic-acid deficiency might be present, or there might be an upset of glutamine-peptide complex

In the discussion, Dr Discombe wondered whether it was necessary to aim at a 1 2% increase of hæmoglobin per day when half this is sufficient He gave 65 mg elemental iron (one tablet) daily for six months to blood-donors who were anæmic Their hæmoglobin was restored to normal in three months and he had no difficulties with intolerance

Alimentary Bleeding

Dr George Discombe (London) discussed tests for occult blood in the fæces Benzidine has caused bladder cancer in those engaged in its manufacture and will therefore become a "museum piece" Its place can be taken by orthotolidine, which gives better results Dr Discombe has found both 'Occultest' and 'Hæmtest' tablets satisfactory The former is much more sensitive, and he favours a sensitive test for occult blood Those with a positive result can then be carefully examined with dietary and medicinal precautions He felt that the number of false positive results from the peroxidase in the stools had been exaggerated, but to ensure accurate results it is necessary to render oxidising enzymes inactive. In the Harrison benzidine test this has been achieved by boiling, which has always been the most troublesome feature of the test. Treatment of the stools with 1% sodium azide (a poison) provides an alternative and easier way of inactivating peroxidase Dr Discombe then described some promising but provisional results of testing for occult blood with orthotolidine after preliminary treatment of the stools with sodium azide If these results are confirmed, a test will be available whereby it will be easy to test for occult blood in the side-room—"safer, cleaner, quicker and cheaper" than testing in the laboratory

Professor Witts, speaking on anæmia after gastric operations, estimated that since 1948 some 100,000 persons in England and Wales must have undergone a partial gastrectomy As iron-deficiency anæmia almost inevitably follows this operation, the problem must be a considerable one The importance of bleeding in the ætiology of such anæmia is disputed It may be episodic, and a sudden fall in the hæmoglobin after operation should suggest blood-loss But the main mechanism seems to be a failure in the absorption of iron Though partial gastrectomy reduces the size of the stomach and the amount of hydrochloric acid it secretes, experiment has shown that there is no defect in the absorption of organic and inorganic iron (given on an empty stomach) The diminished absorption seems to be due to the impaired function of the stomach as a "hopper" for holding iron and food while the iron is converted from the ferrous to ferric state and absorbed Another contributing factor is the reduction in the amount of food which people take after gastrectomy Any gastrectomy will reduce the area secreting intrinsic factor, and after partial gastrectomy such persons tend to have a low level of serum-B_{12}—though (in those cases with a macrocytic anæmia) not quite so low as in true pernicious anæmia

In iron-deficiency anæmia after partial gastrectomy, parenteral iron is often the treatment of choice If iron is given by mouth, it should not be given in tablet form, for the tablets may be irritating and may hurtle through the stomach.

Pernicious anæmia is inevitable after a total gastrectomy, but relatively few cases are seen, because (1) resections are very seldom absolutely complete and (2) others are often treated with vitamin B_{12} from the time of operation B_{12} should be given in all these cases, supplemented with iron, though iron deficiency is not such a special problem in these cases as after subtotal gastrectomy If there is no response to B_{12} and iron, the possibility of a blind-loop syndrome should be considered

Dr Avery Jones reviewed the problem of unexplained hæmorrhage from experience of 2526 cases of alimentary hæmorrhage admitted to the Central Middlesex Hospital in 1941–47 He emphasised the importance of what he termed the "acute lesion group" as a cause which will be missed unless early gastroscopy is carried out This group accounted for nearly a third of those in his series The lesion is usually an acute ulcer but occasionally a gastrostaxis may be found—not infrequently around a stoma Acute ulcers most often occur on the posterior wall or the lesser curvature, they have an equal sex incidence, but in men appear more likely to become chronic. With early gastroscopy and a careful search for general medical causes of alimentary hæmorrhage, he was able to explain the cause of the hæmorrhage in half the cases in the X-ray-negative group But he emphasised the importance of following-up this group, for he has later been able to show a lesion in 24% of these cases—usually a peptic ulcer but even some new growths

An exhaustive list of the causes of alimentary hæmorrhage included food allergy a fellow of the college has a hæmatemesis each time he eats onions The Mallory-Weiss syndrome can be diagnosed by a history of vomiting, from whatever cause, followed by the vomiting of bright red blood from splitting of the longitudinal fibres of the lower œsophagus Among other disorders, von Willebrand's disease should be considered as a possible cause of recurrent bleeding, and pseudoxanthonum elasticum is a rare possibility Aspirin plays a significant role in bleeding, not only by producing an acute lesion but also in provoking a chronic ulcer to bleed It may also be found to be the cause of unexplained cases of recurrent anæmia

In reply to a question by Professor Witts, Dr Avery Jones gave advice on what to do about the difficult case of recurrent alimentary hæmorrhage for which no cause can be found after careful investigation He advised a laparotomy at the time of bleeding

PÆDIATRIC SURGERY

A striking feature of the meeting of the British Association of Pædiatric Surgeons held in London last week under the presidency of Miss Isabella Forshall was its cosmopolitan character This was particularly evident at the dinner in the Apothecaries Hall, when brief speeches were made by representatives of many European countries, as well as Japan, Australia, and the United States [1] Several countries were able to report growing recognition of the importance of pædiatric surgery, and the recent appointment of Mr A W Wilkinson to the newly created chair of pædiatric surgery in London was evidence to those from abroad that such recognition is not lacking in this country

Respiratory Emergencies

For his Moynihan lecture at the Royal College of Surgeons Dr Willis Potts (Chicago) chose the subject of Respiratory Emergencies in the Newborn In some infants, he said, the emergency is recognisable as such and the urgency of treatment is unassailable Among this group he described cases of tension pneumothorax or tension cyst where a child's life can be saved by aspirating 50 c cm of air from the chest and having the needle and syringe ready for a further aspiration should this be necessary before definitive treatment can be established Another condition in which the urgency is sometimes overlooked is congenital diaphragmatic hernia The amount of bowel in the chest may not be sufficient to cause serious distress at first, but any sudden increase in intra-abdominal tension can force more bowel into the chest, and kill the child in next to no time The one special examination which is likely to help more than any other is a good upright anteroposterior and lateral X-ray film of the chest, and the emphasis in this sentence is on the two words " upright " and " good " A horizontal radiograph is far less useful, and a poor radiograph may make it impossible to distinguish between cases in which major surgery is essential and others where less radical measures may suffice

The preoperative and postoperative management of the newborn in respiratory distress is going to depend very much on the quality of the resident medical staff and the nursing staff, and Dr Potts drew attention to the importance of having an emergency tray with endotracheal tubes, fine plastic suction tubes, and above all a laryngoscope in every ward in which these infants are cared for Such apparatus is useless unless the medical staff who are first called to the child by the ward sister are adept at laryngoscopy and the insertion of an endotracheal tube in infants Every resident in a department dealing with surgical problems in infancy should know how to handle this instrument

Meningoceles

If the Moynihan lecture by Dr Potts was directed mainly to management of conditions endangering life, several papers were concerned with the rehabilitation of infants suffering from spina bifida and its complications How often a mother brings a child to the outpatient clinic at the age of 3 or 4 years with a large meningocele, hydrocephalus, deformed legs, and an infected dilated urinary tract, with the story that the doctor told her that the baby would die before 9 months of age, or that the welfare clinic assured her that she would not rear him above 2 years of age! In his review of spina bifida cystica Dr K M Laurence drew attention to the large number of cases who are certainly alive at 8 years of age and may well live very much longer This should bring to all those who meet this serious incapacitating condition the realisation that they should help these children as much as possible The meningoceles can be dealt with in the neonatal period, and there is something to be said for this instead of leaving them until 18 months or 2 years of age as advocated by Ingraham and Motson True, the child may develop hydrocephalus, but, thanks to the pioneering work of Spitz in Philadelphia there is a good chance of controlling this condition and allowing brain development to take place The technique of inserting a Spitz-Holter valve was demonstrated at the meeting, and this procedure is now done in three or four centres in this country

Two aspects of myelomeningocele which are usually neglected are the problems of the bladder, and the problems of the lower limbs Mr D F Ellison Nash has put forward suggestions for the management of these babies, and there is little doubt that attention should be paid to the bladder at the earliest possible moment so as to prevent the infection of residual urine He described his technique for plication of the urethra, which has some place in bladder control in these serious cases

Mr W J W Sharrard propounded some stimulating views on the dislocation of the hip which so often accompanies myelomeningocele He had come to the conclusion that this was essentially a paralytic dislocation, since the muscles which were paralysed were exactly the same as those which are paralysed when dislocation of the hip complicates poliomyelitis

The management of this dislocation must therefore be based on principles differing from the management of the ordinary congenital dislocation of the hip, and Mr Sharrard was able to demonstrate that a well-thought-out and long-term plan of treatment would give some of these infants the chance of standing upright and walking

Œsophageal Atresia

In his Simpson-Smith lecture, delivered at the Hospital for Sick Children, Great Ormond Street, Dr Willis

---

[1] After Sir James Paterson Ross had replied for the Guests, the following spoke informally Dr Yanagisawa (Tokio), Prof Fritz Rehbein (Bremen), Dr Hartl (Linz, Austria), Dr Wanda Poradowska (Warsaw), Dr Kafka (Yugoslavia), Dr Mázal (Brno, Czechoslovakia), Dr Willis Potts (Chicago), Prof A J Craig (Malta), Dr Matti Sulamaa (Helsinki), Dr Petterson (Göteborg, Sweden), Dr Juan Lestache (Madrid), Professor Soave (Genoa, Italy), Mr Russell Howard (Melbourne, Australia), Prof Max Grob (Zürich, Switzerland), Dr Akkary (Alexandria, Egypt), Dr D Vervat (Rotterdam, Holland), Dr Winkel-Smith (Copenhagen, Denmark), Dr N Tzemailas (Athens, Greece)

POTTS discussed the factors which had contributed to the gradual lowering of mortality in the treatment of œsophageal atresia in his unit so that the recent figures showed that three out of four patients were surviving In his large series of 148 cases, Dr Potts was able to pick out a number of factors which he thought had contributed to the improving results

The following morning, Prof **FRITZ REHBEIN** (Bremen) discussed the complications in the treatment of œsophageal atresia and Mr **R B ZACHARY** (Sheffield) presented two cases of complete absence of the œsophagotracheal septum During the discussion on these cases, and on Dr Potts' lecture, the discussion centred round many aspects of the treatment of œsophageal atresia including the choice of transpleural or retropleural approach, the routine use of a fine polyethylene cannula through the nose and down the œsophagus into the stomach for feeding purposes, and the problems connected with anæsthesia

SARCOIDOSIS

AN international symposium on sarcoidosis, arranged by the British Postgraduate Medical Federation, was held in London from June 30 to July 2

Dr **L SILTZBACH** (New York) felt that a definition of sarcoidosis should include the following reference to the Kveim test

> "The intracutaneous Nickerson-Kveim test employing a sarcoid tissue suspension of known activity and specificity is microscopically positive in a majority of instances among patients with florid lesions The test is of value in the absence of other tissue biopsy confirmation of the diagnosis or when clinical and histological findings conflict"

Dr **J G SCADDING** restricted himself to a morbid-anatomical definition to include the tissues most frequently involved and the histological changes observed in those tissues Dr **A D THOMSON** pointed out that a pathologist could only report that the histological changes were consistent with the diagnosis of sarcoidosis, for sarcoid tissue was a non-specific response to a variety of agents Dr **O REFVEM** (Oslo) enumerated several chemical, infective, and neoplastic processes known to provoke these local sarcoid-tissue reactions In reviewing the vexed problem of ætiology, Dr **J TURIAF** (Paris) opposed the view that sarcoidosis was related to tuberculosis

Epidemiology of the disease in Great Britain has so far been unrewarding, but Dr **J CHAPMAN** (Dallas, Texas) surveyed its global distribution Dr **M CUMMINGS** (Washington) provided interesting data based on its prevalence in the South-Eastern region of the United States He and his coworkers have long been aware that forested areas might provide some clue More recently they have observed that pine pollen has certain chemical similarities to the tubercle bacillus, including acid-fast staining properties A pine-pollen extract provoked delayed-type (tuberculin-type) skin-test reactions in half of a group of patients with sarcoidosis, and it also produced local tuberculoid granulomas in animals Further immunochemical and epidemiological investigations are in progress to definite the substance and its possible role in the disease Dr **W G STRAWBRIDGE** (Cardiff) drew attention to a long-chain fatty acid which he had uncovered in sarcoid tissue Interesting and important work remains to be done to define the relationship of this substance to Dr Cummings' pine-pollen extract, and their possible identity with the active fractions of Kveim antigen

Dr **W J WILLIAMS** (Cardiff) outlined his painstaking endeavours to identify the chemical composition of the inclusion bodies in beryllium disease and concluded that it was probably calcium carbonate Dr **I B SNEDDON** (Sheffield) related his experience of a beryllium skin-patch test. It was similar to the Kveim test in that a sarcoid granuloma appeared, within a month, at the site of application of beryllium, it was specific for berylliosis

Prof **C E DENT** emphasised the value of an oral cortisone test for differentiating hypercalcæmia due to sarcoidosis from that due to a parathyroid tumour in the occasional difficult problem case Whereas cortisone did not influence the serum-calcium level in the presence of a parathyroid tumour, it produced increased fæcal excretion and a fall to normal of the serum-calcium level in sarcoidosis

Dr **S LOFGREN** (Stockholm), who pioneered the view that erythema nodosum and bilateral hilar lymphadenopathy are early manifestations of sarcoidosis, described his experience of this syndrome in Sweden and also the results of renal biopsies in patients with hypercalcæmia due to sarcoidosis In his experience, serum-uric-acid levels were higher in patients with sarcoidosis than in those with tuberculosis or in other control subjects Calciferol provoked elevation of serum-uric-acid as well as serum-calcium levels

Dr **H LUNDBACK** (Stockholm) had studied sarcoid tissue in culture and illustrated his communication with beautiful photomicrographs Dr **CUMMINGS** drew attention to similar studies by his colleague, Dr H Bernton It was hoped that such studies would yield ætiological information or alternatively provide a system for reproducible immunological experiments

Dr **CLIFFORD HOYLE** based his prognosis of the various manifestations of the disease on the course which he had personally followed for many years in a large series of patients He emphasised the high rate of spontaneous clearing of bilateral hilar lymphadenopathy Dr **M SONES** (Philadephia) had followed the course of 200 patients for twenty years There was a mortality-rate of about 10%, mainly from pulmonary heart-disease

Dr **H ISRAEL** (Philadelphia), who had collaborated with Dr Sones in this long-term follow-up, felt that the pattern of disease in their Coloured patients was basically similar to that observed in White Europeans One notable difference was the comparative rarity of erythema nodosum in America

Dr **D G JAMES** outlined the indications for corticosteroid therapy in sarcoidosis, stressing eye disease, disfiguring skin lesions, hypercalcæmia, and a worsening chest radiograph as the most important Yardsticks for measuring the response were clinical, histological, and radiological Steroids were the only drugs which favourably influenced all three By these criteria, triamcinolone was proving just as effective as prednisolone, and a new drug SQ 9727 (Squibb) showed equal promise Mr **R P CRICK** emphasised the value of early corticosteroid therapy for the ocular lesions Dr **INGRID GILG** (Copenhagen) claimed good results from the use of calciferol in patients with cutaneous sarcoidosis attending the Finsen Institute Prof **K WURM** (Freiberg) had observed spontaneous improvement in 16 of 18 pregnant patients He had never seen deterioration during pregnancy, although some relapses had occurred after parturition

During the conference, Dr **K CITRON** and Dr Scadding exhibited the results of their investigations of immunological responses in sarcoidosis

In England Now

A Running Commentary by Peripatetic Correspondents

MORE excitement in Cockaignshire, where Dr. X. has again been hauled before the Executive Committee on a charge of over-prescribing. It seems he was called to a gipsy girl who lived on a barge which, said Dr. X., like a burnish'd throne, burn'd on the water, the poop was beaten gold, purple the sails, and so perfumed that the winds were love-sick. (Here the Chairman over-ruled Mr. Crumb, the Ministry of Health's representative, who remarked that according to his notes, the winds were N.N.E. and blowing a half-gale.) His patient, resumed Dr. X., had been advised that if her nose had been shorter, the whole history of the world would have been different, and she now requested a plastic operation on the N.H.S. in a gallant attempt to improve the situation before it was too late. She agreed with the doctor that she had rather left things until the last moment, but said she had been convalescing from a nasty asp-bite.

The nobility of this *amende honorable* by a beautiful refugee of royal blood had so moved him (declared Dr. X.) that he had unhesitatingly continued the treatment ordered by the lady's previous doctors, viz.:

R Orient pearls *ii*
Vini ad ℥ ½
F. Sol., Sig. ℥ ½ t.d.s., p.c.

Unfortunately the only solvent for Orient pearls, apart from battery-acid, appeared to be 'Zippo' vitaminised port-type tonic wine. This fluid, he claimed, should therefore be regarded in this case as a medicine. How *could* he, he asked (opening the door to admit two workmen carrying a roll of carpet), how *could* he disappoint this brave little woman? Her offer was sublime, a veritable widow's mite, and she had insisted in attending there today although her poverty was such that, as they would see, she had literally nothing to wear except the carpet she was rolled up in. This revelation disturbed the committee considerably.

Mr. Crumb, on behalf of the Ministry, said that the female nevertheless appeared to be adequately nourished and could he assume that the figures 36-24-36 he had just been given were her N.H.I. number? Dr. X. (said Mr. Crumb) had referred them to Herodotus, Plutarch, and certain insolvent Elizabethan playwrights, but what were they compared with Statutory Instrument 1234 M.H., E.C.S. (M.) 4a/36/48? Also (continued Mr. Crumb) the cost to the country of Dr. X's prescription was £1200 for one week's course of Orient pearls, plus 3*s.* 9*d.* for the zippo tonic wine. Admittedly there was 2*d.* back on the bottle, and the Ministry would never condone any N.H.S. patient being deprived of any necessary medicament, no matter how costly, but he had been advised that nitric acid (fuming) was quite as effective a pearl-solvent as zippo, and was equally palatable. The prescription of zippo in this case was extravagance and he asked that 3*s.* 9*d.* be deducted from Dr. X's next cheque, and, while again emphasising that the Ministry would never condone, &c., &c., he recommended that Dr. X. be also fined £1200 for over-prescribing.

* * *

A little charm, she maintained, is worth a lot of knowledge, even in examinations. At the sight of her the most hardened and cantankerous patient would announce that the lump in his neck was a carcinoma of thyroid treated with radio-iodine, or that he had fibrosis of the left upper lobe, "and don't forget to say I have deviation of the trachea." The ladies were equally obliging and whispered words of encouragement and helpful information. "The tall one always asks about me big toe, and 'e wants yer to say 'Gout, which is rare in a woman of this age.' I'm not supposed to say, but I like your face."

But the fortune in her face was not infallible. The last examination she ever intended to take arrived before her social engagements had allowed her time to read the section entitled Neurology. In spite of appealing glances and powerful silent prayers she was led past a coughing patient whom she had met in a previous examination and whose acquaintance she would have been delighted to renew, and was left with an unpromising character who was obviously neurological. Her opening gambit, a bright "What's the matter with you?" received the sullen reply "That's *your* guess." A few ineffective taps with a patella hammer and a jab or two with a pin brought into her mind, as though by divine inspiration, the word syringomyelia, a condition which she had heard was common in examinations but about which she knew nothing.

"Have you got syringomyelia?"

"That's *your* guess."

It was hopeless, and time was passing. She looked round. The examiner was out of earshot. She jabbed again with the pin and said fiercely: "I don't believe you have syringomyelia. I think you have syphilis."

This provoked the desired response. The patient, in high dudgeon, announced that he most certainly had not got syphilis, and that he had syringomyelia, which he could prove because he had dissociated anæsthesia on both sides of the body, &c., &c. He knew all the answers, and so, at the end of five minutes, did she.

She presented the case flawlessly. But rough justice was done. The examiner, equally impervious to her undoubted charms, while agreeing with her diagnosis and physical signs, felt unable to pass her because of her complete inability to describe any form of syphilis that might be considered as a differential diagnosis.

* * *

In appearance and habits we are in no way remarkable, and it has been our ambition to proceed inoffensively through life, breathing quietly through our nose and causing as little fuss as possible. But recent events have conspired to present us to the world as a wrecker, a vandal, a despoiler of other men's property. We are having Plastic Trouble.

The first manifestation of our Trouble occurred while we were on holiday in Devon. We were sitting comfortably one morning on the black plastic seat, placidly admiring the black bath and the lurid murals of orange flames, when we were startled to hear a sharp crack and to have our equilibrium momentarily disturbed. When we looked, what should we find but a comminuted fracture of the left posterior quadrant of the seat. They were very pleasant about it, but we said no, it was entirely our fault, and we must insist on paying (thirty-five bob it cost us, too).

The second manifestation was a couple of months ago, while we were visiting a friend of ours in the pathology department. A nice white job it was, but white or black is all the same to our Trouble, so long as it is plastic, and crack it went just like the first. On this occasion we were slightly less inclined to take an altruistic stand on the matter of payment, but fortunately our friend made little of the occurrence, and we wrote it off to departmental maintenance.

The third attack took place last week, in the newly opened establishment in connection with our hospital library. This time we did not hesitate. As soon as we heard the now familiar crack we made haste to sneak out as unobtrusively as possible, leaving our senior assistant surgeon, the only other occupant of the library, to take the blame.

We find all this very disturbing, and the thought that at any time we must expect to hear the short sharp report marking the end of number four is interfering with our sleep. We had no difficulties of this kind in our youth. We remember a large wooden throne on which we were wont to spend many happy hours singing to the illustrated papers which were stored in lockers on each side of the business portion of the machine. At school the seats were made of inch-thick timber, and in later years we had occasion to patronise a cold stone contraption in a Scottish castle. A man could relax, without fear of personal injury or financial embarrassment, when seats were solid affairs made of natural material and not flimsy wafer-like contrivances whipped up out of coal and air and casein.

Letters to the Editor

CHILDREN IN HOSPITAL

SIR,—I am so fully in agreement with your leading article last week, "What Hospitals for Children ?", that on reading it I felt as if I had written it myself Your recommendations, and those of Professor Illingworth for the care of children in hospital, are nearly all standard practice at Queen Mary's, a general children's hospital of 550 beds of which I have been physician-superintendent since 1953, and we could indeed add to these recommendations from our experience here I am also well aware from personal experience of the difficulty of working to these high standards for children in a small children's ward of a general hospital, or in a purely long-stay children's hospital

While your editorial was in the press, we were informed by the South West Metropolitan Regional Hospital Board, out of the blue and without consultation, that they proposed to close Queen Mary's Hospital for Children, Carshalton, Surrey, within the next few months, and to use the building for another purpose for which they have been unable to secure an allocation of capital from the Ministry of Health.

Before my appointment five years ago I was assured that it was the regional board's intention to develop Queen Mary's fully as a general children's hospital Since then great strides have been made, and the hospital is now fully staffed and equipped to deal with all types of case at all ages from 0 to 16 Queen Mary's has at present 550 beds, with a further 150 in reserve Although more than half the beds are occupied by long-stay cases, 82% of the *children* discharged have been in hospital for less than two months

The board have always worried about the financial implications of Queen Mary's being filled to less than capacity, but they have never shown any serious interest in, or appreciation of, the fundamental problem of children's bed distribution with which your editorial deals

There is no member of the board or of the board's staff who is competent to advise the board on matters of pædiatric planning There is no pædiatric adviser There is no pædiatric committee When a year or two ago I asked if the board would consider seeking expert advice on certain of their pædiatric problems, the Chairman's answer was "No" It seems most unlikely therefore that the board have on this occasion been expertly advised before concurring with the Ministry's suggestion of abandoning, for the sake of temporary financial convenience, the largest general children's hospital in southern England I very *much doubt* whether the Ministry themselves took expert advice before pressing this recommendation, with financial strings attached, on the regional board

I am not one of those who think that it is the board's policy to abandon children's hospitals in favour of small children's wards in general hospitals I would make a graver charge It is that neither the board nor the Ministry of Health have any policy at all on the subject, and do not consider the question of very great importance This is certainly the impression which I have gained after five years as physician-superintendent of the board's only large children's hospital

I have long made plain to the board my view that if they decided to close small children's wards in general hospitals near Queen Mary's, to close children's fever beds, and to prohibit wherever possible the treatment of children in adult wards, the continuation of Queen Mary's as a 550–700-bedded children's hospital would be justified in even cold financial terms and you have already cogently argued in your editorial how much this would mean in terms of improvement of the service given to the children concerned. I do not think that the regional board have taken any serious steps to obtain the facts and figures on which alone an accurate assessment of this possibility could be made This is, in any case, only the most obvious of several ways in which the continuity of the work of this great children's hospital (which deals with 4300 inpatients, 11,500 outpatients, and 2400 surgical operations per annum) could be secured There is not the space here to refer to the implications of this policy on the training of general nurses, which, however, I have recently discussed elsewhere [1]

This decision does not of course affect Queen Mary's alone It is a direct threat to the continuation of the Register of Sick Children's Nurses (Queen Mary's Nursing Training School provides 15% of the annual entry to this register), it would constitute a strong precedent for a reversal of the policy which you advocate in your editorial, and it would make it impossible for the education authority to implement the Minister of Education's recent recommendation about education in hospitals, for most of the children in the South West Metropolitan area

I find it hard to believe that the Ministry and regional board realise just what it is that they are proposing to throw overboard In its combination of acute medical and surgical services with all the special provision necessary in special units for the treatment of poliomyelitis, rheumatism, cerebral palsy, muscular dystrophy, and fevers, and with its hospital school staffed by 40 general and specialist teachers, Queen Mary's provides a better cross-section of pædiatric care than is available anywhere else in the country This is well recognised by the matrons who subsequently employ nurses trained at Queen Mary's, by the medical schools of Guy's and St Thomas's Hospitals, whose one week of residence for an intensive course at Queen Mary's is recognised as important, and is highly valued by the students, and by the Surrey Education Authority who well recognise that it is only in a combined acute and long-stay hospital of this kind that they can efficiently give the services which are expected of them in the education of sick children

I do not at the moment know exactly what form our swift response will take, but I do not believe that this far-reaching proposal, taken, as I believe, without any real understanding of its effect upon the care of sick children, or of the future of pædiatrics or pædiatric nursing, will be allowed to stand

Queen Mary's Hospital for Children,
Carshalton, Surrey

DAVID LAWSON
Physician-Superintendent

SIR,—A warm and sincere welcome to Professor Illingworth's article and your leader of July 26 I agree with almost everything that is said, except at one point where Professor Illingworth does not go far enough He commends daily visiting, which, to me, is as archaic as no visiting at all In my view—and I speak with nearly ten years' experience—unrestricted visiting solves most of the problems of children in hospital

I can best make clear what I mean by unrestricted visiting by quoting from the pamphlet we give to parents It states "You may visit when you like, as often as you like and you may stay as long as you like" We accept any adult visitor and, with supervision, children as well

As there is no limit on length of visit, we are prepared to and frequently do provide residential accommodation for the parents I stress the plural, since it is usually the mother who is admitted with the child, but in certain cases, usually bulbar poliomyelitis in older children, both parents may want to live in the hospital for several days In the matter of admitting parents we do not specifically consider the age of the child, and the only judges of whether they live in or not are the parents themselves

---

[1] The Future of Children's Hospitals, *Health Horizons*, summer edition, 1958

Recently we have made a tentative advance from this position, and are trying out the idea of admitting not only the child and its mother, but her other young children as well, for let it be remembered that when a mother comes into hospital with one child, others left at home are deprived of her presence

What we claim for our system is its extreme flexibility, for, as Professor Illingworth points out, the reaction of children (and one might add parents) varies greatly where admission to hospital is concerned Obviously, if the facilities we provide were abused, chaos would result, but I would point out that parents are not the congenital idiots that is sometimes supposed Moreover, hospitals are run for the benefit of the population and not for the convenience of the medical and nursing staffs, and as far as the former is compatible with efficiency it must take precedence over the latter Our experience shows that the more consideration we show for parents' requirements the more consideration they show for us I have by no means achieved all that I should like in this direction, but our modest advance has convinced all concerned that nothing but good has come out of it

May I make a plea that daily visiting is not a target to be aimed at but something to be discarded as insufficient for its purpose

Tunbridge Wells N M JACOBY

SIR,—I should like to make two comments on the excellent and understanding article by Professor Illingworth and the leader in the same issue

First, Professor Illingworth appears to lay inadequate stress on the fact that nearly all children, and certainly those over 6–7 years of age, will be immensely reassured by some logical explanation in simple terms, preferably by a doctor, of the reasons for their stay in hospital As patient and doctor come to know each other better, it is possible and profitable to discuss the problems more fully, to give reasons for the treatment applied, and for the length of stay in hospital The child's understanding of these problems and their discussion is almost always underestimated

Second, your leader, in essence, contains a plea for the centralisation of pædiatric care—for all the very good reasons given However, while this may be practicable in urban areas, it is much less possible in many regional hospital areas because of the enormously increased difficulty of parental visiting with the longer journeys to be made Surely Professor Illingworth's admirable plans for the segregation of all children into their own wards in community hospitals should be followed by a period of reassessment and careful thought before segregation into regional pædiatric hospitals "A relatively small number of big pædiatric hospitals" "in each region" might well cause surprisingly great hardships in visiting

East Grinstead, Sussex RUSSELL M DAVIES

SHOCK

SIR,—Discussions on shock tend to be somewhat kaleidoscopic, each successive view being coloured by the particular interests and experience of its contributor The impression received by the student is necessarily confused, and lacks definition The following is an attempt to define shock in simple terms

The primary function of the blood is to carry oxygen to all parts of the body To this end we are provided with a pump which drives ten pints of blood through an elaborate system of pipes at an appropriate pressure An abrupt fall in this pressure is called shock Shock is acute hypotension This definition has the virtue of impressing on nurses the importance of blood-pressure readings, it covers every conceivable kind of shock, and it has the additional merit of being completely true

The pressure can be lowered in three ways and in three ways only

(1) By weak action of the pump (e g, coronary occlusion, injection of thiopentone, or emotional impact)

(2) By diminishing the blood-volume (i e, loss of blood, plasma, or electrolytes)

(3) By increasing the diameter of the pipes (e g, the vasodilatation which follows an adrenal crisis, the induction of hypotensive anæsthesia, or the development of profound toxæmia)

The clinical features of types 1 and 2 are almost identical, and are associated with compensatory vasoconstriction This vasoconstriction is a mixed blessing It makes the patient look distinctly poorly, and is thus an aid to diagnosis It makes him feel cold, and led us, not so long ago, to warm him up with blankets, hot-water bottles, and paraffin stoves—which is clearly absurd It may still tempt us into operating on patients who have lost a great deal of blood without, as yet, becoming shocked They *will* become shocked if we operate on them

The clinical features of type 3 are entirely different, and rather deceptive The patients are not very pale, but they are slightly cyanosed, the temperature may be raised, and the skin is warm Diagnosis, with a sphygmomanometer, is quite easy—provided one remembers to use the sphygmomanometer

Many cases of diffuse peritonitis combine the features of types 2 and 3, the fluid loss competing with the toxæmic vasodilatation

The treatment of shock is an essay in reason We give blood to the wounded, plasma to the scalded, and electrolytes to those with vomiting, diarrhœa, or an intestinal fistula We give cortisone and noradrenaline to patients with adrenal crises, and to those with diffuse peritonitis we give noradrenaline, cortisone, and electrolytes We have not yet found a remedy for the stricken heart, so to patients with coronary occlusion we give our sympathy

Shock will become irreversible if the blood fails in its primary object of bringing sufficient oxygen to the tissues This will occur if the anæsthetist fails to oxygenate his hypotensive patient, if the traumatic surgeon delays replacement transfusion until the constricted arterioles have strangled the tissues in their grip, or if the peritonitis is so severe and unresponsive to treatment that the poisoned blood-vessels can no longer be constricted by vasopressor agents

Lastly, sweating is an inconstant phenomenon of no diagnostic value Anyone who has danced a Paul Jones will concede the observation that some people sweat—and some don't

INTRAVASCULAR CLOTTING IN EXPERIMENTAL HÆMORRHAGIC SHOCK

SIR,—In 85 New Zealand rabbits significant changes in many clotting factors and in the overall blood-clotting mechanisms followed the removal of blood (40 ml per kg body-weight) rapid enough to induce reversible shock The phenomena observed could be divided in three major phases

During and in the first half-hour following hæmorrhage (*early phase*) the plasma-fibrinogen level, the serum-complement titre, and the labile-factor (factor-V) activity dropped rapidly On the other hand, the number of platelets doubled and the speed of formation and the total yield of plasma-thromboplastin were increased The latter finding was apparently due to the development of a potent accelerator of clotting, since the addition of serum from the animal in shock to a system in vitro containing normal platelets and normal plasma resulted in a much more rapid formation and increased yield of plasma-thromboplastin than when normal serum was used Also an experiment in vivo was devised in which normal rabbits received homologous thrombin-free serum from 50 ml of blood Only minor acceleration in the formation of plasma-thromboplastin followed when the serum was from normal animals The injection of serum from animals in hæmorrhagic shock, on the other hand, induced more rapid and complete formation of thromboplastin

As the shock deepened, even after arrest of bleeding and for as long as twelve to twenty-four hours afterwards, different findings developed (*late phase*) While the fibrinogen level continued to drop, platelets also became drastically reduced and the formation of thromboplastin was slow and incomplete

This phase was followed by a *period of recovery*, of two to three days' duration, during which all factors returned to normal. Histologic sections taken between the third and the seventy-second hour showed deposition of material with the morphological and staining properties of fibrin into some of the venous vessels of the lung, kidney, and liver

Analytical study of the fibrinolytic system suggested activation in vivo in the early phase because of considerable increase in the titre of antifibrinolysin and sharp decrease in the activity of profibrinolysin possibly consumed in vivo In the later phase, on the other hand, the serum profibrinolytic activity rose and that of antifibrinolysin decreased, suggesting a return of the fibrinolytic mechanism to normal

Splenectomy within three weeks before hæmorrhagic shock prevented most of the changes described or reduced their severity No clot accelerator developed in the splenectomised animals during the early phases of shock

Thus, significant intravascular clotting occurs in the early phase of hæmorrhagic shock. This statement is based on the findings of accelerated formation of thromboplastin because of the development of a clotting accelerator agent, appearance of thrombocytopenia, intravascular deposition of fibrin demonstrable by histologic techniques, and activation of the fibrinolytic mechanism Since changes were minor in splenectomised animals, the splenic contraction which accompanies severe hæmorrhage may initiate intravascular clotting through the immission into the blood-stream of tissular thromboplastin or of thromboplastic material from the platelets lysed within the splenic sinusoids

These results may have significant applications to human pathology A severe bleeding tendency characterised by fibrinogenopenia, thrombocytopenia, and exalted fibrinolysis has been observed during massive surgical bleeding [1] Earlier work suggested that the hæmostatic breakdown may be due in part to intravascular clotting The results of the present work support this hypothesis

Our investigation was supported by a grant-in-aid from the American Heart Association Essentially similar (unpublished) findings have been obtained in dogs at this laboratory by Leo Gagliardi, Hector Marin, and Mario Stefanini

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—May I suggest that much of the difference of opinion expressed in this correspondence is due to failure to distinguish the fundamental differences between a normal disc and a pathological one

The " disc material " one removes at operation, either for " disc prolapse " or " disc degeneration ", has physical properties entirely different from those of a normal disc. It is very similar to the abnormal disc material found in proximity to an early subepiphyseal tuberculous focus—i e., it is solid " stringy " material, aptly described as " crab meat " A normal nucleus pulposus is, of course, fluid—usually under considerable pressure If one compresses longitudinally two normal vertebræ and the intermediate disc, the bone collapses before the annulus ruptures Prolapse of a normal disc either never or hardly ever occurs It is only when the nucleus pulposus has lost its normal characteristics—probably through poor nutrition subsequent to ischæmia, secondary to infection or trauma—that prolapse of disc material takes place Examination of such material does not tell one the properties of normal nuclear fluid

AUTO-ANTIBODIES IN THYROID CARCINOMA

SIR,—The letter by Dr Stuart and Dr Allan (July 5), reporting the presence of high-titre thyroid auto-antibodies in 3 out of 6 cases of carcinoma of the thyroid, raises an important issue if serological tests are to be more widely used as an aid in the differential diagnosis between Hashimoto's disease and thyroid cancer Our experience in this connection may therefore be of interest

Thanks to the cooperation of Prof D Waldron Smithers and Dr N Howard, of the Royal Marsden Hospital, Mr B Truscott, of Addenbrooke's Hospital, Mr A S Till, of the Radcliffe Infirmary, and several others, and by studying patients in the Middlesex Hospital, we have been able to investigate serologically 36 cases of proved thyroid malignancy The sera were tested by the passive hæmagglutination of tanned cells coated with purified thyroglobulin, by complement fixation against thyrotoxic thyroid extract,[1] and by the precipitin reaction in agar The results are shown in fig 1 Auto-antibodies were found in 10 of the 36 cancer patients, the tanned-cell titres did not exceed 25,000 in our series and we have not so far obtained precipitins in a patient with thyroid cancer Only 4 of the 36 patients had complement-fixing antibodies

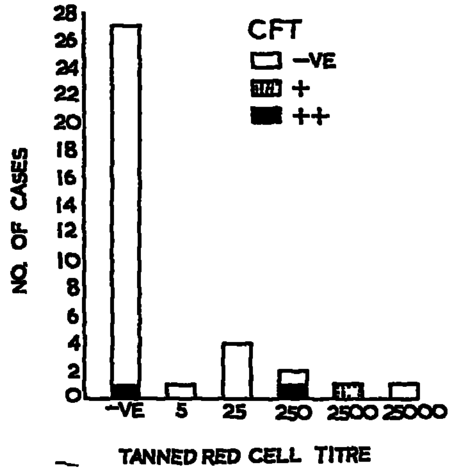

Fig 1—Thyroid auto-antibodies in cancer of the thyroid Tanned-cell hæmagglutination titres are expressed as the reciprocal of the highest serum dilution giving a one + agglutination. A single pipette was used for the serial dilutions of serum Complement fixation (CFT): +, complete inhibition of hæmolysis at serum dilution of 1/5, ++, complete inhibition of hæmolysis at dilution of 1/20 or higher

Of 44 cases of histologically proved Hashimoto's disease examined by the same series of tests (fig 2), all but 2 patients had circulating thyroid antibodies and 28 had levels sufficiently high to give precipitins Complement fixation was positive in all but 6 cases.

The presence of antibodies in the cancer cases probably reflects lymphadenoid changes surrounding the tumour, a known histological feature One would expect to find a high level of circulating antibodies where cancer is associated with widespread thyroiditis, as in the cases reported by Dr Stuart and Dr Allan In such cases, however, clinical features and other thyroid investigations often reveal the presence of a tumour In many cases the character of the swelling or the presence of secondary glands make the diagnosis obvious, while topographical survey of the ^{131}I uptake over the thyroid shows deficient or absent pick-up over the majority of malignant nodules Most Hashimoto goitres involve the entire gland, even when one lobe is larger than the other, and the iodine uptake is greater on the side of maximum swelling The B M R and serum-cholesterol may be of help since hypothyroidism is very uncommon in thyroid cancer and frequent in lymphadenoid goitre The rapid regression of Hashimoto goitres under thyroid medication is another feature of diagnostic value

---

[1] Trotter, W R., Belyavin, G, Wadhams, A. *Proc. R. Soc Med* 1957, 50, 961

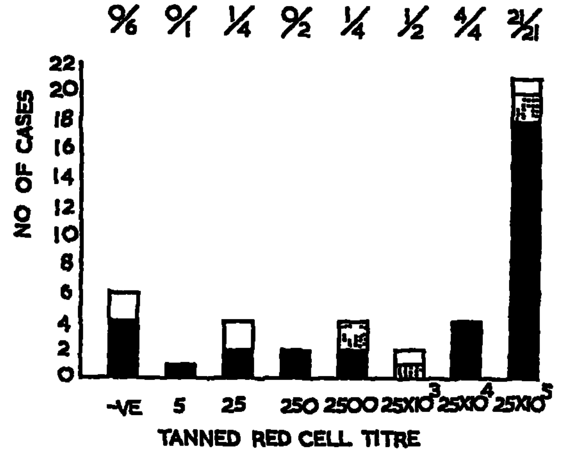

Fig 2—Thyroid auto-antibodies in histologically proved Hashimoto's disease Tests done before or within 3 weeks of operation Results are expressed as in fig 1 The proportion of patients having positive precipitins is shown above the appropriate column

We agree with Dr Stuart and Dr Allan that serological tests should be interpreted only in conjunction with careful clinical assessment and other available investigations, but only a more extensive study of goitre patients, especially those undergoing thyroidectomy, will show whether a differential diagnosis can be made with confidence on the basis of these combined criteria

ARTIFICIAL RESPIRATION

SIR,—In your annotation on this subject[1] you say

" *Even with intubation Safar et al did not succeed in moving more than 700–260 c.cm of air with either the Holger-Nielsen or the Silvester method This is far below the ventilation regularly attained in the investigation of Gordon et al, but the reason for this difference is not clear* "

When a tracheal tube was in place, we moved with the Holger-Nielsen method in 5 curarised subjects tidal volumes of 260–840 c.cm (average 655 c cm)—the small tidal volumes in obese subjects, the large tidal volumes in lean subjects Our subjects were lying on a hard table Gordon moved approximately 1000 c cm per breath in tall, lean, and healthy volunteers, who were lying on the floor Our small tidal volumes are easily explained by the reduced chest distensibility, since some of our subjects were heavy and short Our large tidal volumes are smaller than Gordon's because our subjects were lying on a table The small tidal volumes are not surprising in view of the findings of other investigators—namely Nims et al,[2] Waters and Bennett[3]—who could move only 140–280 c cm per breath with these push-pull methods and with a tracheal tube in place, they studied apnœic patients who were obese or whose lung-chest distensibility was reduced by disease

Without tracheal tube 11 of 15 subjects (lying on the floor) could not be ventilated with the Holger-Nielsen method, because of upper airway obstruction This was confirmed recently by Gordon et al,[4] who were unable to ventilate 40–50% of the curarised subjects studied when they did not use a tracheal tube

We learned from a separate study of unconscious patients who were not curarised that pharyngeal obstruction by the tongue due to flexion of the neck and sagging of the mandible is at least as common in the prone as in the supine position, even when an artificial oropharyngeal airway is in place The Esmarch-Heiberg manœuvre (extension of the neck plus forward displacement of the mandible) seems to be the single most important point in respiratory resuscitation

You remark on successes known to have followed use of the Holger-Nielsen and Silvester methods But who knows whether an asphyxia victim in the field survives in spite of or because of the method applied? Many comatose asphyxiated patients have been awakened by external stimuli only Airway obstruction is unpredictable There is no doubt that occasionally the airway is open during performance of the push-pull methods, but the rescuer is unable to recognise movement of air while working on the patient's chest

You suggest that dizziness may affect the operator while performing mouth-to-mouth breathing We confirmed Elam's data[5]

The rescuer could perform mouth-to-mouth breathing for 30 minutes or longer without becoming dizzy Whenever he felt dizzy he automatically reduced the rate of inflations, and levelled off at an end-expiratory carbon-dioxide level of 3–4%, while that of the subject was 4–5% The oxygen saturation and the end-expiratory carbon-dioxide level in the subject were maintained at normal levels with tidal volumes at least twice as large as normal at a rate of 10 inflations per minute or more The restricting factor in prolonged mouth-to-mouth breathing is not dizziness of the operator, but fatigue of his back and hands

A motion picture on *Respiratory Resuscitation Techniques*, which was made during one of our experiments, shows the experimental techniques and results better than a paper The motion picture may be borrowed from Army Medical Institute of Research, MAVD, Walter Reed Hospital, Washington, D C (Attention Sergeant H Dixon)

OOPHORECTOMY AND BREAST CANCER

SIR,—Your leader of July 12 refers in passing to the variable persistence of œstrogen excretion following bilateral oophorectomy and adrenalectomy for breast cancer

I think it worth calling attention to a simple and practical possibility that may repay exploration, before some mysterious third source of œstrogens is postulated or sought—namely, the ovarian hilus cells These (which resemble Leydig cells and are invariably present) are found throughout the mesovarium, and extend medially along the ovarian ligament. The recent monograph of Morris and Scully[1] gives an account of them together with evidence that they can produce œstrogen; an earlier review is that of Sternberg.[2]

---

[1] *Lancet*, 1958, i, 1322.

[2] Nims, R. G Conner E H, Botelho, S Y, Comroe, J H, Jr *J appl Physiol* 1951, 4, 486

[3] Waters, R M, Bennett, J H *Anesth Analg* 1936 15, 151

[4] Gordon, A S, Frye, C W, Gittelson, L, Sadove, M S, Beattie, E J, Jr *J Amer med Ass* 1958, 167, 320

[5] Elam, J O, Brown, E S, Elder, J D, Jr *New Engl J Med* 1954, 250, 749

Experience shows that oophorectomies for breast cancer vary: sometimes the operator seems bent on removing nothing whatever except the ovary, whilst at other times a generous slice of mesovarium is included. This may account for the variations noted. It seems clear that as much mesovarium and ovarian ligament as possible ought to be removed, and a tentative case might be made for bilateral removal of the adnexa.

London, W.C.1 P. E. HUGHESDON

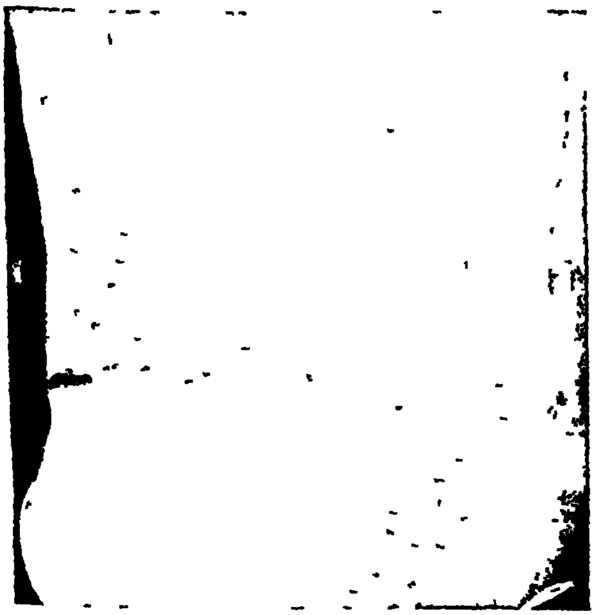
SKIN REACTION INHIBITED BY X-RAY THERAPY

SIR,—The following case is reported in the hope that some useful explanation may be obtained.

A man, aged 63 years, was admitted with a history of four months' pain in the left buttock. X-ray examination showed a large osteolytic lesion in the right ilium, which was diagnosed as a secondary deposit from a carcinoma of the prostate. The gland was enlarged, hard and irregular. The patient complained of moderately severe pain in the buttock three minutes after the intravenous injection of 250 mg. of stilbœstrol diphosphate ('Honvan'). There were no other positive findings.

On April 14, 1958, he started on a palliative course of deep X-ray therapy (190kV 300r daily skin dose to a field 20 cm. × 15 cm.). He had no treatment on April 19 and 20. On April 21 he awoke with a patchy macular rash on his trunk, thighs, and arms. There were also a few spots on his forearms and legs. The area being treated by X rays was completely clear and showed no evidence of the rash or of radiation erythema. The borders of the treated area were fairly sharply demarcated; if anything, the unaffected region tended to spread outside the blue lines used to delineate the area for treatment. Owing to the curvature of the buttock some of the radiation was likely to fall outside the prescribed rectangle, particularly at its medial and lateral sides.

The accompanying photograph was taken on April 22, by which time there was a faint suggestion of erythema in the irradiated area but certainly no blotchy rash. The patient was then given antihistamine drugs, and the X-ray therapy continued. The rash disappeared the next day. The cause of the rash is unknown. Perhaps it was due to an aspirin tablet he took the day before, perhaps to an enema.



A presumably allergic reaction seems to have been inhibited by a dose of 1500r in five days, and this inhibition occurred before any skin response to irradiation could be seen.

SHOULD BIBLIOGRAPHIES GIVE TITLES OF PAPERS?

SIR,—I should like to add my plea to Mr. Patey's (July 19) that bibliographies should include titles of papers. This is particularly important in review articles.[1] The references are quoted with more care, the bibliography itself makes interesting reading. These and other advantages easily compensate for the exclusion of a short article.

With too much to read, I value quality before quantity.

NON-ADRENAL FEMALE PSEUDO-HERMAPHRODITISM ASSOCIATED WITH HORMONE ADMINISTRATION IN PREGNANCY

SIR,—Attention has recently been drawn to the occurrence of partial virilism in female infants when the mother has received hormonal treatment during the pregnancy for repeated miscarriages or hæmorrhage during pregnancy. Lawson Wilkins and his colleagues[2] from the Johns Hopkins Hospital have collected 18 instances of this condition as well as 3 exactly similar in which the mother had received no hormones. Other instances have been reported by Hayles and Nolan[3] and by Nellhaus.[4] Wilkins has made a plea for smaller dosage of steroids and for the deferment of treatment until after the tenth week of pregnancy.

My colleagues and I at The Hospital for Sick Children, Great Ormond Street, have seen 3 such babies in the past year or so. They will be more fully reported elsewhere (with due acknowledgment to all who have contributed), but as the degree of masculinisation appears clearly in these to be related to the intensity and date of starting treatment they are briefly reported here.

CASE 1.—Aged just over three years on admission, this child, registered as a male, had a phallus with a urethral opening beneath it, and a scrotal-like structure with a median raphe but no testicles. Investigations excluded adrenal abnormality, and female sex was indicated by the nuclear chromatin in the white blood-cells. Laparotomy showed a normal uterus, fallopian tubes, and ovaries but absence of a vagina. In view of repeated miscarriages the mother had been given (as soon as she was known to be pregnant) tablets containing ethinylœstradiol 0.01 mg. and methyltestosterone 3 mg. twice daily for one month and three times daily for two months. She also had an implant of progesterone (50 mg.) in the third month and again in the fourth month of pregnancy.

CASE 2.—Aged nine days on admission, this child, of whom the sex had been considered doubtful at birth, showed an enlarged clitoris with a urethral opening on its under surface, and fused labia with a small vaginal orifice. There was no evidence of adrenal abnormality. Female sex was established by the nuclear chromatin of the white blood-cells. Examination under anæsthesia showed a wide vagina and normal cervix.

[4] Nellhaus, G. *New Engl. J. Med.* 1958, 258, 935.

From the sixth week of pregnancy the mother had taken six tablets a day containing 0 01 mg of ethinyloestradiol and 10 mg of ethisterone until she was delivered by cæsarean section at the thirty-eighth week

CASE 3 —This child, admitted at the age of four weeks, was noted to have a large clitoris at birth, confirmed on admission Examination showed the presence of a vagina and a small uterus, the ovaries were probably felt There was no evidence of adrenal abnormality and female sex was confirmed by the nuclear chromatin in the white blood-cells The mother had received tablets of methyltestosterone 10 mg three times a day for three weeks about the third month of pregnancy for vaginal bleeding and again at about the sixth month for about six weeks for the same reason Seen at one year of age this child showed a clitoris only slightly larger than normal

These three cases have been set out in order of severity In case 1 the mother received the earliest and most intensive treatment, but even in case 3 the mother was not treated until the third month It may be, as Lawson Wilkins and his colleagues remark, that these children might not have been born at all but for the treatment, but in view of the psychological and other problems presented they appear to support the plea for not starting it too early and keeping the dosage as low as possible

ALAN MONCRIEFF

PS—Since submitting this letter, I have read an annotation in the *British Medical Journal* (July 26, p 218) which suggests postponing hormone treatment until after the fourth month —A M

INTERFERENCE WITH TELEVISION

SIR,—*I happen to live in the vicinity of Harley Street* and to possess a television set The only time I *try* to look in in the afternoon is when show jumping and Wimbledon are on It is quite impossible to ask anyone to share this pleasure with me because some selfish doctor or nursing-home turns on a machine without a suppressor, which, apart from causing a tremendous roar, completely obliterates the picture The Post Office say that they cannot force anyone to add a suppressor (which I believe costs half-a-crown) and that they have more complaints from around here than in any other area

London, W 1

ENID DOUGLAS DERRICK

HÆMOPHILIA-LIKE STATES IN GIRLS

SIR,—Professor Quick and Miss Hussey,[1] when they discuss hæmophilia-like states in girls, have omitted mention of the cases of hæmophilia in human females which occurred in the family originally described by Treves[2] and subsequently by Bulloch and Fildes,[3] by Handley and Nussbrecher,[4] and by myself[5] One does not expect authors to review the whole of the published literature each time they write a case-report, but this family is unique in two ways Firstly, the family studies extend over a very long period, and secondly, this family is probably the first in whom the diagnosis of hæmophilia was established in females with any degree of certainty Quick and Hussey are clearly aware of these reports since they mention them in other publications[6 7]

They have objected to the diagnosis of hæmophilia because of the alleged male-to-male inheritance in the first four generations and also because hæmophilia-like disease was not excluded Their first objection I have already discussed in detail[5] It is no longer possible to prove or disprove this inheritance since the patients all died very many years ago, the history of bleeding in them is very scanty and often amounted to no more than a tradition in the family that they were bleeders The inheritance in recent years is typical of hæmophilia

Their second objection was possible but improbable Blood of hæmophiliacs from 3 different families was used in testing this family It was possible to deduce the fact that at least 2 hæmophiliacs with different clotting-times were used[5], they were consequently probably unrelated The fact that 3 unrelated hæmophiliacs were used did not appear to be important at the time and so was not mentioned These three hæmophiliacs are now known to have classical hæmophilia It would be unlikely that an error in the diagnosis of hæmophilia would have been made in all these cases In any case the matter has been put beyond doubt by the statement of Taylor and Biggs[8] that later work has shown that the family described in my paper have classical hæmophilia

PREVENTION OF POSTOPERATIVE TETANUS

SIR,—Professor Pannett[9] criticised the use of the tourniquet in limb operations, a routine which he regards as a harmful and backward step in surgery He quotes two unjustifiable risks associated with the use of a tourniquet (1) damage to nerves and muscles, and (2) lowering of tissue resistance to infection At the time his letter was published a married woman, aged 39, died in Melbourne from tetanus contracted during an operation of election—namely, a meniscectomy—in which a tourniquet was used This case and its circumstances are pertinent to Professor Pannett's letter and to your editorial comments[10 11] on the importance of efficient ventilation in operating-theatres

The infection was a fulminating one and death occurred three days after a short incubation period of five days *Clostridium tetani* and *Cl sporogenes* were isolated at necropsy, and during life from fluid inside the knee-joint and from the surrounding tissues The sterilisation of the instruments, textiles, dressings, talc, &c, was carried out efficiently with tested equipment The operating-theatre and sterilising annexe were connected by a sliding door which is kept open during the setting-up for an operation and both rooms were ventilated by means of exhaust fans placed in large ducts opening in the ceiling These ducts were protected by a wide-mesh wire guard and could not be cleaned except by unscrewing the guard As might be expected, they were heavily laden with dust Cultures from the dust in each yielded various species of clostridia, including a non-toxigenic strain of *Cl tetani*

When the fan in the sterilising annexe is operating, air is sucked into the theatre through its dust-laden duct or from the corridor, and vice versa When the fans are not operating air currents set up by external wind or by convection pass along the ducts providing a further opportunity for dislodging dust Since the sterilisation was adequate it can only be assumed that this infection developed from dust contamination of the wound or the instruments during the operation To what extent the use of a tourniquet and a tight bandaging of the wound thereafter contributed to tissue anærobiosis is difficult to say However, this case raises several interesting points

In the past five years in Victoria there have been 56 notified cases of tetanus, of which 6 (about 11%) followed operations of election Of these 6 cases, 3 were operations on the knee or ankle joints Sevitt[12] reported 2 hospital-infected cases, both involving operations on the leg, and he also described[13] a case of gas gangrene after an operation on the ankle Of the 4 postoperative tetanus deaths in England and Wales in 1954 2 followed operations on the foot[14] Since such operations must constitute only a small fraction of the total surgical load they seem to carry an unexpectedly high risk of tetanus In contrast to the present trend, Wainwright[15] reported, from a survey of tetanus over twenty years, that, while postoperative tetanus accounted for 10% of civilian cases, 70% followed gynæcological and abdominal operations

Although postoperative tetanus is an uncommon disease, the case-fatality rate is high (about 44% in Australia)[16] In its elimination as a surgical hazard, four levels of prevention, two general and two specific, can be considered

The first is the intelligent use of efficient sterilisation equipment recommended by Bowie,[17] a factor which does not require comment here

The second is concerned with effective ventilation of operating suites using filtered air and a plenum system, based on the principles described by Bourdillon and Colebrook[18] and more recently by Blowers[19]

The third lies in the more conservative use of tourniquets, as suggested by Professor Pannett

The fourth is to immunise patients with tetanus toxoid before all elective operations of the lower limbs in which tourniquets are used, particularly those involving the knee or ankle joint If the patient has not been actively immunised, two injections, one four weeks before and another at the time of operation, would not seriously interfere with the management of a case The individual who has been actively immunised may be given a preoperative booster injection of toxoid In emergency operations of the type being discussed prophylactic antitetanus serum followed by active immunisation during convalescence would be a useful safeguard

While dealing with the subject of selective immunisation in non-traumatic surgery it might be suggested, on the analogy of passive transfer of immunity in diphtheria,[20] that neonatal tetanus, which accounted for 4 9% of cases in an Australian series[16] and 3 4% of deaths from tetanus in England,[21] could be abolished by active immunisation of the mother during pregnancy

Finally, as more individuals are now being actively immunised against tetanus[22] a clear distinction should be drawn *for the patient* between active and passive immunisation We recommend that individuals who are given tetanus toxoid be informed, verbally and perhaps in writing, that the immunisation was a "T T injection" and when antitoxin is used it is always referred to as an "A T S injection"

CHARGES FOR NIGHT CALLS

SIR,—In your leading article of July 5, you described the National Health Service as simply a legislative device by which doctors can continue their work without charging fees, and this was the most attractive part of it to most doctors whether they actually approved of the service or not But after a very short time, the Socialist Government which had sponsored this free service put a charge on drugs and appliances as a deterrent, and I think that was quite wrong The collection of these charges must have caused considerable misgivings to chemists and opticians and others who had to collect this payment from some patients who could ill afford it

Dr Guy Dain, who always expressed himself as being wholeheartedly in favour of a comprehensive medical service available to 100% of the population, has now suggested[1] that "it would probably remove some disgruntlement if the doctor could make a charge (to be fixed) for late and night calls for visits" What amount would Dr Dain suggest, I wonder, as the fee for a late call and for a night call? Is the same fee to be applicable to all classes, irrespective of their income group and irrespective of whether they are old-age pensioners? Is the fee to be retained by the practitioner himself, or will he be merely collecting it on behalf of the Treasury, in view of the fact that this charge, like the charges on prescriptions and appliances, is intended as a deterrent

Many doctors working in the service today have never worked in the times when doctors charged fees to patients, and probably have no desire to do so now I think it would cause considerable embarrassment to a young doctor if he had to demand a fee from a patient who had been taken ill in the night, or even from anxious relatives If, from time to time, additional fees are to be charged to patients in order to deter them from using the National Health Service, it makes a nonsense of the whole scheme, and it would be better to return to the old system where patients made their own arrangements

LESLIE HARTLEY

THE DAY HOSPITAL

SIR,—The excellent article by Dr Craft (July 19) on the treatment of depressive illness at the Maudsley Hospital shows a higher rate of recovery in patients treated in the day hospital than those treated in the adjoining inpatient hospital The investigation would have been even more useful, however, if it had been undertaken as a piece of interdisciplinary operational research including the contributions of a sociologist and a cost accountant

Mental illness involves interpersonal relationships at home and at work There is less disturbance of family relationships when the patient still lives at home than when he goes into hospital, and this may well contribute to increased speed of recovery Again, he will probably find it easier to resume work or obtain a new job if he has been attending a day hospital than if he has been an inpatient, but as yet these points have not been compared sociologically

Equally important is the economic aspect of day hospitals, where comparable medical care can be given at a substantially lower cost than in an ordinary hospital It is regrettable that in the most recent Ministry publication on hospital costing there is no breakdown of the comparative costs of care of Maudsley Hospital inpatients and those in the adjoining day hospital The comparison may well be difficult, but this is the type of problem that is dealt with daily by industrial cost accountants

In the years to come, day hospitals will probably have an increasingly important role in the treatment of non-catastrophic illness, and their development may well influence the whole concept of hospital design and medical care in urban areas Such changes can be justified only by comprehensive research which, under present financial conditions, can most easily be undertaken by teaching hospitals, and must include the social and economic needs of the family and of the community

ORAL TREATMENT OF PERNICIOUS ANÆMIA

SIR,—I should like to comment upon some aspects of the challenging article by Dr Heathcote and Dr Mooney[1] They state that they have isolated a vitamin-B_{12}-peptide from a streptomyces fermentation "shown clinically to be the most effective oral preparation yet available" for the treatment of pernicious anæmia The "failure of simple proteolysis in the stomach" to which they refer, seems unlikely to be of ætiological importance in that disease, but a vitamin-B_{12}-peptide might well be physiologically significant in the transport of vitamin B_{12} across the intestinal wall Consequently it is disappointing to find that the authors have submitted no convincing evidence that their vitamin-B_{12}-peptide was more active hæmatopoietically than its content of vitamin B_{12}

Thus, as pointed out by Dr Latner,[2] the high vitamin-B_{12} content alone (100 µg) of the peptide given daily during the initial stage of the therapy of each patient may have produced the remissions noted Failure to relapse thereafter during a few months of reduced maintenance therapy is notoriously poor evidence of therapeutic activity Even if Dr Heathcote and Dr Mooney's claim for the therapeutic efficacy of their vitamin-B_{12}-peptide is accepted, the conclusion that "intrinsic factor does not exist" seems irrelevant

In their reply[3] to Dr Latner's letter, Dr Heathcote and Dr Mooney express lack of confidence in the interpretation of "short-term responses" If by that phrase they refer to carefully controlled observations upon serial reticulocyte responses during successive 10 to 14 day periods of uniform daily therapy in individual patients, it may be of more than historical interest to point out that it was in large part with the aid of such a clinical index that therapeutically effective liver extracts were originally developed and that the clinical activity of vitamin B_{12} itself received final confirmation Indeed, by such methods the activity of the so-called gastric intrinsic factor was first demonstrated Since then its more convenient assay by comparative observations upon the assimilation by individual patients of small single doses of radioactive vitamin B_{12}, first without and then with intrinsic factor, has become an established practice

In my opinion, until such comparisons in the same patient are appropriately applied to the present problem, first employing single doses of not more than 5 µg of vitamin B_{12} alone, the alleged superior hæmatopoietic activity in pernicious anæmia of the vitamin-B_{12}-peptide over that of its content of vitamin B_{12} will remain uncertain

RADIOGRAPHERS IN THE N H S

SIR,—Since you wrote on this subject, over a year ago,[4] the shortage of radiographers appears to have increased steadily, with little further mention of the fact in print Medical staff of hospitals where the radiological service is necessarily drastically reduced are naturally asking what is being done and what are the prospects of restoring a proper service

As there is a limit to what can be done by the heroic devotion of radiographers, the understaffed departments are faced with the unavoidable choice of foregoing the less urgent types of examination (and who is to decide which are these?) or of employing unqualified personnel

A somewhat similar situation during the war was met by the Services training their own radiographers to an acceptable minimal standard, and I fear that stark necessity may shortly force some hospitals and chest clinics to train local labour to undertake the simpler radiographic examinations by rule-of-thumb methods Once started, such a practice would be difficult to stop, and it might well lead to degrading of radiographic standards generally unless arranged under the direction of the Society of Radiographers

Understaffed X-ray departments would welcome an authoritative statement about the present and future position of radiography

J A BROCKLEBANK

DURATION OF PREGNANCY

SIR,—The duration of pregnancy, measured in days or lunar months, varies considerably from one "normal" baby to another, and so prediction of the date of birth is subject to error even in normal pregnancies The average length of gestation is accurately known to apply this to an individual case, some correction is required for the "time-scale" of the particular mother and child The late Dr W E Dickes Rost suggested in her unpublished notebooks that the required correction might be made by substituting the length of the mother's periods for the lunar month, as the unit of time It was hoped that calculation of the expected length of pregnancy as ten times the length of the mother's periods would be more accurate than the present system It has already been reported that the incidence of abortion shows peaks at intervals of about 4½ weeks[1]

FLAMMABLE CLOTHING

SIR,—I can fully appreciate the disappointment expressed by Mr Willby (July 26, p 217), press officer to the British Standards Institution, at the discussion on flammable clothing at the meeting of the British Medical Association in Birmingham, for it is quite possible that many of the speakers confused the B S I with the British Government Many of us who work in burns centres are dissatisfied not so much with the B S I, which does very good work within its very definite limitations, but rather with a Government which, in spite of the recommendations made in the B S I report, has done virtually nothing to popularise the existence of attractive flame-resistant clothing fabrics or to encourage their manufacture and sale at a reasonable price, even though this might require a special, though probably only temporary, Government subsidy, as recommended by Colebrook et al[2]

Experience in South Wales over the past two and a half years has shown that many big departmental stores or shops still refuse to stock flame-resistant fabrics some may have the fabrics in stock, but will not display them because of their high price Even more staggering are the popular misconceptions held by directors, buyers, and departmental managers, let alone the sales staff, about the relative flammability or safety of different fabrics It is thus very distressing to find that a good deal of one's personal effort and that of the various home-safety committees in encouraging parents to ask for flame-resistant fabrics is wasted by apathy or ignorance in the retail trade

J A BOYCOTT

Parliament

Children's Bill

THIS Bill [1] includes a provision that in considering whether to make an adoption the court shall have regard "to the health of the applicant" At the report stage on July 25 in the House of Commons, to this provision were added the words "as evidenced, in such cases as may be prescribed, by the certificate of a fully registered medical practitioner" Some members regretted that the amendment did not go further and make medical testimony compulsory Miss PATRICIA HORNSBY-SMITH, parliamentary secretary to the Home Office, gave an assurance that the Lord Chancellor intended to make rules requiring a medical certificate in most cases But he did intend to except some cases, when, for instance, the applicant was the mother of the child

The Bill was read a third time

QUESTION TIME

Suicides and Attempted Suicides

Mr KENNETH ROBINSON asked the Home Secretary if he had yet reached a conclusion on the desirability of amending the law relating to suicide and attempted suicide —Mr R A BUTLER replied No, Sir My study of this question suggests that in its practical aspects the problem is largely one of ensuring that those who need care or treatment to prevent them from endangering themselves or others in fact receive it In general, where this can be done without the intervention of the courts proceedings are not taken, but there is a residue of cases in which the person concerned cannot be given or will not accept, care or treatment without the intervention of the courts I shall continue to study this aspect of the matter and I am in consultation with the Minister of Health

Mr ROBINSON Is not the Minister taking rather a long time to reach a conclusion on a matter where the overwhelming weight of opinion is in the direction of reform? If the Government are not prepared to take the initiative in this matter, can he say what would be their attitude towards the initiative being taken by a private Member?—Mr BUTLER I cannot state what my attitude would be towards the initiative of a private Member until I know the nature of that initiative. I do not know whether the hon Member is aware that the joint committee of the British Medical Association and the Magistrates' Association has commended the law and practice in Scotland in this matter The reason I am not going any further in answer to the hon. Gentleman is that we are at present carefully considering that with a view to seeing what we might do about it

Mr CHARLES ROYLE Will not the Minister hold out a little more hope in this matter, particularly as involved and responsible organisations are taking the view that they are? Cannot we get more in line with other countries who never regard attempted suicide as a criminal matter?—Mr BUTLER It so happens that in 1956, the last year for which I have figures, proceedings were taken in 613 cases of attempted suicide out of a total of over 5000, and only 6 7% of these proceedings resulted in sentences of imprisonment, and there is a certain limit to that But I am considering the whole question

More Dentists

The Ministry of Health, after consultation with the University Grants Committee, have accepted the recommendation of the McNair Committee that the annual output of dental schools in Great Britain needs to be expanded to produce at least 800 dentists who will practise in this country To allow for wastage and students from overseas the schools' present potential intake of about 650 students per annum in their first professional year must be expanded to something over 900 places The Ministers aim to start expansion as soon as possible, and, when considering projects for inclusion in the Government's programme for major hospital building schemes, they will give due regard in consultation with the University Grants Committee, to proposals which will contribute to it.

Working Party on Hospital Medical Staffing

Mr ARTHUR BLENKINSOP asked the Minister of Health how many of the members appointed by himself and the Secretary of State for Scotland to the working party on medical staffing of hospitals had experience of the staffing problems of any other than teaching hospitals —Mr R. THOMPSON replied All 6 2 are currently serving in non-teaching hospitals, the other 4 are concerned in the health departments with the staffing problems of the hospital service as a whole

Smoke Control

The Minister of Housing and Local Government has confirmed 34 orders establishing smoke-control areas 13 orders are under consideration and a further 102 orders have been provisionally notified to him by local authorities

GEORGE MACFEAT WISHART

M D, B Sc Glasg, F R F P S

George Wishart gave Glasgow University forty years of effective and varied service as scientist, teacher, and administrator He retired in 1947 from the chair of applied physiology to preside over the faculty of medicine, and the only flaw in his colleagues' and students' admiration for the dean was regret at the loss of the professor

His father was a Glasgow grain merchant and he was educated at Uddingston Grammar School and the University of Glasgow, where he graduated B SC and M B in 1918 After serving a year with the R A F medical service he returned to the university as an assistant in the institute of physiology Two years later he was appointed to the Grieve lectureship in physiological chemistry He found time for postgraduate study in Sweden and Germany, and, nearer home, he spent several vacations working at the Hannah Dairy Research Institute during its early formative years Much of the research of these early years was summarised in his authoritative M D treatise on basal metabolism, for which he was awarded the Bellahouston medal in 1926, and in his *Groundwork of Biophysics* which was published in 1931

In 1935 Wishart was appointed to the Gardiner chair of physiological chemistry As a teacher he was “ almost deceptively good ”, as the Principal of the university put it in his tribute last week

“ Neither in the lecture-theatre nor elsewhere was he anything of an orator But his words were so beautifully ordered that only when his students came to work over his material for themselves did they discover how difficult were some of these apparently simple ideas In the laboratory he had swift curiosity, ingenious mind, and contriving hands, happily employed in the experimental work of the school on the borderland of the natural and the biological sciences ”

In 1947 the faculty of medicine was faced with new duties and wider responsibilities, the new health service was to alter the administration of the teaching hospitals, and the opportunities for postgraduate education were to be extended The faculty felt the need for the support and counsel of a full-time dean, and Wishart was their unanimous choice He accordingly resigned his chair to take up his new appointment, to which he added the additional charges of directorship of postgraduate medical education in Glasgow and membership of the General Medical Council Of his bearing and achievements in this new career J W H writes

“ George Wishart set himself a programme of work which would have been beyond most men's will and energy As Dean of the faculty, his leadership was truly that which aspired above all to serve *His colleagues know how well he served* Faculty meetings kept to the point and did not drag on until exhaustion produced resigned assent or snap decisions On the contrary, the Dean saw to it that he was well prepared beforehand He not only knew the business; he knew also what was likely to be said for and against any proposition, and he knew pretty well who would be saying what If he foresaw trouble, he would arrange for quiet consultations beforehand Thus, business came to the faculty well considered The issues were not cut and dried, but there were few surprises for the Dean. Even the most difficult matters were usually settled quickly and amicably, and if it emerged that this would not happen he was ever ready and keen to take the matter away for further study—which meant that he put in even more hard work and consulted still more of those whose interest was involved The meetings went quickly and smoothly not because he avoided discussion, but because he provided the work which kept the discussion informed and made the opportunities for all whose concern was serious to give their minds to the problem in advance Each year, the faculty required less than ten seconds to re-elect him dean after he and the clerk had withdrawn, this was only one of the measures of the confidence and gratitude of his colleagues

“ He was ever careful of the best interests of the students —the mediocre and the disappointing as well as the industrious and brilliant Many of the students from overseas owed him a particular debt, and he was much gratified when one Nigerian named his villa after him and sent him a photograph showing the name clearly marked in big letters on the gateposts It was a well-conceived gesture, for Wishart was always keen to see people get what they desired if he thought that they had a good or even a fairly good claim Unduly high rates of failure in the examinations always disturbed him, and the last explanation of these that he would ever accept was that the students were a poor lot Even if all his colleagues did not accept some of his alternative propositions, they admired and respected his faith in the students and his advocacy of their case

“ He directed postgraduate education in Glasgow with great care and thought He never allowed schemes to become grandiose or to flourish merely because they looked wonderful on paper He was ever aware of the need to keep education medical and realistic as well as to have it scientific and polished He admired high standards but he was critical of claims that overreached realities Teachers who had something real to offer could always count on his welcome and his protection, especially if their position might have made them liable to be overlooked

“ On the Regional Hospital Board he gave hours of devoted service, taking scrupulous care over the anxious matter of all appointments, including the most junior Wishart was anxious to support the right cause and to do it for the right reason His fairmindedness made him an ally worth having in any debate or administrative battle Every now and then he would telephone and say ‘ Listen now—don't explode—just listen and tell me how you think this one would go ’ ‘ This one ’ often proved to be a bureaucratic proposal that would be bound to rouse righteous professional indignation ‘All right,’ Wishart would say, ‘ keep calm, don't worry, I think I know now what to tell them That's all I wanted ’ And so many potential wrangles were happily averted by his quiet watchfulness over professional interests and by the good name he made among administrators for his fairminded advice

“ His colleagues know that they will miss his service and his leadership, they have still to discover how great their loss is ”

This later absorption in administration tended to divert attention from the merit of his earlier research In assessing this work R C G writes

“ A generation or so ago medicine was still very much an empirical art Many medical men viewed askance the disturbing intrusion of chemistry and of physics into the preclinical discipline of physiology with its lusty offspring biochemistry Wishart, on the other hand, was instinctively at home in the physical sciences—in chemistry, in physics, and in mathematics It was very much his pleasure to apply physical techniques to the solution of biological problems His studies with Thunberg in Lund gave him a continuing interest in biological oxidations and reductions and in the conditions governing enzyme action. He also did some work on the metabolic products of muscular activity; he designed a glass electrode for measurements of pH.

"Perhaps the biophysical approach appealed rather more than the biochemical approach. In the '20s the impact of electronics on biology was just developing, everyone built a wireless receiving set. But Wishart turned this new hobby to good account in the laboratory, with an electronic oscillometer he made most valuable measurements of the blood-pressure in different parts of the human body. Quite a different style of gadget, but still showing the flair for the physical approach, was a pursuit meter, useful both in physiology and in psychology, and well in advance of contemporary design.

"However, indirect calorimetry was Wishart's real love. There was no longer any doubt about the validity of the technique, but a whole host of biological problems clamoured for attention. The actual amount of the energy expended by human beings in different tasks under various conditions offered a wellnigh inexhaustible reservoir of topics for research. In the laboratory he helped to design and build a walking platform and a bicycle and other types of ergometer. The mechanical efficiency of the human muscular machine was a somewhat more academic problem, and the validity and usefulness of the conception of a basal metabolic rate was, and still is, both an academic and practical issue.

"All Wishart's scientific work had an elegance born of meticulous care and scrupulous precision. To this was added a fastidious dislike of loose assumptions, uncritical argument, and anything which smacked of self-advertisement. The work he did for his university and for the medical services was at the expense of scientific work of the highest calibre: one can well regret the scientist lost in the administrator."

Professor Wishart died on July 18. He leaves a widow, who was one of his colleagues in his department, and two daughters one of whom is a doctor.

KEITH CHITTY

M.B. Camb., F.R.C.S.

Mr. Chitty, who was appointed consultant surgeon to the Mid-Worcestershire group of hospitals last December, died at his home in Chaddesley Corbett, near Kidderminster, on July 9, at the age of 38.

He was the son of Mr. Hubert Chitty, consulting surgeon to the Bristol Royal Infirmary, who survives him. He was educated at Clifton College, and gained an exhibition at Peterhouse, Cambridge, in 1938. From there he went to University College Hospital, where he won the Erichsen prize in practical surgery. He qualified in 1943, and soon afterwards joined the R.A.M.C. He landed in Normandy on D-1 and was medical officer to the engineers who constructed Mulberry Harbour. He served throughout the campaign and later went to India. After his return in 1947, he spent five years as a registrar at U.C.H., serving successively under Prof. R. S. Pilcher, Mr. Cecil Flemming, and Mr. H. R. I. Wolfe. In 1952 he went to the United Bristol Hospitals, and he held the post of senior registrar to the genitourinary department until 1955, when he became senior surgical registrar at the Bristol Royal Infirmary and the Children's Hospital.

W. M. C. writes:

Keith had served a long and arduous apprenticeship in making himself an accurate and efficient surgeon. He never pushed himself forward, but he was beloved by us all for his forthright and diligent approach to his work, and his unassuming competence made him the best of colleagues. He never blamed anybody else if things went wrong, and no night was too long or operating-list too heavy for his enthusiastic willingness to give everything he had got to serve his patients. His colleagues at Kidderminster quickly accepted him as an efficient and reliable surgeon, and he was welcomed there both professionally and socially.

Mr. Chitty leaves a widow.

Notes and News

ASME

THE first conference of the Association for the Study of Medical Education[1] will be held at the Royal College of Physicians of London, Pall Mall East, S.W.1, on Thursday and Friday, Sept. 25 and 26. The theme chosen for the meeting is Experiment in Medical Education.

Prof. Robert Platt, P.R.C.P., will take the chair at the opening session when Sir Russell Brain will give an inaugural address. Other speakers will include Dr. G. P. Berry (Harvard University), Sir George Pickering, Dr. Nicholas Malleson, Prof. G. M. Bull, Dr. J. N. Morris, Prof. T. Hale Ham (Western Reserve University), and Prof. B. Rexed (Uppsala University).

The conference is open to members of the association and others, and applications should be sent to Dr. John Ellis, the hon. secretary, at the college. Further particulars will be found in our advertisement columns for July 19 (p. 38).

BRUCELLOSIS

THE third report of the F.A.O./W.H.O. Expert Committee on Brucellosis,[2] drawn up at a meeting in Lima, Peru, in October, 1957, witnesses to the continuing great importance of brucella infection of animals and man in many countries of both hemispheres, but it also records important advances in the prevention and control of such infections, particularly in regard to bovine brucellosis (contagious abortion) in the United Kingdom, the U.S.A., Canada, the Netherlands, Scandinavia, and a number of other countries.

In some of these the bovine disease has been eradicated, or almost eradicated, by means of vaccination with an attenuated live vaccine (S19) followed eventually by slaughter. It has been estimated that in the U.S.A. losses from bovine brucellosis have been reduced from $100 million in 1947 to $40 million in 1957. The disease in man has also decreased, though not always at the same rate: in the United Kingdom the lag, so far as can be ascertained, seems to be particularly great.

With regard to the transmission of infection from animals to man two aspects are specially considered in this report—first, infection through fresh goat's-milk cheese, which is the chief infecting agent in some Central and South American countries and elsewhere, and secondly the importance of previously unsuspected animals, especially the hare, as agents of spread.

The committee lay down useful criteria for judging the efficacy of any therapy for undulant fever—criteria which are particularly important in a disease which before the introduction of antibiotics often terminated suddenly and spontaneously, and which under treatment by antibiotics often seems to behave similarly but yet relapses. The report sounds the salutary warning: "All forms of antibiotic therapy and chemotherapy currently in use are merely suppressive of the infection. ... The indiscriminate and uncritical administration of antibiotics for brucellosis offers certain hazards." Certain forms of chemotherapy (streptomycin or dihydrostreptomycin with sulphonamides, or the tetracyclines alone) are recommended. The use of corticosteroids for tiding over the toxic phase is mentioned, but extreme caution is urged in the use of these compounds.

In Russia an attenuated live vaccine (S19) has been used for the immunisation of human beings, but the committee regards such a procedure as still experimental. Of desensitisation with various antigens the committee remarks that "adequate desensitisation is difficult to accomplish and is usually transitory." But in many long-continuing cases chemotherapy is either ineffective or cannot be tolerated by the patient who has developed a high sensitivity to brucella toxins, and in such cases desensitisation is the only therapy available, and in the hands of some workers this has effectively banished the symptoms until the body's defences have restored a "comfortable symbiosis" On the animal side experiments on a large scale with the three vaccines already evolved for protection against caprine brucellosis are urgently recommended

[2] Joint F.A.O./W.H.O. Expert Committee on Brucellosis: third report. *Tech. Rep. Wld Hlth Org.* 1958, no. 148. Pp. 51. 3s. 6d. Obtainable from H.M. Stationery Office, P.O. box 569, London, S.E.1.

Finally in dealing with the interpretation and standardisation of diagnostic tests, the committee emphasises the importance of stating the results of seroagglutination tests in international units per millilitre, in order to facilitate comparison of data given by different methods

HELP FOR MOTHERS

FOR the past ten years a few pioneers have offered training and encouragement, instead of punishment and censure, to mothers who are not making a success of running their homes One of their early ventures, Spofforth Hall[1] near Harrogate, which was run by the Elizabeth Fry Memorial Trust of the Society of Friends, had to close about a year ago when its lease ran out, but the Trust is now opening its successor, which will be known as the Elizabeth Fry Home, at West Bank, Acomb, York The new premises have some advantages over the old Spofforth Hall was a lovely house, West Bank is in York and has smaller rooms and will seem less strange to the families who come for training The Trust will continue to take mothers accompanied by their younger children It hopes to accept those who may have been before the courts on a charge of child neglect as well as those sent by local health authorities who fear the breakup of a family As the home is within the city, the officers of the welfare and health departments will be able to take a greater part in the work than was possible at Spofforth Hall

University of Oxford

On July 12 the degree of B M was conferred on the following

Neville Rosen, M W Price, E H Stubbe, J R Harper, W P Metcalfe, David Negus, Alan Percival, J G Wood, D W C Dove, J C Anderson, James Freeman, P D Oldreive, R P Golding, W G Everett, J C Probert, M J Brown Janet A Bone, Julia D Dawkins, Isabel C A Greig, *M W Moncrieff, *John Dupré, *N H M McKinney, *M E Woolrych, *S D Weisbaum, *Mignon S Marston

* *In absentia*

University of St Andrews

The university court, acting with the Eastern Regional Hospital Board, has appointed Dr D M Green, senior lecturer in bacteriology at Queen's College, Dundee With the post is associated an honorary appointment from the regional board as assistant bacteriologist with the status of consultant Dr Green will take up his duties on Aug 1

Royal College of Obstetricians and Gynæcologists

On July 26 a meeting of the council was held with Prof A M Claye, the president, in the chair The following officers were re-elected

President, A M Claye, hon treasurer, A C H Bell, hon secretary, Ian Jackson, hon librarian, A J McNair, hon curator of the museum, Alan Brews, hon treasurer, Australian regional council, J N Chesterman, hon treasurer, Canadian regional council, G A Simpson, hon treasurer, New Zealand regional council, A M Rutherford, hon treasurer, South African regional council, F N Charnock

The following officers were elected

Vice-presidents, G F Gibberd, S W Maslen-Jones

The following were elected to the membership

Prabhavathy Aiman, Prasannatissa Harischandra Amarasinghe D T C Barber, C T H Barrett, W P Bonnici, John Breeze, J M Brudenell, D Pui-Chee Chan, H J H Claassens, C J T Craig, Dilip Ranjan Das, R M Davie, R F Drake, G R Duncan, G H Ellidge, W H Fernando L H Fienberg, J MacD G Harley, Denys Heginbotham, J B Hemsley, Alice Hsiang-Lien Hsu, P J Huntingford, Sylvia R Ingold, Katherine I Jack, R D Johnstone, E W P Jones, A J Keane, A C Keast, D M D King, Sybil V Kinley, Daphne R Lowe, John McGlone, Sheila Malhotra, Gouri Sankar Mandal, D T Mathews, Charu Chandra Mitra, Diana Montgomery, W P L Morrison, A D Muirhead, Salvino Muscat, Sapugahawattege Henry Piyadasa Nanayakkara, Isabella R Napier, Hannah J Pash, J H Peters, D W Pfanner, Carmen M Rant, D M Reader, W J C Rebello, John St George, Ajit Kumar Sarkar, P C Sutchbury, Jean O Struthers, W M E Tweed Radha Narayan Udipi, Thiagarajah Visvanathan, A W G Weir, Dorothy J Whitney, W G Wicks, Balasubramaniam Yoganathan

British Medical Association

Dr Walter Hedgcock has been appointed deputy secretary of the Association, and Dr D L Gullick and Dr J D J Havard assistant secretaries

Royal College of Physicians of Edinburgh

At a meeting of the college held on July 22, with Dr A Rae Gilchrist, the president, in the chair, the following were elected to the membership

T E Anderson, T N Macgregor, Wilfred Sircus, Pow Meng Yap, M F H Kelleher, Krishna Kumar Gupta, Amin Salim Jureidini, Rathni Vasant Kumar Alwa, Mohammed Abdul Ghani, Mahmoud Mohamed Hassan, J M Hughes, K J Cullen, E A Kauffmann, Jyotirup Chatterjee, Loku Banda Tennekoon Jayasundera, J G Wijeyesekera, Rajeshwar Prasad Sharma, Nirmala Haridas Gopaldas, J D E Knox, Arumakuttige Parakrama Jayasena Weerasekera, Raj Kishore Panda, Jacob Schneider, B W Petty, Akiwusi Abiola Akiwumi, Evelyn Hanam, D A Seaton, R D Catterall, J H A Dwek, Ram Nath Gupta, David Zentkowsky, Hau Cheong Kwaan, Maung Hla Myint, Thanuvelil Scaria Koshy, Anl Ali Hameedi, Dharamvir Narula, Rusi Jehangir Buhariwalla, Chun Thuan Lee, Werner Heinrich Schutt, Harry Stark, Batukrai Gulabrai Gandhi, Yong Kiat Lee, Kranti Prasad Jain

International Association of Gerontology

The first meeting of the European clinical section of this association is to be held at Sunderland General Hospital, from Oct 1 to 4 Further information can be had from Dr E Woodford-Williams, at the hospital, Chester Road, Sunderland

Institute of Laryngology and Otology, London

On Friday, Aug 8, at 5 30 P M at the institute, 330, Gray's Inn Road, W C 1, Dr Ben H Senturia, of St Louis, will speak on diseases of the external ear

Effects of Pollution on Living Matter

The Institute of Biology is holding a symposium on this subject on Sept 25 and 26, at the Royal Geographical Society, Kensington Gore, London, S W 7 Further particulars may be had from the secretary of the institute, 41, Queen's Gate, S W 7

Conference on General Practice

The *Medical World* is holding a conference on general practice in the Victoria Halls, Bloomsbury Square, London, W C 1, on Sunday, Oct 26 Tickets (*10s 6d*) may be had from the conference organiser, 56, Russell Square, W C 1

The Medical Insurance Agency

The 30th annual meeting was held at B M A House, London, on July 24 The report of the committee of management disclosed new records of business done in all branches new high levels of assurances have been negotiated and higher profits have been allocated to medical charities The report ended with a claim that the agency's work is of great service to the profession, that more and more doctors recognise that this is so, and that in reputation and esteem it has never before stood so high

Sir Russell Brain and Sir Cecil Wakeley were elected to the committee Retiring members re-elected were Dr James Fenton, Sir Archibald Gray, Mr A M A Moore, Mr Ronald Raven, Dr Oliver Scott, Mr Ben Thomas, and Sir Henry Tidy Dr Fenton was re-elected chairman, and Dr Henry Robinson hon secretary The report contained an emphatic tribute to the work of the general manager, Mr A N Dixon, and his staff

St Clement's Hospital, Bow

King Edward's Hospital Fund for London are to make a grant of £50,000 to help the North East Metropolitan Regional Board in their plans for developing this hospital as a modern psychiatric hospital

The hospital already has an observation ward and a small unit for cases of psychoneurosis, and as the board think that in the future the hospital will no longer be needed for the general hospital needs of the area, they have decided to extend the psychiatric work with the ultimate object of establishing a modern neuropsychiatric centre for East London, which will provide full facilities for the investigation and treatment of all types of acute mental illness, as well as for teaching and research As a first step it is proposed to refurbish a three-storey block at the hospital which is at present derelict, and to set up a day hospital for old people in the early stages of mental deterioration This unit would be combined with a domiciliary service in cooperation with the local authority Apart from the day hospital, it is intended to provide an inpatient unit for severely disturbed young patients and to extend the occupational therapy and outpatient departments The first stage of the plan will cost about £59,000, and the gift from the King's Fund will enable the board to approach the Minister of Health for approval to embark on this project

CEREBRAL VASCULAR DISEASE IN THE LIGHT OF MODERN TECHNIQUES *

J St C Elkington
M.D Cantab., F.R.C P

PHYSICIAN-IN-CHARGE, NEUROLOGICAL DEPARTMENT, ST THOMAS'S HOSPITAL, LONDON, S.E.1, PHYSICIAN, THE NATIONAL HOSPITAL, QUEEN SQUARE, LONDON, W C.1

Cerebral vascular disease is of great and, one fears, of still growing importance in Western society It would be a fascinating historical study to examine the part it has played in the history of the last two thousand years with its stories of the gradual decline or perversion of powerful regimes and of the violent oscillations of events brought about by the sudden removal of some outstanding personality from the scene of human affairs

Some idea of its importance in contemporary society can be obtained from a brief reference to the Registrar-General's Statistical Review for England and Wales in which the annual deaths from cerebral vascular disease over the ten-year period 1946-55 are compared with those from arteriosclerotic heart-disease and from carcinoma of the bronchus and lung—two disorders much in the public eye at the present time. Fig 1 shows that the toll of cerebral vascular disease in every case surpassed that of the other two, and during the first half of the period exceeded their sum often by a considerable margin American figures tell the same story Wright and Luckey (1955) record that in 1952 there were 172,000 deaths from cerebral vascular disease—a figure exceeding by three times the combined deaths from diabetes and tuberculosis These figures give no idea of the amount of chronic illness and of premature incapacity which, because of its nature, cerebral vascular disease inflicts upon society

Old enemies, like old friends, are apt to be taken for granted and cerebral vascular disease is no exception This is aptly illustrated by an extract from a clinical lecture published fifty years ago (Rose Bradford 1908) Speaking of cerebral aneurysms the lecturer said that these might give rise to no symptoms till they ruptured, adding "These cases are of no clinical interest, they are merely cases of cerebral hæmorrhage" This statement cannot have seemed as unusual in those days as it does today, for twenty years later the speaker was president of this college.

It might be said that the last twenty years have not added greatly to our fundamental knowledge of cerebral vascular disease, but the developments in cerebral and vascular surgery and of surgical techniques, especially radiology, have thrown notable light on its details and have opened up new possibilities both in diagnosis and treatment It is against this changing background that I propose to review the subject, selecting for particular discussion those aspects in which modern techniques have brought greater accuracy in diagnosis and are gradually bringing about a modification of orthodox attitudes towards management and treatment

Classification

To have any hope of success an attempt to review so large a field requires a schema by which the subject may be broken down into manageable subsections, and, while being fully aware of its scientific imperfections, I propose to employ the following classification It will be understood that in any individual patient more than one variant of cerebral vascular disease may exist at the same time

Diffuse
(*a*) Generalised ischæmic brain degeneration from atherosclerosis.
(*b*) Cerebral disorder in arterial hypertension.

Local
(*a*) Focal softenings from ischæmia, including occlusion of minor vessels by thrombosis or embolism.
(*b*) Massive softenings from ischæmia, including occlusion of major vessels by thrombosis or embolism
  (1) Internal carotid artery occlusion
  (2) Basilar artery occlusion.
(*c*) Intracranial hæmorrhage
  (1) Meningeal hæmorrhage
    (i) Extradural
    (ii) Subdural.
    (iii) Subarachnoid.
  (2) Intracerebral hæmorrhage.

Generalised Ischæmic Brain Disease from Atherosclerosis

Though diffuse ischæmic brain disease is quantitatively the most important manifestation of cerebral vascular disease it need occupy only a few moments of our time, for its features are well known and have hardly been affected by modern advances It is essentially the end-result of atherosclerosis with or without hypertension and such occasional aggravating factors as alcohol or head injury.

In many cases it is a disorder of gradual progression but its course may be punctuated by outspoken vascular accidents of greater or less severity

Its most striking feature is progressive mental deterioration. At first the gradual falling off of the individual's innate creative capacity and of his desire and ability to meet new situations, together with a closing in of the mental horizon and an increasing egoism, may seem to be no more than the natural effects of advancing years Forgetfulness, first for recent and then for more remote events, loss of capacity for all but familiar intellectual activities, accentuation of the underlying qualities of the personality, mood changes, decrease in emotional stability, and periods of confusion mark its advance into the realm of the pathological Finally, a state of profound dementia supervenes, differing only in detail from that seen in other conditions of generalised brain destruction This is a picture well known to us all We see it in the world around us It may fall to the lot of any of us to detect its earliest manifestations in ourselves, though it must be admitted that loss of insight is amongst the earliest features of this insidious disorder

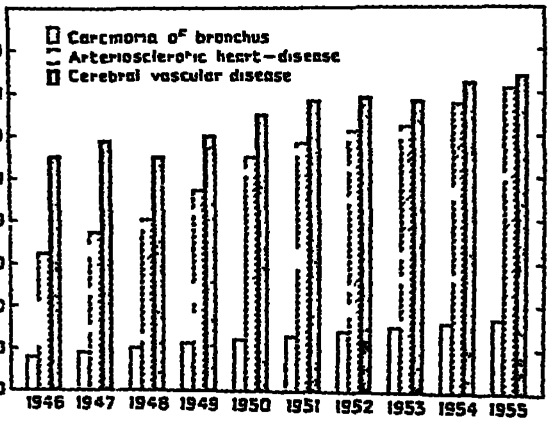

Fig 1—Deaths from carcinoma of bronchus, arteriosclerotic heart-disease, and cerebral vascular disease in England and Wales, 1946-55.

---

* The first Lumleian lecture for 1958, delivered before the Royal College of Physicians of London on April 15

Less familiar to many are the physical symptoms which may accompany and sometimes precede the mental change of diffuse ischæmic brain disease Loss of physical agility may pass imperceptibly into lack of balance The natural resilience of the gait is replaced by shuffling steps The voice takes on a monotonous quality which is the prelude to a spastic dysarthria Dyspraxia of the limbs and trunk adds its frustration to the effects of mental confusion and evokes outbursts of weeping or of laughter Years of bedridden dependence upon others for the most elementary necessities of life may precede the patient's final release

Such is a picture that has not changed through the centuries and which seems unlikely to change until we have some effective method of arresting arterial degeneration in general and atheroma in particular

Cerebral Disorder in Arterial Hypertension

This interesting manifestation of cerebral vascular disease, often referred to as hypertensive encephalopathy, may be superimposed upon the background of ischæmic brain disease or may exist independently It may occur in association with severe degrees of hypertension from whatever cause—e g , in essential hypertension, unilateral renal disease, toxæmia of pregnancy, or rare disorders such as porphyria

Its symptoms are both mental and physical, but these share in common a remarkable tendency to fluctuate in severity such as is seldom observed in other forms of vascular brain disease

In the mental sphere, anxiety, confusion merging into delirium, and alterations of consciousness are more conspicuous than dementia On the physical side, epileptic fits either generalised or focal are common Manifestations of local brain dysfunction, such as blindness, loss of speech, and hemiplegia or monoplegia, having all the features of similar events due to vascular accidents, may suddenly make their appearance only to disappear in the course of a few days Hypertensive retinopathy is commonly present, and varying degrees of hypertensive heart-failure may complicate the picture

In spite of much that has been written, the underlying pathology of hypertensive encephalopathy remains obscure If not directly dependent upon the degree of arterial hypertension, it is clearly closely related to this and as with retinopathy it is seldom seen with a diastolic pressure of less than 130 mm Hg The features of the mental picture suggest that we are here dealing with a diffuse process, while the focal symptoms indicate local involvement of portions of the brain The rapid fluctuations in the severity of the symptoms both mental and physical can only be satisfactorily explained by a process which, at any rate initially, is reversible

Œdema of the brain substance and nerve-cell anoxia from arteriolar spasm or from general slowing of the cerebral circulation suggest themselves as possible explanations In hypertensive subjects the cerebral blood-flow is known to be significantly reduced Denny-Brown (1951) believes that the changes are associated with multiple small cerebral lesions associated with small arterial occlusions Pickering (1948) suggests that in cases of acute hypertension œdema of the brain is responsible, whereas in the hypertensive crises occurring in more chronic cases occlusion of small arteries is the cause Foley (1956) finds the histological accompaniments of hypertensive encephalopathy to consist largely of swelling, miliary infarcts, petechial hæmorrhages, and evidence of increased vascular permeability, superimposed upon more chronic vascular lesions

Whatever may ultimately prove to be the correct explanation of the phenomena of hypertensive encephalopathy, its general relationship to the level of th blood-pressure, and in particular to that of the diastol blood-pressure, clearly demands that it should be give consideration in relation to the treatment of hypertensio as a whole

Much has been written in the past twenty years on th treatment of arterial hypertension The era of thoracolumbar sympathectomy was followed by that of ganglion-blocking agents and of other drugs ' Numerous series o cases have been published showing the effect of these procedures on the blood-pressure and on the patient's symptoms No final conclusions can yet be drawn, and no doubt other hypotensive agents await discovery In the series of cases published up to now relatively little reference is made to the effects of hypotensive therapy on the symptoms of hypertensive encephalopathy These, admittedly, are more difficult to measure than the blood-pressure or the manifestations of cardiac embarrassment But on the whole what comment there is seems to be unfavourable Smirk and Alstad (1951) in their comparatively small series state that the incidence of encephalopathic attacks was not obviously altered Shirley Smith (1954) and his colleagues go so far as to include "more than slight cerebral disorder" among the contraindications to the use of hexamethonium compounds Graham and Maxwell (1954), on the other hand, include encephalopathy among their indications for urgent treatment

My own impression has been more favourable to the value of hypotensive therapy in encephalopathy In cases presenting primarily on account of cerebral symptoms it has seemed to me that effective lowering of the blood-pressure, however this is achieved, results in gratifying improvement both in the mental and the physical manifestations of encephalopathy, and I associate myself with those who take the view that even severe encephalopathy is a positive indication for hypotensive treatment, without committing myself to any final opinion as to which method of reducing the blood-pressure is to be preferred

Focal Softenings from Ischæmia

The occurrence of "threatened" or "minor" strokes, often of a repetitive character, is a common event and in the past they have been attributed to the results of occlusion by thrombosis or embolism of the terminal branches of the cerebral vascular tree, to arterial spasm, or, in the presence of hypertension, to small hæmorrhages In many cases this attribution is, no doubt, correct The underlying pathology is diverse, and in conditions such as syphilis or infective endocarditis it may be amenable to direct curative treatment But in the vast majority of such cases the underlying cause is atherosclerosis, and the patient's recovery depends upon the natural powers of readjustment, which are considerable In the past, the degree to which the brain was supplied by end-arteries was overstressed, and Rosegay et al (Rosegay and Welch 1954), among others, have demonstrated very clearly by angiographic studies the extent to which the collateral pial circulation from the anterior and posterior cerebral arteries may supply the area of cortex normally supplied by the middle cerebral artery when this vessel has become occluded

It has long been known to pathologists that in brains examined after such incidents the extent of demonstrable infarction was often much smaller than might have been expected from the clinical symptoms, and that in a considerable proportion of cases of infarction the most careful search has failed to reveal occlusion of the lumen of the artery supplying the damaged area

These observations and the facts which have emerged as a result of the better recognition of the syndromes of occlusion of the carotid and basilar arteries, which will be considered later, have led Denny-Brown and his co-workers (Denny-Brown 1951, Meyer et al 1956, Meyer and Denny-Brown 1957a and b) and later Corday et al (1953, 1956) to postulate the state of "cerebral vascular insufficiency" as an alternative to "vasospasm", which has often been held to explain these occurrences Denny-Brown defines "cerebral vascular insufficiency" in physiological terms as "a state of local or general cerebral blood flow that is unable to maintain the metabolic requirements of the brain during physiological stress" This state may be overt, leading to symptoms and signs during the stresses of normal life, or it may be latent and become manifest only as a result of some special stress—particularly an abrupt fall in the systemic blood-pressure

The condition is the result of narrowing or occlusion, through organic changes, of the arteries—often at a point remote from their terminal distribution This leads to the brain tissue becoming dependent for its blood-supply upon collateral branches from neighbouring vessels, this supply is adequate for ordinary purposes but falls below the critical requirement in the event of a sudden fall in the systemic blood-pressure or a further narrowing of the collateral vessel itself

Denny-Brown and his associates have reproduced the clinical events observed *in man* in a series of beautiful experiments on monkeys after ligation of the common carotid or middle cerebral arteries

Ligation of the middle cerebral artery under normal circumstances produces no demonstrable effects, the collateral circulation through the anterior and posterior cerebral arteries being fully adequate to maintain normal function If, however, in such an animal the systemic blood-pressure was reduced by any means or the oxygen content of the blood diminished by breathing nitrogen a series of events was observed which closely paralleled those of a minor stroke First, changes appeared in the electroencephalographic (E E G) record of the effected area with failure of the normal electrocorticogram and the appearance of an injury potential, both changes, initially, being readily reversible If, however, the hypoxic state was maintained stasis appeared in the smallest venules together with evidence of increased permeability of capillaries Again these changes were initially reversible, but, if the anoxia were maintained, contiguous foci coalesced with the production of an irreversible infarct

Denny-Brown and his colleagues conclude therefore that such infarcts are the result of tissue anoxia and that thrombosis of cortical vessels plays no part in their initial development

USE OF ANTICOAGULANTS

The introduction during the past ten years or so of anticoagulant drugs suitable for prolonged administration has raised the question of whether these drugs have a useful part to play in the subsequent care of patients who have recovered from the effects of a minor stroke Their value seems to be established in the immediate treatment of coronary artery occlusion, and many cardiologists advocate their continued and indefinite use in patients who have recovered from such an incident (e g, Foley and Wright 1950, 1956, Wright 1955, Wright and McDevitt 1954)

However, the conditions in the heart and in the brain are not wholly comparable The liability to an extension or an early recurrence of the occlusion is greater in the heart, whereas the risk of hæmorrhage into a softened area is peculiar to the brain. While recognising its risks and limitations, prolonged anticoagulant treatment is warmly advocated by Wright and his collaborators and by Millikan et al (1955) In the nicely balanced conditions occurring in the brain the point can only be decided on a practical basis

There would seem here to be an admirable opportunity for a properly controlled long-term investigation, which could only be adequately carried out in an institution caring for a large number of chronic sick and senile patients Alternate cases considered to be at risk should be maintained on anticoagulants for the remainder of their lives and the occurrence of thromboembolic incidents estimated annually in both treated and untreated cases throughout their *period of survival*

Occlusion of the Internal Carotid and Basilar Arteries

The brain receives its blood-supply from four arteries—the two internal carotids and the two vertebrals—the latter joining together to form the basilar

The carotids and the basilar are of comparable size and are subject to the same disorders, of which atherosclerosis, aneurysm formation, and embolic occlusion are the chief The three arteries enter into the formation of the circle of Willis, formed by the linking up of their terminal branches by the anterior and the two posterior communicating arteries

In the normal and healthy subject this delicately arranged anastomosis serves to provide an alternative basic blood-supply to all parts of the brain so that either carotid and probably the basilar, provided it is only occluded over a short distance, can be eliminated without disastrous results It has been shown by McDonald and Potter (1951) in the rabbit that the blood-flow through the posterior communicating arteries is normally zero, and that the same is probably true of the anterior communicating The results of angiography suggest that the same is true in man so that in the normal, healthy subject the vascular fields supplied by the two carotids and the basilar remain distinct except at their periphery where they mingle at an arteriolar level

But not all people are normal, nor are they all healthy. Congenital anomalies in the formation of the circle of Willis are common Dandy (1944) stated that a "strictly normal" circle of Willis occurs only in 50% of cases Defects in the posterior communicating arteries are especially frequent Stopford (1916) found this vessel to be absent on one side in 6% and on both sides in 4% of specimens examined Furthermore, the vessels entering into the formation of the circle are peculiarly prone to the premature changes of atheroma Either type of defect, the congenital or the acquired, decreases the efficiency of the natural provision for an alternative blood-supply and increases the risk of disaster should any further occlusion take place Catastrophe may be brought about by some event affecting the efficiency of the circulation as a whole, such as the lowering of the blood-pressure by a blood donation or by an attack of gastrointestinal hæmorrhage (Denny-Brown 1951)

Occlusion of the carotid or basilar arteries may be brought about by a variety of pathological processes, but the results are largely independent of the cause and are determined rather by the anatomical facts peculiar to the individual and by the general state of the cerebral circulation at the time Embolism from any cause may be responsible The carotid because of its length and its position may suffer from the results of trauma Occasionally occlusion occurs in apparently healthy young people in whom the cause may remain undetermined Such incidents are more commonly met with in the carotid than in the basilar artery

Case 1—A healthy young policeman, aged 24, attended hospital on account of weakness and clumsiness of the right hand for two weeks This had become apparent one day on parade when he found himself unable to carry out items of his drill requiring the use of the right hand In retrospect he recalled that for several months he had been liable to drop things out of it On examination at that time the only abnormal sign was loss of fine movement in the right hand with partial loss of postural sense and tactile discrimination in the fingers General examination was negative He made a complete recovery in a few weeks, and the diagnosis of disseminated sclerosis was thought most likely

Some six months later while in Malaya he played a vigorous game of rugby football During the following evening he felt generally unwell After sleeping he woke suddenly in the morning feeling very ill and discovered that he was completely paralysed on the right side and was unable to speak

After several weeks of mental confusion he was flown home where he was found to have a severe right hemiplegia, right hemisensory loss, and a right homonomous hemianopia He had severe mixed dysphasia General examination was still negative A left carotid angiogram showed complete occlusion of the left internal carotid artery 1 cm distal to the bifurcation of the common carotid artery

No cause for this was found Ten years later his general condition remains normal The ætiology of the thrombosis remains unknown

By far the commonest cause of occlusion both of the carotid and of the basilar arteries is atherosclerosis, and the patients are usually in the fifth or later decades of life

Atheroma, though affecting major- and medium-sized arteries generally, has a special preference for certain sites among which the carotid, vertebral, and cerebral arteries are conspicuous As has been so clearly shown by Hutchinson and Yates (1957), in any given case the carotid and vertebral systems are comparably affected and in considering the consequences of occlusion in either territory it is essential to bear in mind what may be taking place in the other In short we have to accustom ourselves to thinking always in terms of caroticobasilar insufficiency The same lesson is brought home by the results of both carotid and basilar angiography in atheromatous subjects

Atherosclerosis affects the carotid and basilar arteries in several ways Firstly, the arteries become tortuous and may eventually be subjected to such sharp kinking that relative stenosis of the lumen is brought about Secondly, the weakening of the media may lead to aneurysm formation Saccular aneurysms of the carotid artery in the cavernous sinus are relatively common, and fusiform aneurysms of the basilar artery are not very rare Such aneurysms may undergo gradual thrombosis which may spread to the lumen of the artery or give rise to embolism in its branches

Finally the intima of the vessel may become ulcerated with the development of a localised mural thrombosis, which in its turn may lead to a massive thrombosis and occasionally to embolism This process of occlusion is often gradual, and cross sections of the artery may show lamination of the clot with recanalisation in its older parts

Although in the respects that have been mentioned the carotid and basilar arteries are similarly affected and must always be considered in relation to one another, the syndromes that result from their final occlusion are sufficiently distinct for them to be considered separately

INSUFFICIENCY AND OCCLUSION OF THE INTERNAL CAROTID ARTERY

The occurrence of massive occlusion of the internal carotid artery has been recognised for many years, but interest in it has been greatly stimulated in the past decade, largely as a result of the development of cerebral angiography It is now recognised to be much common than would have been admitted ten years ago In additi to isolated case-records, small collected series have bee reported by Moniz and de Lacerda (1937), Gurdjian a Webster (1949, 1951), Elvidge and Werner (1951), Johns and Walker (1951), Smyth (1954), Thomson (195 Silversides (1954), and Shapiro and Peyton (1954)

The following brief account is based upon a study the records of 32 cases who have been under the ca either of myself or of my colleagues during the past fi years, as well as of the reported cases Published seri *show general agreement that the condition is common* in males than in females in the proportion of about thre to one, and that the left side is affected more commonl than the right in about the same ratio My own figures a in agreement The majority of the cases occur in the fift sixth, and seventh decades of life, but a significant numbe occur in young adults in their twenties and thirties, henc the average age of carotid occlusion is significantly lowe than that of basilar occlusion *This extension into younge* age-groups is partly accounted for by trauma, but in considerable number the causation has remained in doubt Antoni (1941) and Krayenbuhl and Weber (1944) hav attributed such cases to thromboangiitis obliterans, bu none of their patients has shown evidence of this diseas elsewhere in the body or any of the ætiological feature characteristic of it The majority of workers view the accuracy of this attribution with doubt

There is general agreement that the principal ætiological factor is atherosclerosis, which may manifest itself in the early decades of life, particularly in the neighbourhood of the bifurcation of the common carotid artery

The clinical picture of carotid thrombosis varies within wide limits

At one extreme are the cases which present *themselves in* the form of massive contralateral hemiplegia coming on rapidly without warning and usually associated with depression or loss of consciousness Gowers (1888) remarked on the relative rareness of such cases If consciousness is sufficiently preserved, contralateral sensory disturbance and not infrequently homonomous hemianopia may be demonstrable With a right hemiplegia severe dysphasia is the rule Severe supraorbital headache may occur on the side of the diseased artery Not uncommonly a unilateral or generalised convulsion heralds the onset Blindness in the ipsilateral eye with narrowing of the retinal arteries and subsequent optic atrophy, although pathognomonic of carotid occlusion when it occurs, is relatively rare since the circulation through the ophthalmic artery is usually maintained either from the opposite internal carotid through the anterior communicating artery or by anastomosis with orbital branches of the external carotid Occasionally papillœdema is present

In patients who survive the immediate effects of the stroke, recovery sets in after a week or ten days and continues for *many months* The hemiplegia shows considerable improvement especially in the leg, the arm remaining severely affected and the hand useless

Where the major hemisphere has been damaged, the dysphasia improves but usually persists in some degree indefinitely, especially as regards spoken speech, and with it is found some mental deterioration and euphoria Hemianopia may or may not persist, *and if it does is likely to* involve the lower more severely than the upper quadrants

The picture thus comes to resemble that of occlusion of the middle cerebral artery, for which it is often mistaken Subsequent angiograms of the unaffected carotid artery may demonstrate the filling of the anterior cerebral artery on the affected side through the anterior communicating artery

Case 2 —A previously healthy man of 33, six weeks before admission, was given a tablet of 'Seconesin' on account of anxiety symptoms, to which he was subject This was followed in fifteen minutes by wide-spread urticaria He was given an injection of adrenaline which enabled him to go to sleep Four hours later he had a fit in his sleep and on being woken next morning he was found to be drowsy, totally aphasic and paralysed on the right side of his body When examined he was euphoric and still showed severe dysphasia Vision and the visual fields were full He had a right hemiplegia, complete in the upper limb and severe in the face and lower limb, together with slight general diminution of sensation on the right side of the body General medical examination was negative Blood-pressure 130/80 mm Hg

A left carotid angiogram showed complete occlusion of the internal carotid artery $^1/_2$ in above the bifurcation of the common carotid This was confirmed by operation

Subsequently the patient's condition has improved somewhat

At the other extreme carotid occlusion may cause no neurological symptoms at all Such an occurrence, in a man dying of cancer, was recorded with expressions of surprise by Willis himself, who also noted that the patient had been troubled by severe headache on the opposite side of his head It has long been known that in the majority of people surgical ligation of the internal carotid artery can be carried out with, at most, transient contralateral hemiparesis

Under such circumstances the collateral circulation through the anterior and posterior communicating arteries must be sufficient to maintain normal function. As has already been said, congenital defects or degenerative changes in the circle of Willis may interfere with the efficiency of this compensating mechanism The likelihood of hemiplegia occurring after carotid ligation thus increases with increasing age and is correspondingly lessened when the process of occlusion is gradual

It is not possible to state with certainty what is the incidence of such symptomless thrombosis, but Hultquist (1942) found occlusion of one carotid in 4 4% of 1300 routine necropsies, and Fisher (1954) found complete occlusion in one or both internal carotids in 28 (6 5%) of 432 unselected necropsies

Between these two extremes carotid occlusion more commonly shows itself in one of two recognisable clinical forms which may also occur in the presence of stenosis of the artery and before the lumen has become completely occluded

The first, and by far the commonest, is that of transient episodes of unilateral disturbance recurring at irregular intervals over many months or years For this syndrome Ramsay Hunt (1914) coined the appropriate phrase "cerebral intermittent claudication" Of these episodes the commonest is transitory numbness or weakness of one hand Sometimes this will involve simultaneously the same side of the face or the whole half-body, and at other times the hemiplegia though transient may be complete

The right side of the body is much the more commonly affected since the underlying change more often affects the left carotid, and right-sided attacks are usually associated with temporary loss of speech. Such aphasic attacks may be the sole symptom

Other patients may report transitory loss or partial loss of vision in one eye, which may be mistaken for migraine—a mistake made easier by the common occurrence at the same time of unilateral headache

Others may notice attacks of "dizziness", by which they mean a feeling of confusion and impairment of consciousness rather than of vertigo Rarely, fits—focal or general—may occur.

Case 3 —A previously healthy man of 67 gave a history of four transitory attacks of weakness and numbness on the left side of the body in four weeks The first episode came on without warning and consisted of sudden loss of power in the left hand and arm lasting only a few minutes In subsequent attacks there was also numbness throughout the left half of the body During the same period he noticed a tendency to bump into objects on his left and also rather severe intermittent headaches On examination the only abnormal sign was a partial left homonomous quadrantic field defect A right carotid angiogram showed complete occlusion of the right internal carotid artery

The exact explanation of these transitory episodes was for some time disputed They clearly could not be explained by thrombosis of the carotid artery as such since they might last only for seconds or minutes The theory of "vasospasm" in the distal branches of the diseased artery has been much canvassed, especially by French and other Continental writers, on the analogy of the arterial spasm which has been observed to occur on puncture or other injury to the arterial wall But direct evidence of such vasospasm was lacking, and such measures as stellate block or stripping of the nerve plexus in the adventitia of the artery have not, in the experience of most workers, proved successful in preventing such attacks Some cases may be due to embolism into the distal branches of the affected carotid, but usually the attacks are too frequent, too stereotyped, and too transient to be explained on this basis

The more satisfactory explanation is that of Denny-Brown who, as we have seen, believes them to be due to transitory ischaemia from failure of a collateral circulation which has hitherto maintained an adequate blood-flow in the distal branches of the occluded artery He believes that the collateral circulation fails as a result of some decrease in the general cerebral circulation such as may follow a fall in the systemic blood-pressure or a decrease of the cardiac output from any of a wide variety of causes

This explanation is the more satisfying since we now know that these attacks may occur in cases of carotid stenosis, before actual occlusion of the lumen has taken place, and since they have now been so exactly reproduced experimentally

Finally, occlusion of the carotid artery may give rise to a gradually developing contralateral hemiplegia, initially most severe in the hand and face and often associated with dysphasia In time the whole half-body is affected but the leg remains less damaged than the arm In such cases focal or unilateral fits may occur, and headache on the side of the diseased artery may be severe Such patients are usually thought to have a cerebral tumour, and it is during their routine investigation by angiography that a considerable number of the recorded cases of carotid occlusion have been discovered

Case 4 —A woman of 50 was admitted for investigation because she was thought to have a cerebral tumour Previously healthy, she was noticed some five months before admission to be becoming forgetful and apathetic After some weeks she was reported to have had two seizures in one of which she became generally rigid and in the other she lost consciousness and shaking developed in the right arm and leg Gradually a right hemiplegia developed, and a few days before admission her speech became disturbed and finally lost

On examination she was drowsy and severely dysphasic She had a right homonomous hemianopia without papilloedema, and a right hemiplegia, complete in the upper limb and severe in the lower limb General examination was negative Blood-pressure 110/70 mm Hg

Ventriculography was first performed with negative findings Bilateral carotid angiograms revealed thrombosis of the left internal carotid artery immediately distal to the origin of the posterior communicating artery She survived and showed slight improvement in the severity of her hemiplegia

Clinical Confirmation

In suspected cases of carotid occlusion the diagnosis can sometimes be confirmed by palpating the vessels in the neck (Ramsay Hunt 1914) If the common carotid artery is also involved absence of pulsation at the level of the bifurcation as well as in the superficial temporal and facial branches of the external carotid artery may be readily demonstrable If the internal carotid artery only is involved the difference on the two sides may be detectable, but confusion with the external carotid artery and its major branches makes the test difficult to apply and unreliable in its results

Palpation of the internal carotid artery from the pharynx (Gurdjian and Webster 1949) is a test most observers have found unsatisfactory Decrease in the arterial blood-pressure in the optic fundus may be demonstrated by digital or instrumental pressure on the eye during ophthalmoscopic examination Compression of the opposite carotid artery may be followed by immediate impairment of consciousness and if persisted in by convulsions, but this test should be used with restraint

Absolute Confirmation

Absolute confirmation of the diagnosis can be made by carotid angiography or by surgical exploration It is the development of the former technique that has revealed the relative commonness of carotid occlusion and of carotid stenosis and has stimulated contemporary interest in the subject

The obstruction is usually at the level of the bifurcation of the common carotid or within 3 cm above it (fig 2) In 22 patients Thomson (1954) found this to be the case in 16 cases, 5 occurring in the carotid syphon and 1 in the common carotid artery

In addition to the cases in which complete occlusion of the lumen is demonstrable, stenosis of the artery through the presence of an atheromatous area of the wall and a mural thrombus can sometimes be detected (fig 3)

INSUFFICIENCY AND OCCLUSION OF THE BASILAR ARTERY

The results of occlusion of the basilar artery have much in common with those of occlusion of the carotid artery Here, too, the important ætiological factors are embolism and atherosclerosis, the latter being much the more common The average age at onset is higher than in the case of carotid occlusion Cases of thrombosis below the age of 50 are rare Interest in the subject was greatly stimulated by the paper of Kubik and Adams (1946) based on a clinico-pathological study of 18 cases examined at necropsy But the clinical picture associated with basilar occlusion had long been recognised, as the following quotation will show

> "In occlusion of the whole basilar the limbs of both sides are usually affected Sometimes at the same time, sometimes successively in the course of a few days The limbs on one side, for instance, may become weak and improve, a day or two afterwards the other side becomes weak, and then there is again loss in the side first affected The affection of the facial

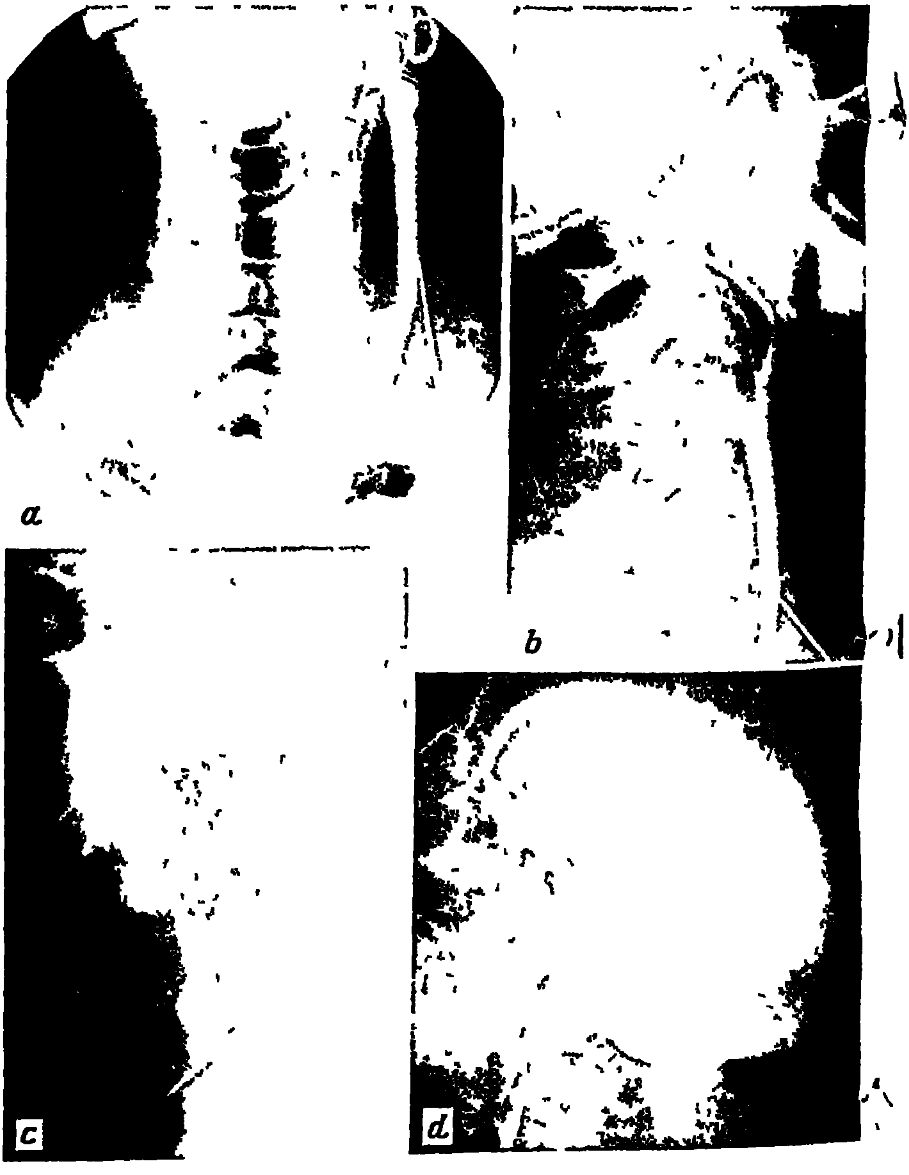

Fig 2—Illustrative examples of occlusion of the internal carotid artery immediately distal to the carotid bifurcation (*a*) in anteroposterior view, (*b*), (*c*) and (*d*) in lateral view

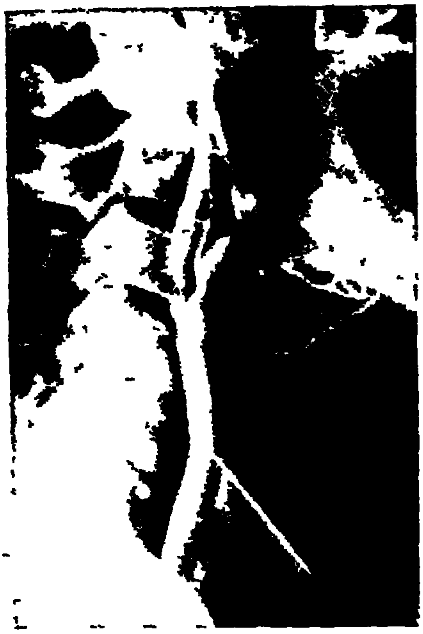

Fig 3—Stenosis of the internal carotid artery from atheroma immediately distal to the carotid bifurcation

or fifth nerve may present the same variations and often does not correspond to the affection of the limbs There is usually considerable impairment of articulation and of swallowing Loss of the conjugate movement of the eyes from palsy of external and internal recti is occasionally observed, with or without palsy of the facial nerve on the side of the affected external rectus When the obstruction involves the upper part of the vessel, as is usually the case in embolism, there are usually ocular symptoms other than conjugate deviation, ptosis, contracted or dilated pupils, with loss of reflex action to light, sometimes transient There is occasionally paralysis of the whole or part of one third nerve or even of both Less common is hemianopia, from extension of the clot along one posterior cerebral beyond the origin of the posterior communicating artery Bilateral loss of sight, theoretically possible, is excessively rare Obstruction of the lower extremity of the basilar is not common, except as an extension of a clot from one of the vertebral arteries The onset of obstruction of the basilar artery is usually attended with a distinct apoplectic seizure, usually transient, it often recurs, and gradually deepens The patient may lie for some days in a state of incomplete coma, can be roused to open his eyes, but does not speak Convulsions occasionally attend the onset, but are on the whole not frequent, they may be general or partial, one limb or one side of the face may escape Rigidity or clonic spasm in the legs or arms is much less common than in hæmorrhage into the pons "

This quotation is taken from Gowers' *Textbook of Nervous Diseases* (American edition) dated 1888, and could hardly be improved upon as a description of the clinical picture of massive basilar occlusion Little needs to be added to it in the light of more recent knowledge, but a few comments may be made The frequent depression or loss of consciousness, even in cases where the occipital lobes are not involved, is of especial interest with regard to the part played by brain-stem structures in the function of consciousness, which was till recently looked upon as dependent upon cortical activity A symptom not mentioned by Gowers and now recognised as occurring in the majority of cases is severe headache, usually fronto-occipital This is probably due to congestion of healthy vessels as a result of overloading of the collateral circulation

Massive occlusion of the basilar artery is commonly fatal, but the period of survival varies over a wide range In many of the reported cases the patient has died within two to three days of the onset of severe symptoms, while others have survived for from six to eight weeks In less severe cases recovery may occur with varying degrees of residual disability, and, as will be seen later, such cases are probably more common than was previously recognised

Case 5 —A man, aged 56, was admitted to hospital on March 1, 1956 Having previously been healthy he sustained, in 1942, a machine-gun wound of the spine which destroyed the spinal cord in its lumbosacral enlargement, rendering him totally and permanently paraplegic.

He made a good adjustment to his disability and led an active life as a school bursar, but developed a chronic urinary infection and was known to be hypertensive with blood-pressure around 230/130 mm Hg In November, 1955, he began to experience recurrent attacks in which for a few minutes he would feel faint and his sight would become blurred Occasionally this blurring was associated with double vision Three days before admission, having had such an episode in the morning, he was found by his wife some hours later unconscious in the lavatory He was cyanosed and twitching on the left side of his body He was admitted to hospital where it was observed that both arms were ataxic and that his speech was disturbed Within a few hours he was unable to speak or to swallow.

When examined in the National Hospital on March 1, he was conscious but unable to speak He could understand and obey simple commands and appeared to have normal fields of vision Apart from the presence of nystagmus, his ocular movements were normal and the fifth-nerve functions were unimpaired There was left facial weakness and the tongue deviated to the left on protrusion As far as examination was possible he seemed to have a spastic weakness of the left arm and some ataxia of both but especially the left Sensation above the waist was normal The lower part of the body had the signs of complete transection of the cord in the upper lumbar region

On the suspicion that the patient was suffering from thrombosis of the right internal carotid artery, a right carotid angiogram was done through the common carotid This was normal except for some irregularity of the vessels suggesting atherosclerosis

In the next two days the picture changed Complete anarthria and aphagia were present The respirations became periodic and the cough ineffective Conjugate deviation of the eyes was lost Both corneal reflexes disappeared and flaccid paralysis developed in the masticatory and facial muscles on both sides Both arms were in a condition indicative of a double hemiplegia

Basilar thrombosis was diagnosed and a vertebral angiogram performed (fig 4) and reported on as follows "A very small quantity of contrast medium is seen at the most superior part of the basilar artery in the lateral view, it is very thin and measures less than 1 mm in diameter In the anteroposterior view the left vertebral artery can be seen to be occluded 4 5 cm from where it forms the basilar This part of the artery has a beaded appearance In the anteroposterior view also the proximal part of the basilar can be seen, and is also narrow and irregular The appearances are very suggestive of a thrombosis of the left vertebral and basilar arteries "

As far as I am aware, this was the first occasion on which occlusion of the basilar artery was demonstrated angiographically during life The patient died six weeks later

At necropsy, in addition to cardiomegaly and the results of a longstanding paraplegia, there was widespread and advanced atherosclerosis The basilar artery was dilated and tortuous and its lumen completely occluded by thrombus below the level of origin of the superior cerebellar arteries, the thrombus extending into the right vertebral artery as far as the mid-medullary level This artery also showed several zones of incomplete obstruction in the neck. In addition there was complete obstruction of the left vertebral artery by thrombus for 2 5 cm prior to its entry into the skull and a 50% reduction of its lumen thereafter The common carotid arteries were atheromatous but not obstructed The right internal carotid artery was atheromatous and about a quarter obstructed immediately distal to its origin. The left internal carotid artery

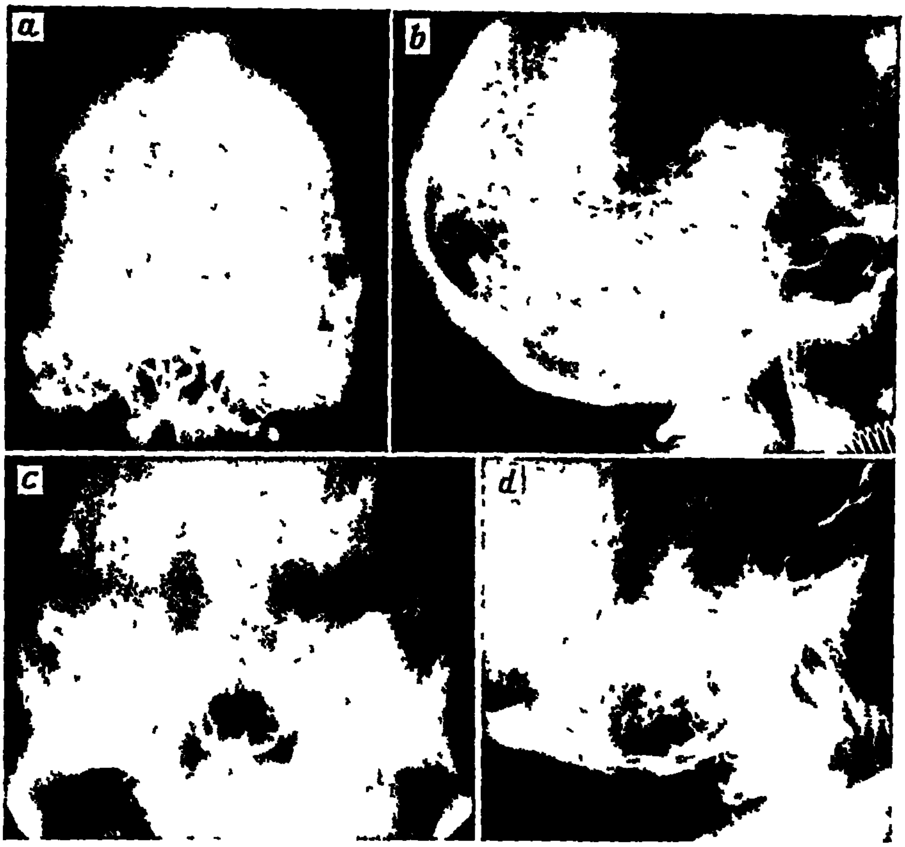

Fig 4—Vertebral angiograms: (a) normal control in anteroposterior view, (b) normal control in lateral view, (c) case 5 in anteroposterior view, showing filling of the left vertebral artery with the basilar artery reduced to a thread and its branches unfilled, (d) case 5, the same in lateral view

was almost completely obstructed just proximal to the carotid syphon The circle of Willis was complete and the posterior communicating arteries were well developed Areas of softening in the brain were of two groups, corresponding to an age of approximately seven weeks and of two days The old lesions were present in the midbrain, pons, and medulla and in both lateral lobes of the cerebellum (fig 5) There was also an area of softening in the right pulvinar, but the occipital lobes and calcarine areas were intact The recent lesions consisted of recent infarction of the cortex supplied by the left middle cerebral artery and also in that supplied by the terminal branches of the left anterior cerebral artery There was a similar area in the cortical zone supplied by the terminal branches of the left posterior cerebral artery

It would appear that this patient had for a long time been virtually dependent upon the right internal carotid and left vertebral arteries for his cerebral blood-supply and had owed his survival to his well-developed circle of Willis and posterior communicating arteries The occlusion of his basilar artery was the culminating disaster in a slowly developing sequence of events Failure of the circulation in the terminal branches of his left middle cerebral, left anterior cerebral, and left posterior cerebral arteries were terminal events in the last few days of his life

The importance of Kubik and Adams' (1946) paper lay, not so much in the fact that it described the clinical picture of fully developed basilar occlusion, though it certainly stimulated interest in it, as that, by careful retrospective correlation of the pathological findings with the history of the cases, it established that many of these patients had, for a considerable time, been having symptoms which, in the light of greater knowledge, could have led to the correct diagnosis being made before the final disaster They thus made it clear that in many cases basilar insufficiency gives rise to transitory symptoms comparable with those in carotid occlusion A similar conclusion was reached by Biemond (1951) from a careful study of 4 cases that came to necropsy

The transitory symptoms in basilar insufficiency are of a nature that might be expected to arise from momentary failure of the circulation in structures normally supplied by its pontine and medullary branches and by the posterior cerebral artery on one or both sides Commonly there are attacks of "dizziness", by which the patient usually means a feeling of faintness associated with a disturbance of balance though true vertigo may occur There may also be tinnitus or momentary loss of speech Numbness on one or both sides of the face may occur or paræsthesiæ referred to one half of the body Brief attacks of monoplegia or hemiplegia may be recorded Transitory diplopia is common Most significant of all are episodes of "dimness of vision" or "blackout" which may signify a transient hemianopia from ischæmia in the field of one posterior cerebral artery or of complete loss of vision if both are involved In association with any of these symptoms headache, sometimes severe, may be experienced Abnormal sensations referred to the abdomen may be noted Frank cerebellar symptoms are rare, presumably because of the rich anastomosis between several vessels in this organ or because of its relative insensitivity to anoxia

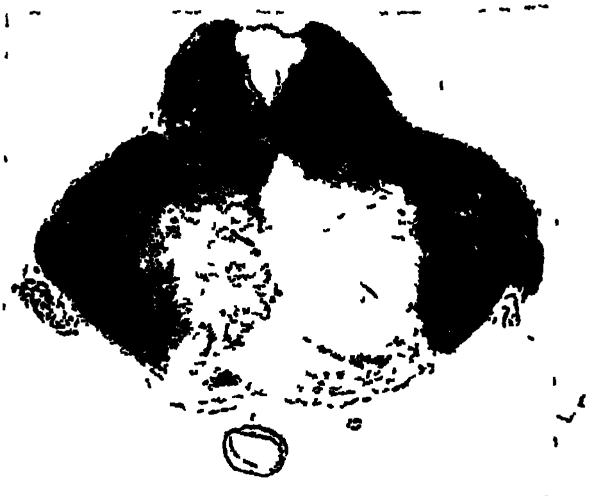

Fig 5—Case 5, showing massive softening in the central area of the pons on the left side

Case 6.—A 49-year-old master plumber, a known hypertensive and a heavy drinker who was found also to be diabetic, was admitted to hospital on account of attacks of numbness of the face over a period of four months. The first attack, occurring in a moment of annoyance, consisted of a feeling of "giddiness" with a sensation of pins-and-needles in both lips on both sides with numbness on the left side of the face, stiffening of the jaw and pulling of the tongue towards the left. He felt suddenly weak and found that he could not talk through stiffness of his tongue. When he tried to walk he staggered but there was no impairment of consciousness. In ten minutes he again felt normal. From their onset these incidents recurred at intervals varying from three days to three weeks with lessening intensity. Questioning elicited the fact that for three weeks he had experienced frequent sensations of sparkling lights passing from left to right in front of his eyes. Throughout the duration of his symptoms he had experienced severe left frontoparietal headaches.

Examination of the nervous system showed no abnormal signs. General examination showed evidence of mild diabetes, obesity, and considerable atherosclerosis. A right carotid angiogram was normal except for some increased tortuosity of arteries. A left vertebral angiogram showed normal filling of that artery, but the basilar artery was narrowed and irregular at its termination (fig. 6). The right vertebral artery was also filled and appeared irregular and narrowed. Anastomotic vessels were seen between the various cerebellar arteries. The film was interpreted as showing the presence of advanced atherosclerosis in both vertebral arteries and the basilar artery with almost complete occlusion of the right vertebral and of the basilar artery at its apex.

This patient continued to improve while in hospital and has remained well since, thus demonstrating that at least incomplete basilar occlusion may be compatible with relatively complete recovery. Numerous other examples in support of this contention might be quoted from recent hospital experience, but in the absence of arteriography or postmortem examination the diagnosis must remain presumptive. A similar view is held by Kubik and Adams (1946) and by Biemond (1951).

TREATMENT OF CAROTID AND BASILAR OCCLUSION

Management and treatment of carotid and basilar occlusion have many points in common and may be discussed briefly together.

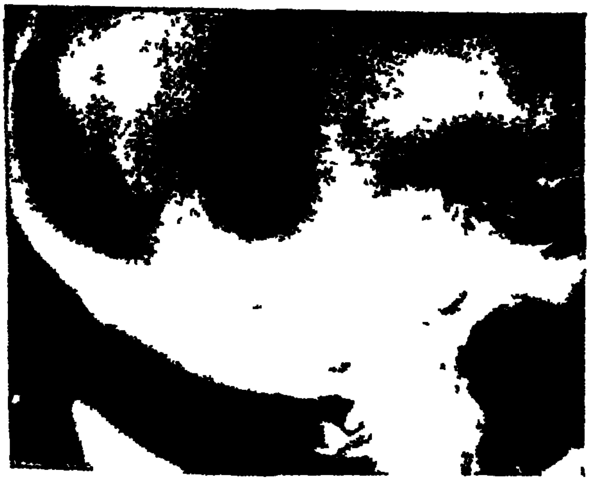

Fig. 6.—Vertebral angiogram in case 6 showing almost complete lack of contrast in the basilar artery and its branches.

In the presence of a major cerebral disaster following such an event, immediate treatment should be directed towards promoting the collateral circulation in the hope of minimising the extent of cerebral infarction. With this in view, nothing should be done to lower the systemic blood-pressure or to impair the vigour of the general circulation.

Attempts to increase the cerebral circulation have been made by the use of a variety of cerebral vasodilator procedures.

Of these, injection of the stellate ganglion or stripping of the adventitia of the carotid artery have been much advocated but are now little used, having been found to be without practical value as well as without sound physiological basis. The use of vasodilator drugs, such as papaverine and histamine, has proved of little worth, and it is notoriously difficult to increase the cerebral blood-flow by such means. The only physiological vasodilating agents are the products of metabolism, of which carbon dioxide is the most active, and the inspiration of 5% carbon dioxide in 95% oxygen for five minutes in every hour is probably the most rational way of promoting the opening up of the collateral circulation to a maximal extent.

The use of anticoagulants here, as in cases of vascular lesions involving the smaller vessels, is a matter of opinion and one requiring carefully controlled observation. When the diagnosis of carotid or basilar occlusion is established, and provided that the patient is not dangerously hypertensive, there seems to be a strong theoretical case for anticoagulant therapy. This is particularly true of cases in which transitory episodes are occurring but in which serious infarction has not yet taken place, as well as of cases due to embolism. In America the use of anticoagulants in such circumstances is certainly increasing.

In the longer-term management of cases of carotid occlusion we have nowadays to consider the possibilities of direct surgical intervention in the form of resection of a portion of the artery or of the removal of the clot followed by an attempt to re-establish the blood-flow with or without an arterial graft. Cases of this kind were reported by Strully et al. (1953), Eastcott, Pickering, and Rob (1954), and Edwards and Rob (1956).

Rob and Wheeler (1957) have recorded their experience of this procedure in 27 cases of carotid occlusion. Clearly with modern technical methods, including artificially induced hypothermia, the surgical procedure is not unduly hazardous. Satisfactory results can only be obtained before the thrombosis has extended into the intracranial portion of the artery, and as one might expect the best results are obtainable in those cases where the diagnosis has been made before irreversible changes have occurred in the brain, and particularly in cases of carotid stenosis.

This method of treatment cannot yet be applied to cases with comparable conditions in the basilar artery, but in view of the advances of the past twenty years it does not seem fantastic to hope that in due course methods may be found to overcome what at present seems an unsurmountable problem.

(The references will appear at the end of the second lecture.)

EXTRACORPOREAL CIRCULATION IN INTRACARDIAC SURGERY:

A COMPARISON BETWEEN TWO HEART-LUNG MACHINES

From Stanford University Hospital, San Francisco

IN many centres in the U.S.A. open heart surgery with the aid of heart-lung machines is undertaken almost daily. The very frequency and repetition of such operations has considerably reduced their risks, and in the less complicated cases their mortality-rate is now similar to that of other major surgical procedures.

In the pioneer stage fatalities could most often be attributed to the mechanical device. Subtle changes in the blood-clotting enzymes were common: pyrogenic surfaces, direct trauma to blood in turbulent pumps, inadequate flow or oxygenating capacity, and perhaps minute oxygen embolism all contributed to the early difficulties. But pump-oxygenators have improved, and several different models have been developed which cause less trauma to the blood and largely avoid the other difficulties. With the improved machines, the proficiency of the team has become relatively more important: their teamwork and experience begin to matter more than the choice of apparatus. Where open-heart surgery with a heart-lung machine has become a normal surgical procedure, morbidity and mortality depend chiefly on case-selection and surgical management.

At Stanford University Hospital during 1955–56 tests of several heart-lung machines established a preference for oxygenating the blood by surface filming rather than by introducing oxygen bubbles. Out of this study came the design of a machine using disposable plastic surfaces for oxygenation, in a modification of the principle advanced by Gibbon (1954). The Osborn machine (Osborn et al. 1957) was intended to have all the advantages of the Gibbon machine without its most serious disadvantage—i.e., the fact that surfaces which may be difficult to clean properly are repeatedly in contact with blood. The Osborn machine, together with a rotating-disc machine designed by Melrose (1955) at the Postgraduate Medical School of London, have been in routine clinical use since May of last year—the former throughout this period but the latter only since December. They have been operated by the same team and are at present used alternately. No particular selection of cases has been attempted save that when patients are large the Melrose machine is preferred because of its greater oxygenating capacity.

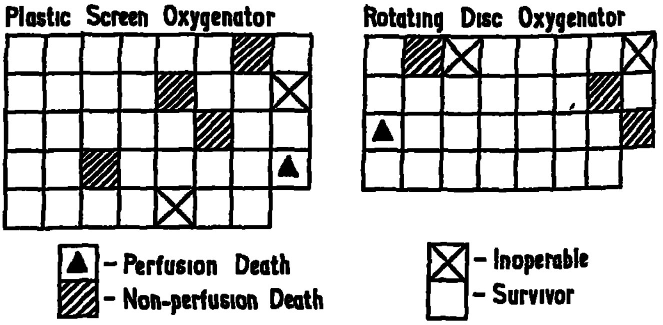
From a study of the 100 cases operated on during this time, no substantial difference in mortality or morbidity or any other measurable variable could be detected. As technique developed with experience, each machine could be expected to provide an entirely satisfactory operative environment, and the choice between them could thus be made only on grounds of convenience, cost per perfusion, and other administrative considerations.

On such grounds it has been decided to adopt the Melrose machine with an important change in its construction, so that all substantial parts in contact with blood may be made disposable and that they may be sterilised by autoclave. The oxygenator is to be of metal covered with 'Teflon', and disposable discs of stainless steel replace those now made of plastic. These requirements are judged essential for the proper maintenance and safety of an apparatus used more than five times a week. With this alteration, it is hoped that from now onwards this machine can be used for all intracardiac operations at Stanford University Hospital which require extracorporeal circulation of the blood.

Results of Operations

During the comparison of the two machines, 70 patients, in age between 4 months and 52 years and varying in size between 0·26 and 2·0 sq. metres, were operated on (table I). While the majority were in good health, there was no rigid exclusion of those not so fortunate: 3 were in heart-failure, 6 were undergoing a second or third thoracotomy, and pulmonary disease was present in several, as was marked cyanosis, which was extreme in 2. Though the acceptance of bad-risk patients is necessary, proper perspective is obtained only if, in the initial experience, they are interspersed with those offering a good chance of cure.

In presenting the results (see figure), we have followed a format used by Kirklin et al. (1958), and like them have attempted to attribute to each death its true cause. Where no satisfactory clinical or pathological justification for the death was found, it was attributed to the perfusion. Some deaths have occurred in patients found to have lesions which defied correction. In the remainder, a review of the clinical course and necropsy findings showed sufficient cause to exonerate the perfusion. The figure shows this analysis. The mortality in this series is better than 19%, and when inoperable cases are excluded it is better than 13%.



The inoperable problems were a tumour of the left ventricle, the removal of which left too little muscular tissue to support life, 2 single ventricles which could not be anatomically divided and total anomalous pulmonary venous return in an infant. One of the 2 deaths attributed to perfusion was in a patient with an interventricular septal defect and moderate pulmonary hypertension. The other was in a patient with the tetralogy of Fallot who was markedly cyanotic. In neither could a satisfactory reason be given for their demise, one eighteen hours after operation and the other on the third postoperative day.

Among the causes found for failure in the remainder have been cardiac tamponade due to inadequate venting of the pericardium and retrosternal space, ineffective blood replacement during the postoperative period, and, in 1 case, massive infarc-

TABLE I—DISTRIBUTION BY ANATOMICAL DIAGNOSIS

—	No. of cases	No. surviving
Interventricular septal defect	20	17
Tetralogy of Fallot	14	11
Single ventricle	2	0
Interatrial septal defect (with associated conditions)	18	18
Left-ventricular/right-atrial shunt	5	5
Common atrioventricular canal	1	1
Total anomalous pulmonary venous return	1	0
Pulmonary stenosis	4	4
Pulmonary stenosis with atrial septal defect (cyanotic)	2	0
Mitral insufficiency	1	0
Left atrial tumour	1	1
Left ventricular tumour	1	0
Total	70	57

TABLE II—AVERAGE PLATELET-COUNT IN THOUSANDS

Before bypass	234	217
After bypass	144	130
One hour after bypass	175	165

tion of the right ventricle due to interference with its blood-supply. Heart-block has undoubtedly contributed in 2 instances but has not in itself been the reason for death. The presence of an unsuspected patent ductus arteriosus, in a patient operated on for interventricular septal defect, contributed to another failure. In this instance, equal pressures obtained both in the aorta and in the pulmonary artery which was enormously dilated.

Pulmonary complications have been little in evidence, and, save in the patient whose left ventricle, after the removal of a tumour, was deficient in muscular tissue, we have not been plagued by pulmonary œdema or abnormal bronchial secretions. Respiratory embarrassment occasioned by the thoracotomy has been greatly reduced by using the median stenotomy incision (Gerbode et al. 1958), and little difficulty attends convalescence on this score. We have noted, however, temporary respiratory acidosis when nursing care has not sufficiently encouraged breathing.

Post-perfusion Syndrome

We have not encountered "the syndrome of sudden death": no patient whose immediate postoperative condition was satisfactory deteriorated unexpectedly. More familiar has been a "post-perfusion syndrome", characterised by a persistent hypotension of mild degree, by restlessness and hyperpyrexia, and by mild cyanosis associated more obviously with the poverty of the peripheral circulation rather than with any respiratory cause. Review of the course of operation in the 5 patients with this syndrome has underlined the hypotensive element. Each was hypotensive during anæsthesia and surgery, even before perfusion was started. Neither blood-transfusion nor vasoconstrictor drugs had more than a temporary effect at this time.

During the period of perfusion, in spite of a perfusion-rate known to be adequate (2·3 litres per sq. m. per minute) the systolic blood-pressure remained below 70 mm. Hg and could not be raised by increasing the flow-rate. After perfusion the hypotensive state persisted. Errors in restoration of blood-volume were unlikely because the patients were accurately weighed after operation. 2 patients with this syndrome failed to survive and are classified as perfusion deaths, 2 others whose death is put down to surgical causes showed essentially similar signs; in another, these signs were of milder degree and progressively diminished, leading to full recovery. All were patients in whom considerable surgical correction was required, all had extensive refashioning of the pulmonary-outflow tract and each had a considerable return of blood from the open heart through bronchial-artery anastomoses. This latter problem is regarded as important, for blood collected from the open heart must undergo additional trauma, and embolism with air rather than with oxygen will be possible on its return to the extracorporeal circuit. That it should be returned is perhaps debatable, but certainly this is essential in all cases where such collaterals are prominent. It has been our policy to let such blood settle in a reservoir for as long as possible before returning it to the perfusion.

Elective Cardiac Arrest

Elective cardiac arrest with potassium citrate (Melrose et al. 1955) has been used routinely for defects involving the interventricular septum and whenever blood-loss has been excessive or has prevented a good view of the operative field. In this series, it has been used on 36 occasions. 2 patients have undergone repair of an interventricular septal defect twice, and on each occasion cardiac arrest was used. With necessary precautions (Gerbode and Melrose 1958) it is established that it is helpful, reliable, and safe.

The Hæmatology of Perfusion

Postoperative hæmorrhage has not been a problem, the average loss of blood being 890 ml. with extremes of 80 ml. and 4050 ml. 3 patients were reopened for such bleeding, and in 1 an obvious focus was found in the cardiotomy wound. The 2 others had undergone open heart surgery within the previous six weeks and both oozed considerably at the successful second operation. In each case evacuation of blood clots was followed by little further bleeding and full recovery.

Coagulation abnormalities have been slight and have required no unusual management. In routine investigations the following observations were made by one of us (H. A. P.).

In an attempt to compare the effect of the two types of pump oxygenators on the circulating blood, changes were followed in the levels of plasma-hæmoglobin, blood platelets, fibrinogen, and other plasma-coagulation factors. During the early part of this study, all the donor blood was approximately four hours old. More recent bypasses used blood collected twenty-four hours in advance. There was no difference in the hæmatological changes induced that could be ascribed to the age of the donor blood.

Fibrinogen loss, which was an important source of clotting difficulties with early experimental pump oxygenators (Osborn et al. 1956), did not occur with either the Osborn or the Melrose machine.

Platelet loss during the bypass occurred to the same degree with both (table II)—never to levels low enough to be responsible for hæmorrhage. After operation, the counts returned rapidly towards the control values in all but 2 cases, in both of which an unusual amount of bank blood had been given during the postoperative period because of surgical difficulties in securing adequate hæmostasis.

Plasma-hæmoglobin levels over 50 mg. per 100 ml. were unusual with either machine. Nor in most cases, could changes be detected in clotting-times, prothrombin-times, prothrombin-consumptions, or thromboplastin-generations. In a few cases, more pronounced rises in plasma-hæmoglobin, and definite changes in plasma-coagulation factors (especially those involved in the first stage of coagulation), did occur. These changes were correlated with the length of the bypass—and particularly with the amount of blood returned to the machine by suction from the interior of the heart—not with the type of machine used.

In no cases did a postoperative coagulation defect become a serious problem in management Proper heparin neutralisation was ensured by a protamine titration technique (Perkins et al 1956) Defects in plasma-coagulation factors (manifest most commonly by defective prothrombin-consumption) proved to be spontaneously reversible in a few hours, requiring no therapy beyond replacement of blood as it was lost In cases requiring more than the average amount of blood postoperatively, persistent thrombocytopenia was prevented by using fresh plastic bag or siliconed bottle blood (Jackson et al 1956)

Electrolyte Balance

We have noted only minor changes in the serum-electrolytes and have not regarded these as significant Although a slight acidosis and lowering of the carbon-dioxide content has been observed in the postoperative period, it has only very rarely needed correction A slight increase in the lactic-acid content of the blood has also occasionally been found, but this can be accounted for by accumulation of lactic acid in the blood used to charge the machines

Conclusions

Few surgical groups have had the opportunity of comparing two heart-lung machines used concurrently in clinical practice At Stanford University Hospital such a comparison has underlined not the differences but the similarities between two machines very different in design Each is capable of imitating closely the normal cardiac output and of providing adequate gas exchange even for a large man Neither has occasioned significant alterations in either the chemistry or the constituents of the blood and no untoward coagulation difficulties attend their use As an outcome of this comparison it has become possible to decide on one machine, and, for reasons of convenience, cost, and ease of management, an apparatus utilising modified Melrose rotating-disc oxygenator is to be substituted for the present instruments

Our experience lends support to the view that to improve the outlook for open heart surgery, improvement in team skill is more important than improvement in mechanical design Until a disposable closed-circuit pump oxygenator of membrane type has been fully tested and has been proved to have the outstanding advantages it promises, present requirements can be adequately met with existing machines We are convinced, however, that the most satisfactory clinical course follows the perfusion that most nearly maintains homœostasis, and that the machine chosen should be able to do this in all circumstances

A remarkable benign and uneventful postoperative picture is presented by most of those now undergoing such surgery The use of the median stenotomy incision rather than a bilateral thoracotomy decreases operating time considerably, and it is rare indeed for such a case to take more than three hours This reduction in operating time has proved as beneficial in intracardiac surgery as in any other branch

SINCE tobacco amblyopia was first described by Beer (1817) there has been much discussion about its ætiology By definition tobacco is a necessary factor, but why should only a few people who smoke get this amblyopia? We attempt to answer this question

Tobacco amblyopia is commonest in middle-aged males Traquair (1930) found extremes of 23 and 84 years and only 7 females in 1525 cases The amount of tobacco smoked varies considerably Usher (1927) and Traquair (1930) found an average weekly consumption of 3 oz, with extremes of $^1/_2$ oz and 9 oz Tobacco amblyopia usually affects persons who smoke strong pipe tobacco, cigars and cigarettes are seldom responsible. Most patients have smoked for many years Nettleship (1887) found symptoms developing after a minimum of a year's smoking

It is generally accepted that excessive consumption of alcohol tends to increase the incidence and severity of tobacco amblyopia

Many workers have recognised the importance of the nutrition and general health of the patient (Mackenzie 1854, Traquair 1930, Greeves 1946, Evans 1946, Schepens 1946) It has been suggested that a deficiency of one or more members of the vitamin-B group may be an ætiological factor, and the response to vitamin-B complex and yeast has been studied (Shattuck 1928, Minot 1929, Carroll 1944), but these clinical trials have not convincingly shown that it is deficiency of vitamin-B complex that is the cause of tobacco amblyopia In many cases smoking had been stopped, this alone improves most cases Often the diet and drinking habits of the patients had been altered, and it is now known that yeast contains a small quantity of vitamin B_{12} (Peeler et al 1951)

Duke-Elder (1954) noted that the injection of large doses of vitamin B_{12} was effective in tobacco amblyopia, even if smoking was continued It was therefore decided to determine whether tobacco amblyopia could be regarded as one of the clinical manifestations of vitamin-B_{12} deficiency

Method

In this series the criteria on which the diagnosis of tobacco amblyopia was based were as follows

(1) The patient must be a smoker

(2) A centrocæcal scotoma must be present

(3) This scotoma must be horizontally oval, with a sloping edge and most easily detected by a reduced stimulus—i e , with a red or a small white test object

(4) The scotoma must be bilateral, though not necessarily equal on the two sides

(5) The defect for colour must exceed that for white

(6) There must be definite nuclei within that scotoma on the horizontal meridian

(7) An impairment of the temporal colour field must exist within the 30° circle (In the more advanced cases a similar defect is also seen to a small white test object)

The visual fields were investigated by one of us only (A J A M) to ensure uniformity of technique

During a twelve-month period 14 male patients with tobacco amblyopia were seen by us at the Bristol Eye Hospital A history was taken from each patient and a complete clinical examination made In addition each patient underwent a full blood examination, gastric analysis, liver-function tests, and measurement of the serum-vitamin-B_{12} level It was also decided that biopsy of the sternal marrow should be undertaken in every patient with histamine-fast achlorhydria and evidence of neurological involvement, irrespective of whether or not anæmia was present

A summary of the clinical and pathological findings in 14 cases of tobacco amblyopia and the response to treatment with cyanocobalamin is included in the accompanying table

Results

Anæmia

The hæmoglobin level was less than 90% in 3 of the 14 patients with tobacco amblyopia

2 of these patients (cases 1 and 2) had histamine-fast achlorhydria and a megaloblastic marrow and therefore could be described as having the retrobulbar neuritis of addisonian pernicious anæmia

Case 1—A man, aged 62, was initially seen at the Bristol Eye Hospital in June, 1956, with three months' history of failing vision His visual acuity was right 6/24, left 6/18, and the fields were typical of tobacco amblyopia He was advised to stop smoking immediately and was given oral vitamin B_1 In spite of this his vision slowly deteriorated

CLINICAL AND PATHOLOGICAL FEATURES IN 14 MEN WITH TOBACCO AMBLYOPIA

Case no	Age (yr)	History of smoking (yr)	Visual acuity		Histamine fast achlorhydria	Hb (%)	Blood-picture	Serum bilirubin (mg per 100 ml)	Glossitis	Neurological involvement *	Serum-vitamin-B_{12} level (µµg per ml)	Visual acuity after smoking stopped and oral vitamin-B complex given		Visual acuity after parenteral vitamin B_{12}		Remarks
			Rt	Lt.								Rt	Lt.	Rt	Lt

14	67	50+	6/60	Hand movements only	Free acid	104	Normal	1·35	—	—	Not done			6/36	Hand movements only	Stopped smoking and given vitamin B_{12}, visual fields returned to normal in 2 mos, advanced senile cataracts

* Neurological involvement, see text for full details

† Serum-alkaline-phosphatase 16 King-Armstrong units per 100 ml, serum-globulin 3·3 g per 100 ml

In March, 1957, he was admitted with three months' history of soreness of the tongue, slurring of speech, and numbness and paræsthesiæ in both legs. His visual acuity was right 6/60, left 2/60. The fields were now difficult to map accurately owing to poor fixation but showed a large centrocæcal scotoma to 3/1000 white on the right and to 15/1000 white on the left, with gross depression of the temporal fields to 15/1000 red. The tongue was smooth and red at the edges. There was impaired sensation to pinprick in both legs below the knees and diminished sense of position and vibration in the feet.

The hæmoglobin level was 86%, the serum-vitamin-B_{12} level was 15 μμg per ml. Parenteral administration of cyanocobalamin 100 μg daily for fourteen days followed by 100 μg twice a week produced a dramatic improvement in the vision. Two months after treatment had been started the visual acuity was right 6/24, left 6/12, and the patient now had classical tobacco-amblyopia fields. His vision in both eyes improved to 6/12 in three months and 6/9 in six months.

Comment.—It seems reasonable to suggest that the tobacco amblyopia in case 1 can be regarded as a clinical manifestation of vitamin-B_{12} deficiency. The deterioration of vision and the defect in the visual field preceded the onset of anæmia, glossitis, and neurological involvement by more than nine months. The excellent response to parenteral vitamin B_{12} further supports the view that a combination of the toxic effect of tobacco on the retina and the low serum-vitamin-B_{12} level produced tobacco amblyopia.

Case 2.—A man, aged 75, was admitted to Southmead Hospital in August, 1956, under the care of Dr. J. A. Birrell with pernicious anæmia. He was treated with 'Anahæmin', and on discharge his hæmoglobin had increased from 33 to 70%.

In February, 1958, he attended the Bristol Eye Hospital with four weeks' history of failing vision. He had started smoking a pipe sixteen months previously. His visual acuity was 6/60 in each eye, and he had tobacco-amblyopia fields. No other abnormal physical signs were present. For the past eighteen months he had been having anahæmin 2 ml. twice weekly. His hæmoglobin level was now 93% and serum-vitamin-B_{12} level 130 μμg per ml. He was given parenteral cyanocobalamin 100 μμg twice weekly and allowed to continue smoking; within two months his vision had improved to right 6/12, left 6/9.

Comment.—It is evident that, in this known case of treated pernicious anæmia, vitamin-B_{12} deficiency was not sufficient to produce anæmia or signs of peripheral neuropathy or spinal-cord involvement. However, as in case 1, it seems reasonable to presume that the retina had been made unduly sensitive to vitamin-B_{12} deficiency. This hypothesis is supported by the knowledge that there was no amblyopia when the patient was very anæmic (Hb 33%), and at that time he was a non-smoker.

In case 3 neurological features suggesting vitamin-B_{12} deficiency were present, but there was free acid in the gastric juice, biopsy of the marrow showed normoblastic erythropoiesis, and there was biochemical evidence of liver dysfunction.

Case 3.—A man, aged 81, had six months' history of progressive deterioration of vision. For about two months he had had a sore tongue, numbness and tingling in his hands and feet, weakness of his legs, and difficulty in walking.

On examination his visual acuity was right 6/24, left 6/18, and the fields were typical of tobacco amblyopia. His tongue was red and smooth. His gait was a little unsteady. He had a definitely weak grip and some loss of power in both legs. Stocking anæsthesia to light touch and pinprick was present in both legs below the knees, and their sense of position and vibration was impaired. The knee-jerks were diminished, the ankle-jerks absent, and the plantar responses flexor. The hæmoglobin was 89%. A blood-film showed normocytic normochromic blood with anisocytosis and poikilocytosis. Gastric analysis revealed free acid, and the marrow was normoblastic. The serum-bilirubin level was 2.75 mg. per 100 ml. and the serum-vitamin-B_{12} level 300 μμg per ml. The Wassermann reaction was negative.

Comment.—Case 3 had clinical manifestations of vitamin-B_{12} deficiency: glossitis, peripheral neuropathy, and involvement of the posterior spinal column. Within two months of parenteral administration of cyanocobalamin the visual acuity had improved to 6/9 in both eyes and the fields had become normal. This dramatic response can be entirely attributed to cyanocobalamin because the patient continued to smoke as heavily as before throughout the course of treatment.

Neurological Involvement

Clinical evidence of peripheral neuropathy, spinal-cord involvement, or encephalopathy was present in 5 of the 14 cases. Case 1 had pernicious anæmia. In case 4 the clinical picture strongly suggested subacute combined degeneration of the cord, but unfortunately the patient refused permission for full investigation and has repeatedly failed to attend for follow-up examination.

In the remaining 3 patients with neurological features suggesting vitamin-B_{12} deficiency gastric analysis revealed free acid. The findings of peripheral neuropathy and involvement of the posterior column in case 3 have already been reviewed. In case 5 there was six months' history of paræsthesiæ in both legs below the knees, but no abnormal signs were detected. The presentation of tobacco amblyopia and mental changes (acute depression, irritability, and failing memory for two months) in a non-anæmic patient (case 6) is of particular interest. Although free acid was present in the gastric juice, the serum-vitamin-B_{12} level was exceptionally low (15 μμg per ml.) and liver-function tests showed a raised serum-bilirubin level.

Glossitis

A sore red smooth tongue was observed in 4 of our 14 patients. In 2 of these 4 the hæmoglobin level was below 90%; case 1 had pernicious anæmia, and case 3 had free acid and a normoblastic marrow. The 2 non-anæmic patients were forbidden to smoke and were initially given oral vitamin-B complex. This regime apparently produced no improvement in the state of the tongue. Treatment with cyanocobalamin caused complete subjective and objective improvement in the glossitis in all 4 patients.

Serum-vitamin-B_{12} Levels

The serum-vitamin-B_{12} levels were estimated by microbiological assay with *Euglena gracilis* var. *bacillaris* as test organism (Mollin and Ross 1952, 1954). With this method Mollin and Ross found that the normal range for serum-vitamin-B_{12} levels was 100–900 μμg per ml., with a mean value of 360 μμg per ml. The levels obtained in our patients with tobacco amblyopia were compared with those of a control group of healthy persons matched for sex and age.

In 13 patients with tobacco amblyopia the serum-vitamin-B_{12} levels ranged from 15 to 350 μμg per ml., with a mean value of 218 μμg per ml. The values for 12 controls ranged from 280 to 1000 μμg per ml., with a mean value of 538 μμg per ml. The difference in the serum-vitamin-B_{12} levels between the patients and the controls appears highly significant ($P<0.01$), according to the distribution-free type of test function used (the X-test by Van der Waerden). There is no significant difference in age between the two groups by the same test function.

Treatment with Cyanocobalamin

Most cases of tobacco amblyopia improve when the patient stops smoking, and many cases even when smoking is only reduced. In our series cases 11 and 12 were completely cured in this way, and 4 patients cases (6, 9, 10, and 13) were clinically cured although slight signs of tobacco amblyopia remained in their fields.

This method of treatment has disadvantages: it is irksome to the patient, and the recovery-rate varies. In 170 cases Griffith (1887) found an average recovery period of seventeen months, with extremes of three and forty-two months. In our small series case 11 recovered in three months, whereas case 7 had not recovered after seventeen months. Rarely the vision may deteriorate, as in case 1 and in 4% of Griffith's (1887) cases.

We gave cyanocobalamin to 9 patients, of whom 3 continued smoking as heavily as before. All recovered more rapidly than would have been expected with the prohibition of smoking and oral vitamin-B complex alone, 6 patients had initially had this orthodox treatment. Parenteral cyanocobalamin 100 μg. was first given once or twice weekly for a month (once a day for the first fourteen days to our anæmic patients), then every fortnight for two months, and finally at intervals of a month. Probably it is safe to stop treatment after six months, provided that the fields are normal and there is no evidence of addisonian pernicious anæmia or neurological involvement. Our experience in this clinical trial suggests that much larger doses of cyanocobalamin would have been even more rapidly effective.

Discussion

Tobacco Amblyopia, Vitamin-B$_{12}$ Deficiency, and Histamine-fast Achlorhydria

Gastric analysis revealed histamine-fast achlorhydria in 9 of 15 patients with tobacco amblyopia described by Leishman (1952) and in 8 of 13 cases in the present survey. In these 8 cases the serum-vitamin-B$_{12}$ levels ranged from 15 to 350 μμg. per ml., with a mean value of 208 μμg. per ml.

Histamine-fast achlorhydria is an essential feature of addisonian pernicious anæmia and may precede the onset of anæmia by many years (Hurst 1922, Meulengracht 1925). Callender and Denborough (1957) produce evidence that there is a "pre-pernicious-anæmia" state in which there is achlorhydria with gastric atrophy, poor absorption of vitamin B$_{12}$ corrected by intrinsic factor, and a low or a low normal serum-vitamin-B$_{12}$ level without symptoms of anæmia. 2 of Leishman's (1952) patients and 1 of ours (case 1) developed tobacco amblyopia many months before they were found to have pernicious anæmia. In view of this it seems likely that they were in the "pre-pernicious anæmia" state at the time. One of the manifestations of this state might therefore be tobacco amblyopia. Callender and Denborough refer to the inheritance of pernicious anæmia and the "pre-pernicious-anæmia" state. Nettleship suggested that tobacco amblyopia might have a genetic basis.

Mollin and Ross (1954) have shown that a critical level for vitamin-B$_{12}$ deficiency is 100 μμg. per ml., and that above this level in the serum the marrow is normoblastic. Because a level of 100 μμg. per ml. is a critical level for the marrow, it does not necessarily follow that the same applies to the retina poisoned by tobacco. It may well be that about 250 μμg. per ml. is the critical level of serum-vitamin-B$_{12}$ for the development of tobacco amblyopia. The level of free vitamin B$_{12}$ in the serum might also be important in this context because presumably it is only the free vitamin B$_{12}$ that can be immediately used by the retina. Unfortunately we could only estimate the level of total vitamin-B$_{12}$ in the serum.

In view of the fact that 2 of our patients (cases 1 and 2) with tobacco amblyopia and 10 of 75 cases reviewed by Leishman (1952) were found to have pernicious anæmia, we decided to review the published cases of retrobulbar neuritis in pernicious anæmia (Cohen 1936, Box 1936, Hine 1936, Talbot 1936, Kampmeier and Jones 1938, Turner 1940, Benham 1951, Nelson and Weaver 1956).

A survey of these case-reports suggests that many of these patients with pernicious anæmia could be described as having tobacco amblyopia. Of 15 patients 9 were specifically reported as being smokers and 14 were males, yet the proportion of males to females in pernicious anæmia is usually given as 1 : 3. One of the characteristics of British and American males is that they tend to smoke pipes and cigarettes more than do females. Unfortunately most of the fields reported were incomplete, the central fields were not always recorded, and only Benham (1951) used a red object. However, centrocæcal scotomata were found in 6 cases, which suggests tobacco amblyopia. Turner (1940) noted that the development of amblyopia was not related to the degree of anæmia or to neurological involvement. Possibly it is related to the smoking habits of the patient, the retina being unduly sensitive to tobacco owing to vitamin-B$_{12}$ deficiency. In retrobulbar neuritis of pernicious anæmia the histological findings in the optic nerves (Bickel 1914) appear to be similar to those observed in tobacco amblyopia (Duke-Elder 1954).

Vitamin-B$_{12}$ Deficiency in Liver Dysfunction

Since free acid was present in the gastric juice in 5 of 13 patients with tobacco amblyopia in our series and in 9 of 15 patients in Leishman's (1952) series, it is evident that addisonian pernicious anæmia or the "pre-pernicious-anæmia" state cannot be regarded as the only condition predisposing to the development of tobacco amblyopia.

In our 14 cases there was no history or clinical evidence of liver disease in any patient. However, it is well known that portal cirrhosis may remain latent for many years, and that its incidence increases with age. Rolleston and McNee (1929) and McCartney (1933) reported that 52·1% and 35% of cases of cirrhosis of the liver found at necropsy had no history, symptoms, or signs of liver disease during life. In this clinically latent group even liver-function tests may be completely normal (Hetzel 1950).

In 6 of the 14 patients with tobacco amblyopia liver-function tests indicated some abnormality. There was a slight increase in the serum-globulin and serum-alkaline-phosphatase levels in 1 patient and a raised serum-bilirubin level in 5 patients. If the normal serum-bilirubin level is accepted as being 0·62 ± 0·25 mg. per 100 ml. (Schilling and Harris 1952), the serum-bilirubin levels were high in 5 cases (2·75, 1·8, 1·35, 0·95, and 0·9 mg. per 100 ml.). Both De Schweinitz and Edsall (1903) and Greeves (1946) also found evidence of liver dysfunction in some of their patients with tobacco amblyopia. In our two proved cases of addisonian pernicious anæmia the liver-function tests were normal, and similar findings were reported in 19 of 20 patients with untreated pernicious anæmia described by Schilling and Harris (1952).

Swendseid et al (1957) found that, in cirrhosis, there is a greatly reduced level of vitamin B_{12} in the liver, the average value being 26 µg per 100 g, whereas in healthy people of all age-groups there is an average of 70 µg per 100 g. of wet tissues Probably, therefore, in some cases of tobacco amblyopia there is a low level of vitamin B_{12} in the liver

Vitamin B_{12} exists in the serum both free (when it can be utilised by the tissues) and bound to α-globulin It has been shown (Lear et al 1954, Jones and Mills 1955, Rachmilewitz et al 1956, Mackay et al 1957) that, in hepatic cirrhosis, there is a rise in the level of bound vitamin B_{12} and often a fall in that of free vitamin B_{12} in the serum and an increased urinary excretion of what is apparently free vitamin B_{12} In a case of obstructive hepatic necrosis described by Mackay et al (1957) very high levels of bound vitamin B_{12} were found in the serum It is suggested that, in some cases, the liver releases a binding protein with a high avidity for vitamin B_{12} which would "mop up" any available free vitamin B_{12} and hold it in the blood-stream If this were so, we suggest that there might be less free vitamin B_{12} available to the retina and hence, if the patient was a heavy cigarette smoker or a pipe smoker, an increased liability to tobacco amblyopia

In view of these findings and suggestions it is unfortunate that the levels of free vitamin B_{12} in the serum of our patients with tobacco amblyopia could not be measured In our 6 patients with abnormal liver-function tests the levels of total vitamin B_{12} in the serum ranged from 15 to 300 µµg per ml, with a mean value of 213 µµg The mean value in our healthy controls was 538 µµg per ml

Low Serum-vitamin-B_{12} Levels in Dietary Deficiency

It is well recognised that the serum-vitamin-B_{12} levels may be very low after partial or total gastrectomy and in association with the "blind loop" and malabsorption syndromes, diverticulosis of the small intestine, and treatment with anticonvulsants (Spray and Witts 1958) Friedenwald (1953) has also shown that diabetics have a tendency to vitamin-B_{12} deficiency, this then may explain the increased incidence of tobacco amblyopia in diabetics Low serum-vitamin-B_{12} levels have also been reported in "vegans" who cannot absorb normal amounts of this vitamin Badenoch (1954), Harrison et al (1956), and Spray and Witts (1958) have described megaloblastic anæmia due to dietary deficiencies A dietary deficiency of vitamin B_{12} may be present in some elderly men, particularly if they live alone This deficiency might be expected to predispose towards the development of tobacco amblyopia long before producing megaloblastic anæmia or evidence of neurological involvement The increased severity and frequency of tobacco amblyopia which Schepens (1946) found among mal-nourished Belgians could be explained in this way Some of the complicated changes in the visual field of prisoners-of-war in the Far East may be due to a combined deficiency of vitamin B_1 and vitamin B_{12}, the former causing the central, and the latter, combined with smoking, causing the centrocæcal part of the scotoma (Livingston et al 1946)

Conclusions

We have presented evidence that, in persons with even mild vitamin-B_{12} deficiency, the retina or the optic nerve is unduly sensitive to tobacco

In a study of 13 patients with tobacco amblyopia the vitamin-B_{12} levels in the serum ranged from 15 to 350 µµg per ml These values differed significantly from those obtained in healthy controls, the mean level in our patients being 218 µµg per ml and that in the controls 538 µµg per ml

Other clinical manifestations of vitamin-B_{12} deficiency may be absent because, in pipe smokers and in heavy smokers of cigarettes, the amblyopia may precede the onset of anæmia, glossitis, neurological involvement, or megaloblastic bone-marrow by months or even years

We have also produced evidence that tobacco amblyopia and the retrobulbar neuritis of addisonian pernicious anæmia may be one and the same condition

An important additional finding is that, in 2 of our patients, tobacco amblyopia and neurological features suggesting vitamin-B_{12} deficiency were associated with free acid in the gastric juice, abnormal liver-function tests, and low serum-vitamin-B_{12} levels

We therefore suggest that, in any case of unexplained peripheral neuropathy, myelopathy, or encephalopathy, especially if it is considered to be due to nutritional deficiency, the levels of total and of free vitamin-B_{12} in the serum should be measured, even if histamine-fast achlorhydria is not present

Gastric analysis revealed free acid in 5 of 13 patients, and in 6 of 14 there was biochemical evidence of liver dysfunction

In this limited clinical trial the effect of parenteral cyanocobalamin in improving visual acuity and completely reversing the changes in the visual field has been most encouraging, even if the use of tobacco is continued

We thank the consultants of the Bristol Eye Hospital for permission to study and treat their patients, Miss A Sinclair Rose, of the Public Analyst's Department, Canynge Hall, Bristol, for the microbiological assays, Dr G Herdan for the statistical analysis of our results, Mr F C E Rooke, charge-nurse, for help, and Dr C C Ewing for criticism

MALIGNANT RENAL HYPERTENSION (WILSON-BYROM SYNDROME) CURED BY NEPHRECTOMY

Charles N Peabody
M.D Harvard
Donald C Gates
M.A Cantab, M.D Harvard
From the Veterans Administration Hospital, Providence, R I

It was predicted by Goldblatt (1948) that there would be many mistakes in the application to man of his classical experiments on renal hypertension in rats He did not mean that constriction of a main renal artery was the cause of all hypertension in man but that the experimental application of his clamp would exactly reproduce the physiological state of the kidney in essential hypertension He considered his experimental method to be the best suited to effect a state of abnormal physiology analogous to that caused by arteriolar sclerosis in the kidney—namely, reduction of intraglomerular capillary pressure and reduction of blood-flow to the nephron

Wilson and Byrom (1939) described a type of malignant hypertension in rats that apparently had its origin in reduced renal blood-flow During the next fifteen years they retested their theory, received confirmation from Blacket and Sellers (1951), and outlined (Wilson 1953) a syndrome of hypertension in rats which has the following clinical and pathological features

(1) Hypertension is produced by artificial stenosis of the main renal artery to one kidney, the artery to the other kidney remaining intact

(2) Encephalopathy eventually develops, often without uræmia

(3) The resulting hypertension produces extrarenal vascular lesions closely resembling those seen in human malignant hypertension in all organs except the kidney supplied by the stenosed artery

(4) Prompt removal of the kidney made ischæmic by the stenosis usually relieves the hypertension and is followed by disappearance of the encephalopathy

(5) Histologically the excised kidney and its stenotic artery reveal no abnormality

We report the following case for several reasons the pathological findings responsible for the hypertension closely parallel Goldblatt's original experimental method, clinical and laboratory data were collected both before and after operation, and strong support is given to the suggestion that malignant hypertension may be due to renal factors

Case-report

A weaver, aged 56, was admitted to this hospital on March 5, 1954, with several months' history of hypertension His family doctor first diagnosed hypertension in June, 1953, when the patient's blood-pressure was 210/110 mm Hg and nothing abnormal was found in his urine Treatment with 'Metamine' (triethanolamine trinitrate biphosphate) was instituted A few weeks later the patient had an attack of epigastric pain, hæmatemesis, and bitemporal headache In December, 1954, his blood-pressure was 224/110 mm Hg, and rales heard in his chest suggested a low-grade pulmonary infection Albuminuria had also appeared Antibiotics and digitalis procured the patient some benefit

On admission to this hospital his blood-pressure was 216/130 mm Hg in his right arm and 260/160 mm Hg in his left His cervical veins were distended He had a conjunctival hæmorrhage, grade-IV retinopathy, papillœdema, and flame-shaped retinal hæmorrhages His vision was much impaired. His heart was enlarged to percussion, and the edge of his liver was tender and palpable 8 cm below his costal margin His peripheral pulses were strong His lungs were emphysematous but free from rales

Investigation showed hæmoglobin 12 g per 100 ml, white blood-cells 15,300 per c mm, erythrocyte-sedimentation rate 28 mm in 1st hour (Westergren) and urine sp gr 1 029, copious albumin, blood-urea nitrogen 22 mg per 100 ml The phenolsulphonphthalein test showed that 10% of the dye was excreted in the first 15 minutes and 25% after 2 hours The retention of bromsulphalein was 20% Radiography of the chest showed that the heart was enlarged transversely with prominence of the left ventricle and calcification of the aortic knob The vascular markings of the lungs were consistent with early pulmonary congestion Intravenous pyelography showed an enlarged right kidney with good concentration of the dye, whereas the left kidney could not be seen at all There was calcification of the abdominal aorta and the iliac vessels Electrocardiography showed left ventricular strain Retrograde pyelography showed normal renal architecture bilaterally, but indigo-carmine injected intravenously was not excreted from the left kidney The arm-to-tongue circulation-time was prolonged by 31 seconds Lumbar puncture produced cerebrospinal fluid (C S F) under a pressure of 216 mm H_2O and containing protein 150 mg per 100 ml 'Regitine' reduced the blood-pressure from 254/150 to 210/110 mm Hg

Treatment and progress—Clinically the patient became rapidly worse while being observed under the customary treatment On the ninth day after admission his condition was desperate, and he lapsed into semicoma with Cheyne-Stokes respiration Lumbar puncture produced C S F under a pressure of 340 mm H_2O, and the electroencephalogram was very abnormal 50% glucose intravenously, hexamethonium, and hydrallazine were administered to improve his condition for surgery His blood-pressure fell from 254/150 to 220/110–120 mm Hg, the fall producing temporary improvement and mental clearing An attempt at retrograde aortography failed

Operation—On March 17, 1954, under spinal anæsthesia, left nephrectomy was done, with resection of a segment of the left renal artery At operation a pulseless renal artery and an apparently normal kidney confirmed the preoperative diagnosis of a Goldblatt kidney

Pathology—The operation specimen consisted of a section of stenosed renal artery, its lumen being reduced by 85% (fig 1), and the left kidney (118 g), whose capsule stripped easily The cortex measured 4 mm and the pyramids 11 mm The mucosa of the renal pelvis was slightly hæmorrhagic Microscopically the nephrovascular units were well preserved (fig 2), arteries and arterioles being normal Mild fibrous infiltration and lymphocytes were found in both the parenchyma and the capsule A few tubules were dilated with either hyaline or protein casts Microscopic sections of the

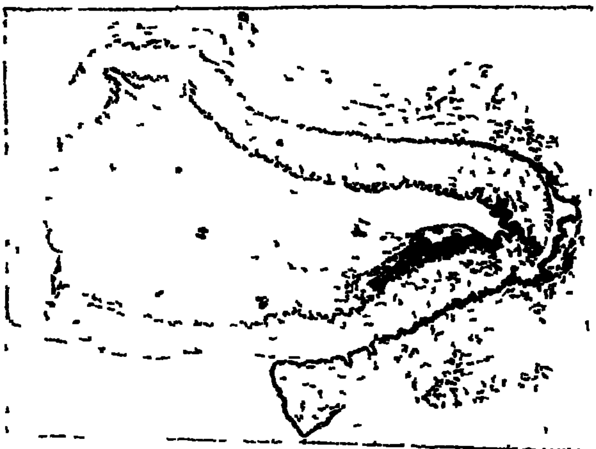

Fig 1—Cross-section of renal artery at site of maximal stenosis (Elastic-tissue stain)

renal artery showed extensive fibrous proliferation of the intima The elastic intima was distinct Occasional focal infiltration of lymphocytes in the proliferating intimal layer gave the picture of acute inflammation Unfortunately a biopsy specimen of the right kidney was not available to confirm feature no 3 of the syndrome (see above) We believe that this case satisfies the criteria outlined by Homer Smith (1948) for cure of hypertension by nephrectomy

Postoperative course—Striking changes followed surgery At the beginning of the operation the patient's blood-pressure was 250/150 mm Hg, and at its end 210/110 mm Hg By 10 P M that evening it was 154/90 mm Hg and by midnight 100/70 mm Hg When the electrocardiogram suggested myocardial ischæmia, noradrenaline was started by intravenous drip, and the blood-pressure rose to 180/100 mm Hg By March 24, five days after nephrectomy, the blood-pressure became steady at about 160/80 mm Hg There was never any evidence of surgical shock By March 27 there had been spectacular improvement in the visual acuity of the left eye, and the papillœdema in the right eye had disappeared The ophthalmologist considered the retinopathy to be grade IV on April 2, with corrected vision of 20/60 O D , 20/20 O S , and the capacity to read Jaeger-3 print A week later the corrected vision was 20/20 O U , and the patient could read Jaeger-1 Retinopathy was estimated at grade II on April 23 Lumbar puncture eleven days after the operation produced C S F under a pressure of 100 mm H_2O and containing protein 14 mg per 100 ml , compared with 340 mm H_2O and 150 mg per 100 ml preoperatively By April 21 the urine contained no albumin The blood-urea nitrogen was 26 mg per 100 ml four days before the operation, 17 mg per 100 ml by June, and 12 mg per 100 ml in December, 1954, and the urinary excretion of phenolsulphonphthalein had improved by August 24, 1954, to 40% in 15 minutes and 76% in 1 hour A bromsulphalein test on admission showed that 20% of the dye was retained, but on April 2, 1955, only 6% was retained The hæmoglobin increased to 14 6 g per 100 ml in August, 1954 On radiography the transverse diameter of the cardiac silhouette decreased to 143 mm by April 5, 1955, the radiological signs of pulmonary congestive completely disappeared, and electrocardiography showed less signs of left ventricular strain The preoperative electroencephalogram was interpreted as dysrhythmic, revealing many more frequencies of higher than average amplitude, especially in the frontal and central areas, these were described as consistent with disordered cerebral metabolism On Sept 14, 1955, electroencephalography showed remarkable improvement On admission the patient weighed 134 lb , and he claimed to have lost 40 lb in the preceding seven months By June, 1954, his weight had risen to 150 lb , and he said he had never felt better, being totally free from dyspnœa, palpitation, and headaches, and that his sight was constantly improving He was walking three or four miles daily During July, 1954, he drove his car 400 miles through Canada and then returned to his former job as a weaver in a textile mill, where he tends 52 looms

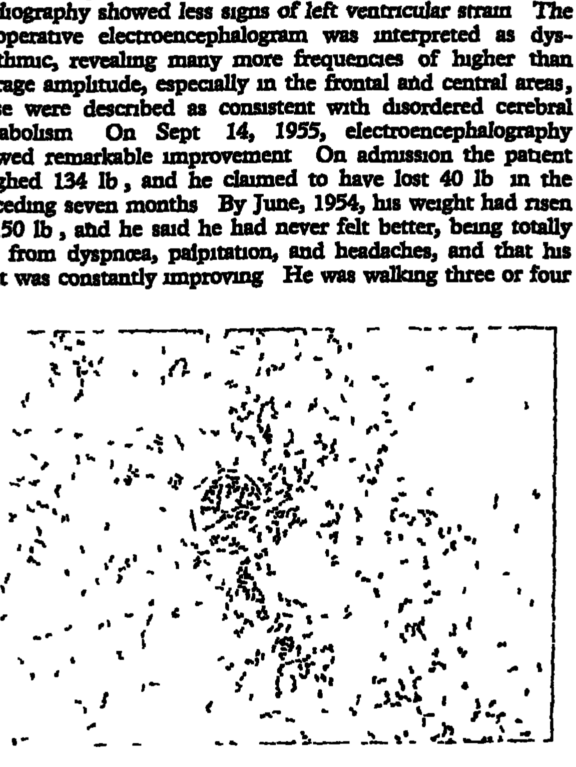

Fig 2—Random section from kidney, showing normal structure (Hæmatoxylin and eosin)

Follow-up—The patient was last studied in this hospital in December, 1957 (about four years after nephrectomy) For one and a half years after the operation he had remained in excellent general condition without medication of any kind and continued to maintain the striking improvement already described During the past year and a half, because his systolic blood-pressure had been found at times to be 180 mm Hg, his personal physician had treated him with hydrallazine rauwolfia ('Raudixin') At follow-up his blood-pressure was 166/80 mm Hg in the recumbent position and 140/70 mm Hg when he was standing Radiography of his chest showed the cardiac silhouette unchanged from two years ago, it remained slightly enlarged without signs of congestive failure An electrocardiogram was also identical with that of March, 1955 His urine contained no albumin, sugar, or pathological sediment His optic fundi were examined by the same ophthalmologist who had observed him before and after nephrectomy, no changes were found from their condition at September, 1955, and the patient's vision was O D 20/25, O S 20/30 (with glasses) The ophthalmologist's impression was grade-II hypertension, grade I/II arteriosclerosis The patient reported "feeling better than ever," sleeping soundly, and without headaches He walks daily about two miles without discomfort

Discussion

Experimental Background

In their original and subsequent investigations Wilson and Byrom used the Wistar strain of rats, which were prepared by applying an annealed silver ribbon clip to one of the main renal arteries after the method of Pickering and Prinzmetal (1938) In 65% of the rats so manipulated severe hypertension was produced in 1–28 days and lasted, in some rats, nine months The silver clip was applied so as to narrow the main renal artery without completely occluding its lumen, accomplishing the same thing technically and physiologically as the Goldblatt clamp Daniel et al (1954) have shown, by angiography, vasoconstriction of the intrarenal blood-vessels and parenchymal ischæmia within the "clipped" kidney in hypertensive rabbits Wilson and Byrom found in 77% of their rats malignant nephrosclerosis in the unclipped kidney and normal histology in the protected "clipped" kidney

Now Goldblatt, who failed to reproduce these findings in the dog and the sheep, considered that the characteristic malignant arteriolar lesions in the unclipped kidney of the rat could have been the result of pyelonephritis or of unrecognised disease in the clipped kidney Wilson (1953) then re-examined their material by using their control rats and concluded that their original interpretation of the renal lesions was correct and that the lesions were not the result of laboratory infections Confirmation of these unusual vascular findings by Daniel et al (1954) suggests strongly that the rat's kidney behaves more like the human kidney than like that of the dog Species differences are well known in laboratory investigations (Daniel et al 1952)

Wilson (1953) next made some experiments which even more closely incriminated the kidney in hypertension He noted that, if a rat was made hypertensive by the application of a clip to one main renal artery, excision of the contralateral unclipped kidney did not lower the blood-pressure, but, if the clip was removed to the main artery of the other kidney the blood-pressure usually dropped to normal

The foregoing experiments were made on rats with acute hypertension but subsequent experiments on rats with long-standing hypertension showed that, in chronic hypertension, simple removal of the clip often did not reverse the hypertension. Wilson (1953) considered that this was due to irreversible changes within the other kidney, which in time came to resemble the effect of a "clip" in producing renal ischæmia.

In further support of their theory they produced chronic hypertension by stenosis of one renal artery until the damage in the contralateral kidney was irreversible. The clip was then removed, and the hypertension persisted. Finally, the unclipped kidney with irreversible changes was removed from these rats with chronic persisting hypertension, and the blood-pressure promptly fell to normal. Such observations lend strong support to the renal genesis of this type of hypertension and of the malignant variety in particular.

Abeshouse (1941) reviewed the published cases and enumerated the underlying lesions, ranging from renal tuberculosis to renal aneurysms. However, at that time the significance of stenosis of the main renal artery as a cause of hypertension was not fully appreciated. In a complete review of the English and American published cases we have found 21 in which stenosis of the main renal artery of one kidney was considered to be the chief cause of the hypertension. All these cases have certain clinical and pathological features in common which imitate the experimental syndrome in rats. Although certain data are missing, one can justifiably presume what the completed picture would be and infer that these cases represent hypertension resulting from stenosis of a renal artery, with pathological changes reaching one of the several stages of the experimental syndrome.

In the 9 cases in which both kidneys were examined few if any pathological changes were reported in the kidney protected by the stenosis, whereas in the contralateral kidney were severe degenerative changes mainly resembling nephrosclerosis. This dissimilarity between the two kidneys is difficult to explain on a basis of chance findings. In the present case the renal histology was not remarkable in the excised kidney (which was protected by the stenosed artery in a manner comparable to the clipped kidney in the rat), but the changes in the arterioles of the ureter suggest that there may well have been vascular changes in the other kidney. In 14 of the 21 cases nephrectomy cured the hypertension. In 1 case the stenosis of the artery was alone corrected without removing the kidney, and normotension was restored. It is reasonable to suppose that some of the patients who died could have been saved by nephrectomy.

We must emphasise again that we have reviewed only those 21 cases in which a main renal artery to one kidney only was stenosed. In 1 case the stenosis was due to encroachment by a tumour, in 1 other it was caused by an aneurysm, and in the remaining 19 the artery was narrowed by an arteriosclerotic plaque (but histological proof was not always obtained). Although encephalopathy developed in 8 cases, 3 of these patients were still well at the end of two years, and in the remaining 5 cerebral changes were not mentioned, or else the disease had not progressed so far. Uræmia was an accompanying condition in only 3 of the 8 with encephalopathy. All 8 had severe hypertension, the lowest blood-pressure being 180/110 mm Hg. These observations show how closely human material, even in limited amount, fits the criteria which appear to be important in the experimental syndrome in rats.

In looking for published cases of stenosis of a main renal artery we found 20 other cases of hypertension thought to be the result of renal ischæmia but excluded them for various reasons (Bourne 1954, Masiloff and Macht 1951, Aronson and Sampson 1951, Perera and Haelig 1952, Fishberg 1941, Wainwright 1949, Hussar and Bernstein 1954, Prinzmetal et al. 1942, Howard et al. 1954, Blahd et al. 1952, Yuile 1944, Leiter 1938, Hoffman 1942, Perry 1945).

Diagnosis

Clinicians are cautious about diagnosing hypertension due to unilateral renal disease. The treatment implies nephrectomy, and past experience has shown that only a fifth of the unselected cases of hypertension and unilateral renal disease would be helped. However, if the syndrome accurately resembles that described here, the cure-rate will be very much higher.

The ideal candidate is a patient with severe hypertension (a raised diastolic blood-pressure of 110 mm Hg or higher) in whom the disease is rapidly progressing and more organs are becoming affected. The heart may exhibit severe electrocardiographic changes, left ventricular strain, and T-wave changes. Encephalopathy with coma, stupor, or convulsions may ensue. The signs may vary according to the duration and severity of the hypertension, but, if the changes are severe, there is all the more reason for considering the present syndrome, the severity of these changes should not contraindicate surgery. Intravenous and retrograde pyelography should aid in localising the disease, but their interpretation may be uncertain, as the 2 cases of Howard et al. (1954) showed. If there are electroencephalographic or other cerebral changes, lumbar puncture should be done to rule out arteriosclerotic encephalopathy. Pickering *et al.* (1952) observed that, when albuminuric retinitis is present, the pressure of the C.S.F. is nearly always above the level at which brain tumours cause papillœdema. In arteriosclerotic retinitis with encephalopathy the pressure of the C.S.F. is lower. The usual renal-function tests are not easy to assess, because apparently poor function can be reversed dramatically after nephrectomy. The regitine test is of no value, because it may be positive in the present syndrome and in the presence of uræmia, as is well known. If intravenous pyelography is not conclusive, aortography is of the greatest importance, as in the cases reported by Howard et al. (1954) and Freeman et al. (1954).

The ocular fundi should be carefully examined. The observation of Volhard and Fahr (1914) that the distinctive feature of malignant hypertension is albuminuric retinitis (hypertensive neuroretinopathy) still receives strong support. It is distinguished from arteriosclerotic retinitis by the presence of bilateral neuroretinal œdema, which is absent in arteriosclerotic retinitis except as a consequence of venous thrombosis.

Recent studies by Howard et al. (1956) indicate that there is a method of detecting the "endocrine" kidney when intravenous pyelography and/or aortography are negative: urine is collected from each kidney through retrograde catheters, and the amounts of sodium and chloride in it are measured. The endocrine or pathological kidney is detected by its decreased excretion of sodium and water.

Pathology

A study of 21 published cases selected as representing the syndrome produced experimentally in rats by Wilson and Byrom (1939) has brought forth very interesting facts. *In all* of them a renal artery was narrowed. Of the 11 surviving patients who underwent nephrectomy no histological data are available about the kidney which still remains in situ, but of the excised kidneys 7 had completely normal renal parenchyma, 3 had areas of tubular atrophy, and 1 had interstitial inflammation and fibrosis These latter abnormalities were not considered severe enough to cause the hypertension Of the 8 patients who died 7 at necropsy had malignant nephrosclerosis of the kidney whose artery was patent and only minor or indifferent changes in the kidney protected by the stenotic artery In Stewart's (1941) case there was parenchymal atrophy only on the side where the artery was fully patent, this case should therefore probably not be considered typical of the present syndrome, because it does not fulfil all the criteria Blackman (1939) found at necropsy narrowing of the renal artery in 43 of 50 cases of essential hypertension but only in 5 of 50 non-hypertensives Narrowing of the artery per se is therefore insufficient to diagnose the present syndrome, the diagnosis must rest on the complete clinicopathological picture The 2 cases reported by Thompson and Smithwick (1952) are exceptional in that, as a result of biopsy, definite dissimilarities between the affected and the "protected" intact kidneys of surviving patients were observed the pathological changes in the "protected" kidneys were minimal in contrast to those in the other kidneys with patent arteries This shows the value of renal biopsy as a guide to prognosis and diagnosis

Treatment

This syndrome has been alleviated surgically in various ways, but the series is too small for statistical analysis Of the 21 cases 11 were cured by nephrectomy In 1 case (Freeman et al 1954) relief of the stenosis of the renal artery lowered the blood-pressure In another case (Thompson and Smithwick 1952) removal of an aneurysm did not change the blood-pressure, but it is not stated whether the diameter of the artery had been changed, as was so well shown by aortography in the case of Freeman et al (1954) Goodman (1952) reported a case in which neither medical treatment nor bilateral lumbodorsal sympathectomy altered the course of the disease, which was fatal Thompson and Smithwick (1952) also noted failure of lumbodorsal sympathectomy to effect improvement

The importance of the cure-rate in relation to the pathology is shown by Smith (1948) in his review of 242 nephrectomies done on patients with hypertension and various renal diseases, his cure-rate being only 19% However, his criteria for cure were rather rigid, and we prefer a higher residual systolic level than 140/90 mm Hg provided there is evidence of reversal of the disease in other organs, as was shown in the present case In the 21 selected cases with renal-artery stenosis the cure-rate for such severe hypertension is remarkable and shows that satisfactory treatment and recovery are possible when the present syndrome is correctly diagnosed

The varied effects of acute and chronic hypertension in the rat suggest the following alternatives

(1) If the hypertension is of short duration, either nephrectomy or removal of the constricted part of the renal artery should relieve the hypertension

(2) If the hypertension has lasted long enough, removal of the "clipped" kidney may be insufficient to relieve the hypertension, because the changes in the other kidney have become irreversible, and lumbodorsal sympathectomy also may be necessary

The challenge to the surgeon lies in a better preoperative selection of the patients who will benefit solely by nephrectomy The test of Howard et al (1954) is most important in this connection

Summary

A clinicopathological syndrome of hypertension which is cured by nephrectomy is discussed

Wilson and Byrom had previously described this syndrome in rats

A human case is now reported

A review of the published cases suggests that this syndrome is less rare than is usually supposed

Addendum

Since the preparation of this manuscript Poutasse and Dustan (1956) have described some cases of this syndrome

NUCLEAR CHANGES IN ORAL EPITHELIAL CELLS IN SUBACUTE COMBINED DEGENERATION OF THE SPINAL CORD DUE TO VITAMIN-B_{12} DEFICIENCY

S T Boen

OF THE DEPARTMENT OF INTERNAL MEDICINE,
BURGERZIEKENHUIS, AMSTERDAM

To make the diagnosis of subacute combined degeneration of the spinal cord due to vitamin-B_{12} deficiency is seldom difficult when there is a concomitant megaloblastic anæmia with a histamine-refractory achlorhydria But when there are no changes in the blood and bone-marrow the clinical picture differs little from that of other diseases affecting the posterior and lateral columns Formerly the diagnosis could be reached only *ex juvantibus*, on improvement under treatment with liver extract or vitamin B_{12}, but in recent years more certainty has been obtained by demonstrating a low serum-vitamin-B_{12} level (Mollin and Ross 1954, Victor and Lear 1956, Killander 1958, Spray and Witts 1958) or an impaired

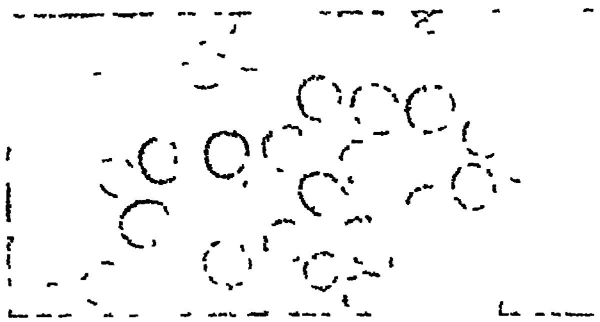

Fig 1—Blood-picture before treatment (×720.)

absorption test with radioactive vitamin B_{12} (Berlyne et al. 1957).

One of us described nuclear changes in oral epithelial cells in patients with pernicious anæmia (Boen 1957). In association with marked nuclear polymorphism, the presence of giant nuclei was characteristic. The nuclei were more or less round and had a finely reticulate chromatin structure. Their greatest diameter was on the average, above normal. Farrant (1958) found that both the longer and the shorter axes of the nuclei were higher in pernicious anæmia than in controls—especially the shorter. This last finding can, we think, be explained by so many of the nuclei being nearly round.

The question arose whether the nuclear changes would be found also in those rare cases in which vitamin-B_{12} deficiency is manifested by neurological disorders without hæmatological changes (Boen 1957). Recently we were able to study such a case.

Method of Investigation

The patient is asked to rinse his mouth thoroughly three times with physiological saline solution so as to remove food remnants. The mouth is then washed twice again, and the material thus obtained is centrifuged for about 10 minutes at 1000 r.p.m. The sediment is smeared evenly on microscope slides with a vaccinostyle, air-dried, and stained with May-Grünwald-Giemsa stain. A hundred consecutive nuclei are measured in their greatest diameter with an ocular micrometer using an oil-immersion objective.

Normally a maximum of 5% of the nuclei have diameters of 14·5 μ or more; in seven out of ten patients with pernicious anæmia the nuclei were definitely abnormal; in these seven cases we found the large nuclei in an average of 26%.

Case-report

Miss A, aged 57, had worked as a charwoman for the past six years without any long absences through illness. In July, 1957, she noticed tingling at the volar side of the fingers, but it did not interfere with her work. In October she complained of increasing general weakness, and had to take to her bed. She had uncontrolled jerks of the legs, paræsthesiæ, and numbness of the feet, and could barely walk from bed to table. In December she was admitted to the Burgerziekenhuis.

Examination showed no anæmia, icterus, or œdema; the liver and spleen were not enlarged. There was no glossitis, and the tongue was normally papillated except at the edges. Dr. S. Waterman, neurologist, found hypotonia and paresis in both legs (affecting the proximal part more than the distal), hyperactive patellar and Achilles reflexes, and slight ataxia. Somewhat later Dr. P. L. Braat, neurologist, also found impaired vibration sense in both legs and loss of position sense in the toes. There were bilateral extensor plantar responses, positive Chaddock and Mendel-Bechterew reflexes, and on the left side knee clonus. The cerebrospinal fluid was normal in pressure, clear, and colourless, and contained no granulocytes; the Wassermann, Pandy, and Nonne reactions were all negative.

Hæmoglobin 14 g. per 100 ml. Sedimentation-rate (Westergren) 7 mm. in one hour. Serum not icteric. Leucocytes 7800 per c.mm. (eosinophils 1%, granulocytes 69%, lymphocytes 24%, monocytes 6%). No hypersegmentation of granulocytes. Erythrocytes normal (except for slight anisocytosis); no megalocytes (fig. 1). Number of platelets normal. Bone-marrow picture entirely normal; no megaloblasts or giant metamyelocytes. Reticulocyte-count 1·5%. Serum-iron concentration 140 γ per 100 ml. (normal).

Fig 2—Mouth-washing before treatment. Giant nucleus beside normal ones. (×900.)

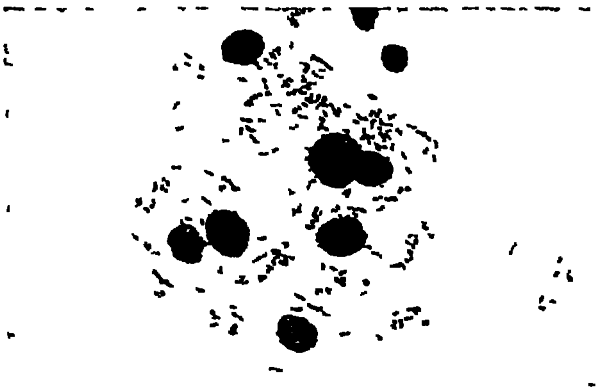

Fig 3—Mouth-washing before treatment. Polymorphism of nuclei. Typical of vitamin-B_{12} deficiency. (×400.)

Gastric analysis showed histamine-refractory achlorhydria. The luetic serological reactions were negative. The urine, with a specific gravity of 1·029, contained no urobilin.

In contrast to the hæmopoietic system the oral epithelial cells were distinctly abnormal. There was pronounced polymorphism of the nuclei and there were characteristic giant nuclei, more or less round and with a finely reticulate chromatin structure (fig. 2). 19% of the nuclei had a diameter of at least 14·5 μ, compared with 5% or less in normal people (fig. 3).

A diagnosis of vitamin-B_{12} deficiency was made on these changes in the epithelial cells of the mouth, and the patient was treated with 100 γ vitamin B_{12} by intramuscular injection daily for 3 weeks, and thereafter once a week. Her legs gradually grew stronger and after a month she could walk short distances without support. The paræsthesiæ, the numbness, and the abnormal reflexes disappeared. The slight ataxia and the impairment of vibration sense remained.

The administration of vitamin B_{12} had no influence on the reticulocyte-counts, the hæmoglobin concentration, or the serum-iron level. These prove that the hæmopoietic system had not suffered from the deficiency.

The oral epithelial cells were normal again a week after the beginning of treatment. Fig. 4 shows the distribution of the nuclei on different days: by the 5th day large nuclei had disappeared. This reaction to vitamin B_{12} is similar to that of patients with classical pernicious anæmia (Boen 1957). In fig. 5 the more monomorphic picture of the nuclei can be seen.

Another proof of the correctness of the diagnosis was the low serum-vitamin-B_{12} level before treatment—namely, 60 μμg

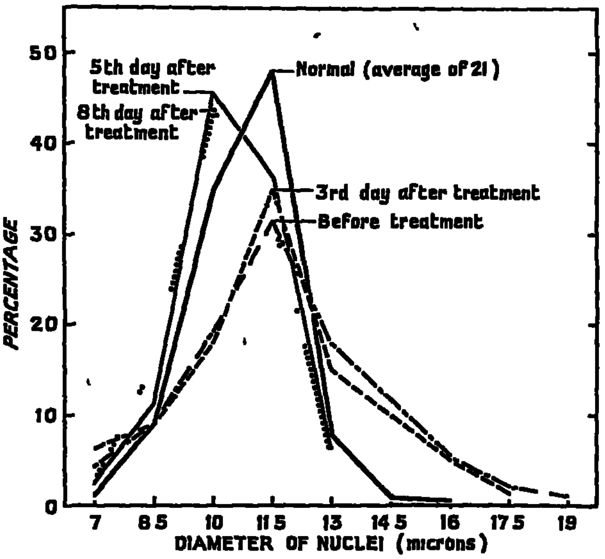

Fig 4—Distribution of nuclei on different days after beginning treatment with vitamin B_{12}

per ml (normal 150–500 μμg) * The outcome was known to us only later, when the patient was recovering

Discussion

It is generally agreed that patients with subacute combined degeneration of the spinal cord concomitant with pernicious anæmia have a low serum-vitamin-B_{12} level, whereas in those with other neurological disorders it is normal (Mollin and Ross 1954, Victor and Lear 1956, Killander 1958, Spray and Witts 1958) The absorption test with radioactive vitamin B_{12} has also been used for the differential diagnosis of neurological diseases (Berlyne et al 1957) This test is not always useful, because impaired absorption is not necessarily associated with deficiency, since there may be a large stock of vitamin B_{12} in the body Again, though absorption is normal, there may be deficiency because the diet, over a long period, contains too little vitamin B_{12}, as in some vegetarians (Badenoch 1956, Booth and Mollin 1957) The characteristic changes in the nuclei of the oral epithelium, however, appear to be definite evidence of vitamin-B_{12} deficiency Their detection is easy and the method is suitable for clinical purposes

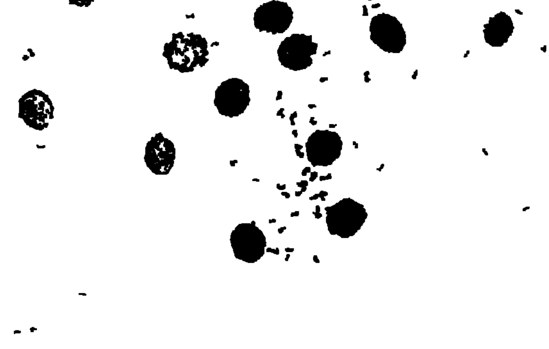

Fig 5—Mouth-washing on 8th day of treatment Normal picture (×400)

A normal nuclear pattern does not exclude a vitamin-B_{12} deficiency In three out of ten patients with perniciou anæmia the nuclei were normal (Boen 1957) Farran (1958) also found a normal average diameter in some o his patients

Summary

A woman, aged 57, had had subacute combine degeneration of the spinal cord for several months, bu showed no changes in the blood or bone-marrow Th diagnosis of vitamin-B_{12} deficiency was made on charac teristic nuclear changes in the oral epithelium On treat ment with vitamin B_{12} she much improved and th nuclei of the oral epithelium became normal within week of the start of treatment No changes were seen i the hæmoglobin concentration, reticulocyte-counts, o serum-iron level The diagnosis was confirmed b demonstration of a low serum-vitamin-B_{12} level befor treatment (60 μμg per ml)

We are grateful to Prof J G G Borst for his encouragement, to Mrs J M den Ottolander-Claremont for correcting our English and to Organon-Oss for estimating the serum-vitamin-B_{12} level

---

* The assay was done in the microbiological department of Organon-Oss, using *Lactobacillus leichmannii*

SARCOIDOSIS OF LIVER AND SPLEEN

John C Roberts
M D Lond, M R C P
PHYSICIAN, HAREFIELD HOSPITAL, MIDDLESEX

Mercer C Rang
M B Lond
FORMERLY CASUALTY OFFICER, MOUNT VERNON HOSPITAL, NORTHWOOD, MIDDLESEX

Sarcoidosis is now being diagnosed more often than formerly Its ætiology is still a subject of controversy Whereas many physicians regard sarcoidosis as an unusual response to tuberculous infection, others regard it as a reaction to various exciting causes

Sarcoidosis may affect the skin lymph-nodes, the eyes, the salivary glands, the lungs, the bones of the hands and feet, the liver, and the spleen The Mantoux reaction is often negative but may be positive, and then usually only weakly so The lesions are granulomatous and resemble tubercles, but caseation is absent, and tubercle bacilli are never found

The case reported here is unusual for three reasons the sarcoid lesions were demonstrable only in the liver and spleen, the patient was aged only 13, and the spleen ruptured, enabling us to follow the effect of splenectomy on the disease

Case-report

A boy, aged 13, attended Harefield Hospital on July 29, 1956, with two months' history of being off colour, with periodic attacks of epigastric pain and vomiting associated with rigors and anorexia He had possibly been jaundiced a month before Recently he had had pain in the left lower part of his chest, with a feeling of tightness on breathing and coughing There was nothing relevant in his past or his family history

Nine siblings had been free from similar illness

On admission to hospital on July 29, 1956, the patient looked pale and ill but was not jaundiced His temperature was 99°F and pulse-rate 76 The only abnormal physical signs were some impairment of percussion note, weak breath sounds at the left base, and a liver that was just palpable

Investigations—Radiography of his chest showed opacity at the left base but no abnormal hilar shadows Bronchography showed a normal bronchial tree The Mantoux reaction was positive at 1/100, but the reaction was not brisk Acid-fast bacilli were not seen or cultured in thirteen specimens of sputum The urine contained no bile or urobilinogen The erythrocyte-sedimentation rate (E S R.) was 20 mm at the end of one hour (Westergren), and the white blood-cells numbered 7500 per c mm

Progress—For two weeks the patient's evening temperature was 99°F (see figure) The E S R was 8 mm at the end of one hour at the end of this time 'Distaquain' penicillin 300,000 units was then given for eight days, during which time his evening temperature fell to 98 4°F, but it rose to 99 8°F when the penicillin was withheld and fell to 98·4°F when the penicillin was resumed Then the boy was allowed home for a weekend On his return he said that on the previous evening he had had abdominal pain and a headache and had vomited He felt better on return but looked ill and tired, and his temperature had risen to 100°F Jaundice was absent, and no lymph-nodes were palpable. His spleen had become palpable and his liver larger The Paul-Bunnell reaction was negative, a blood-culture was sterile, the Wassermann reaction and the Kahn test were negative, and acid-fast bacilli were not found either on direct examination or on culture on numerous occasions throughout his illness Reticulocytes were less than 1%, and sternal marrow showed a maturation defect of red and white series Liver-function tests showed alkaline phosphatase 8 King-Armstrong units, bilirubin 0 2 mg per 100 ml, thymol turbidity 1 unit, no flocculation, total protein 7 12 g per 100 ml (albumin 5 25 g per 100 ml., and globulin 1 87 g per 100 ml) The liver and spleen continued to increase in size, and the temperature swung between 100° and 104°F Penicillin appeared to lower the temperature to 99°F in the evenings There was still no other abnormality, so on Sept. 14, 1956, the abdomen was opened

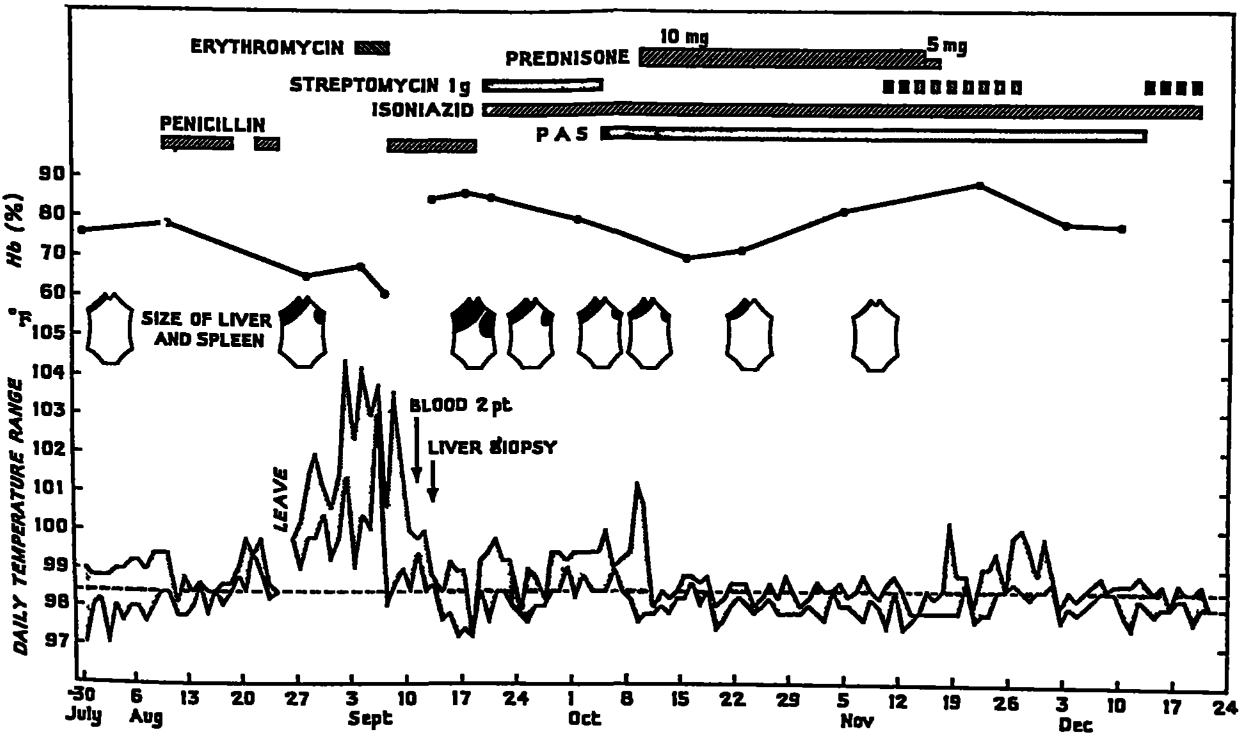
On laparotomy the liver was found to be enlarged and looked normal but was rather firm The spleen was smooth and much enlarged No other abnormality was found in the abdomen A biopsy specimen taken from the liver showed scattered aggregations of epithelioid cells, some with giant cells, there was no caseation, and tubercle bacilli were not seen Sarcoidosis was diagnosed

Postoperative course—This was uneventful, and treatment with isoniazid and streptomycin was started Because of hypersensitivity p- aminosalicylic acid was later substituted for the streptomycin The liver became a little smaller, but the boy was still pyrexial and miserable Treatment with prednisone produced a dramatic response the boy looked better, his pyrexia fell by crisis, and in forty-eight hours his liver was much smaller and his spleen impalpable His liver continued to decrease, and the drugs were stopped He had slight pyrexia for a fortnight after the prednisone had been stopped, but thereafter his temperature was normal

On discharge in March, 1957, he was apyrexial and had put on weight, and neither liver nor spleen were palpable The E S R was 20 mm at the end of one hour (Westergren) During all this time he had remained anæmic At the onset his hæmoglobin was 68%, white-cells 3500 per c mm, and platelets 100,000 per c.mm This condition was unaffected by chemotherapy and parenteral iron Prednisone, however, caused the hæmoglobin to increase by 20%

Readmission—In August, 1957, because of pyrexia and occasional nausea and vomiting the patient was reinvestigated During ten days in hospital he had no pyrexia and no abnormal physical signs Liver-function tests were normal, agglutination reactions against salmonella and brucella were negative, the hæmoglobin was 80%, and the E S R was 20 mm at the end of one hour (Westergren)

Rupture of spleen—On Sept 6, 1957, the boy was thrown off his bicycle, striking his left side on the handlebars He was admitted to Mount Vernon Hospital half an hour later He complained of severe upper abdominal pain, mainly on the left side



Treatment and progress

On examination he was vomiting and presented the signs of acute hæmorrhage, his abdomen was tender all over but maximally in the left hypochondrium, where guarding was present His abdomen was slightly distended, and shifting dullness was present on the right side Shoulder pain was absent

At laparotomy by Mr Alan Shorter two hours later, his abdomen was found to contain a pint and a half of blood, and there was a tear at the hilum of the enlarged spleen Splenectomy was done and three pints of blood transfused Convalescence was uneventful, and the boy was discharged on the eleventh postoperative day with hæmoglobin 74%

Operation specimen —The excised spleen weighed 370 g (normal for age, 100 g) and had a transverse tear extending from the hilum for 5 cm Its capsule was smooth and covered with blood-clot On section a central band of hæmorrhage at the site of the tear was seen, flanked by pale splenic substance showing fine white mottling Microscopy showed an area of interstitial hæmorrhage surrounding the tear and the typical appearances of active sarcoidosis in the splenic substance (small aggregations of epithelioid cells, some with giant cells, surrounded by a thin zone of lymphocytes, but no caseation)

Follow-up —Seen on Dec 13, 1957, three months after the operation, the boy was in excellent clinical condition His liver was impalpable, his hæmoglobin 92%, E S R 8 mm at the end of one hour (Westergren), white cells 12,100 per c mm (polymorphs 45%, lymphocytes 46%, eosinophils 6%, basophils 2%, monocytes 1%)

Comments

In this case the presenting symptoms of pyrexia and malaise were probably due to the sarcoid lesion The cough and tight feeling in the left side of the chest may have been due to the slight changes in the left base but were more probably due to irritation of the diaphragm by an enlarging spleen

Antituberculous drugs were without much effect, but prednisone appeared to suppress the disease That it was only suppression was realised ten months later, when section of the spleen showed active sarcoid The figure shows the increase of hæmoglobin associated with prednisone therapy and the relapse following its withdrawal The recurrence of anæmia suggests that the course of prednisone was inadequate Since the depressed hæmopoiesis caused few symptoms, surgery was not considered, but it became compulsory later by rupture of the spleen and then produced an increase of hæmoglobin, a rise in the white-cell count, and much improvement in the patient's general condition

We have watched this case for eighteen months and have at no time found any evidence of sarcoid lesions elsewhere The initial lesion in the chest did not resemble pulmonary sarcoid This is very unusual, and we have only been able to find one definite case with similar features published (Kay 1950)

Discussion

Sarcoidosis may be generalised or may appear in well-recognised groups of tissue

Mather et al (1955) have shown that, in all types of sarcoidosis, liver biopsy is positive in 63% of patients and the spleen is palpable in 14% Necropsy results put the incidence of splenic involvement at 50% (Branson and Park 1954), this is likely to be due to the impossibility of detecting slight enlargement of the spleen clinically and to the infrequency of splenic biopsy In this country involvement of the liver and spleen is generally silent and the patient is only conscious of the disease elsewhere In America cases of gross involvement of the liver and spleen, with symptoms of liver failure, have been described, but most of these are associated with manifestations elsewhere

Liver in Sarcoidosis

Although the liver is so often involved and enlarged in sarcoidosis, evidence of disordered function is uncommon in this country In the series of Mather et al. (1955) only 10% of the cases showed a raised serum-globulin level, and the finding bore no relationship to the presence or the absence of sarcoid lesions in the liver In the present case liver function was normal throughout

Jaundice is rare, Branson and Park (1954) found only 3 certain cases in 867 cases of sarcoidosis

Liver failure can occur in sarcoidosis, Branson and Park (1954) describe a fatal case in which jaundice, ascites, and hæmorrhage occurred

Kelley and McHardy (1955) report a man, aged 48, who developed obstructive jaundice due to hepatic sarcoid lesions The liver became fibrotic, and he died in liver failure He was treated with corticotrophin and deep X rays, the latter may have been a major factor in producing the cirrhosis

In these cases hepatic involvement was only part of a generalised sarcoidosis

Spleen in Sarcoidosis

Involvement of the spleen in the present case produced hypersplenic anæmia and was a contributory factor in rupture of the spleen

Hæmopoietic dysfunction is not uncommon in sarcoidosis Hypersplenism may depress the red cells, white cells, or platelets, either severally or together In the present case the red-cell count was chiefly affected, and the white-cell count during hyperpyrexia fell to 3500 per c mm , and for three months (from September to November, 1956) the platelet-count was 100,000–150,000 per c mm There were no purpuric manifestations Bruschi and Howe (1950) described a case in which splenectomy had to be done to relieve purpura

It is thought that the anæmia is due to exaggeration of the normal inhibition of the bone-marrow by the spleen Whether prednisone increased the hæmoglobin by acting directly on the marrow or by decreasing the volume of the spleen and the sarcoid lesions contained therein is questionable Shulman et al (1952) noted, in a series of cases, that corticotrophin caused rapid regression of hepato-splenomegaly, with occasional improvement of anæmia, but in most cases relapse followed the withdrawal of corticotrophin The similar effect produced by splenectomy has been recorded by Longcope and Freiman (1952) and Kay (1950)

Nausea, vomiting, and pain in the chest were all probably related to splenomegaly Splenectomy was done by Partenheimer and Meredith (1950) to relieve these symptoms

Spontaneous rupture of the spleen from sarcoidosis was the presenting symptom in a case described by James and Wilson (1946) and another by Phillips and Luchette (1952) The former patient was a man, aged 49, who had pulmonary lymphadenopathy and a normal-sized spleen, the diagnosis was made on finding sarcoid lesions in the spleen The latter patient was a man, aged 21, who had lymphadenopathy and a spleen weighing 306 g Neither of these patients had isolated sarcoidosis of liver or of spleen In the present case the rupture was traumatic, but probably the trauma would not have ruptured a normal spleen This accident enabled us to observe the persistence of the sarcoid lesions despite antituberculous chemotherapy and a short course of prednisone It also suggests that splenectomy would have controlled the anæmia had it been done before the rupture

Summary

A case of sarcoidosis of the liver and spleen is described in a boy, aged 13, complicated by hypersplenism and traumatic rupture of the spleen

We wish to thank Dr E Idris Jones, consultant physician, who originally referred the patient, Mr David Levi, consultant surgeon, for the liver biopsy, Dr E Nassau, pathologist and his staff for the histology of the liver biopsy, and Dr G S W Andrews and Dr J M Bennett, pathologists, of Mount Vernon Hospital, for the report on the spleen, and Mr A Shorter, consultant surgeon, for the splenectomy

DISSEMINATION OF MICRO-ORGANISMS BY A SURGICAL PUMP

IAN RANGER
M B Lond, F R C S
SURGICAL ASSISTANT

FRANCIS O'GRADY
M D, M Sc Lond
ASSISTANT PATHOLOGIST

THE MIDDLESEX HOSPITAL, LONDON, W 1

IN a case of staphylococcal subphrenic abscess treated by suction drainage by an electric pump it was noted that the outlet from the pump discharged directly into the ward When the air from the outlet of the pump was led to a slit sampler, it was found that large numbers of organisms were being ejected by this route

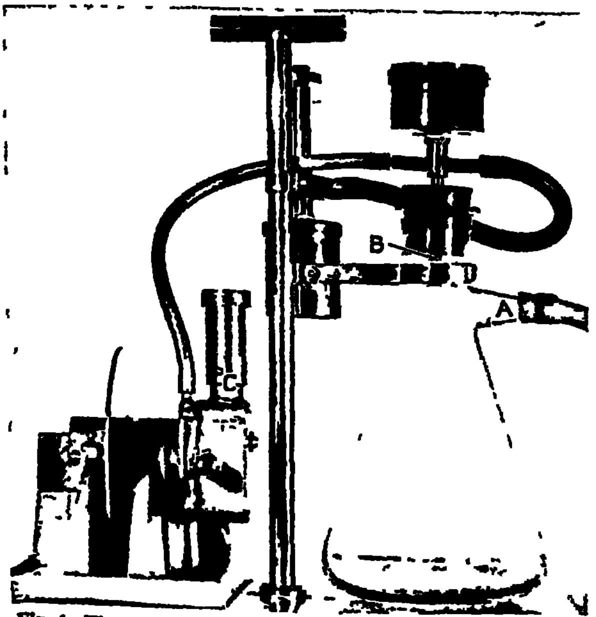

Fig 1—The pump assembly A, input to trap, B, outlet from trap to pump; C, outlet from pump (as modified)

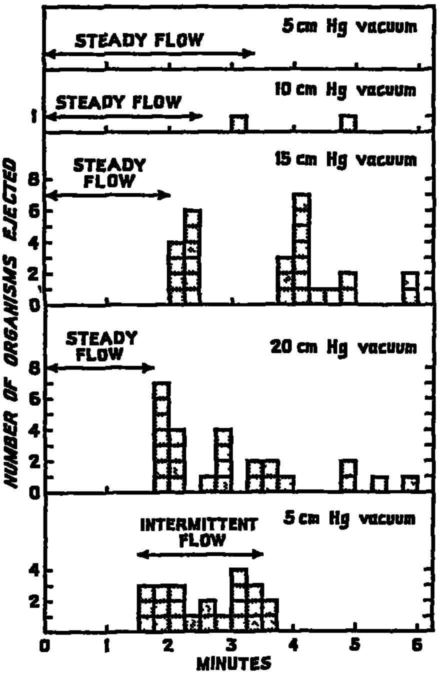

Fig 2—Numbers of organisms ejected from pump outlet at different pressures and flows

Since the discharge of organisms in this way into a surgical ward was clearly undesirable, experiments were instituted to show the degree of contamination of the atmosphere in this way and to find a way to prevent it

Degree of Contamination

The input to the trap (fig 1, A) was immersed in 200 ml of broth culture containing 100,000,000 organisms per ml, and the outlet from the pump (fig 1, C) was led by a sterile plastic tube to a slit sampler The pump was run at negative pressures of 5, 10, 15 and 20 cm Hg

Fig 2 shows representative examples of the results obtained With a vacuum of 5 cm Hg no organisms were ejected With the greater negative pressures used no organisms were ejected during the flow of the liquid, but a shower of organisms was ejected when the container emptied and air and froth were drawn rapidly into the trap (fig 2) The number of organisms ejected increased with increase of the vacuum, and this was partly because bubbles in the trap came into direct contact with the tube (fig 1, B) leading to the pump

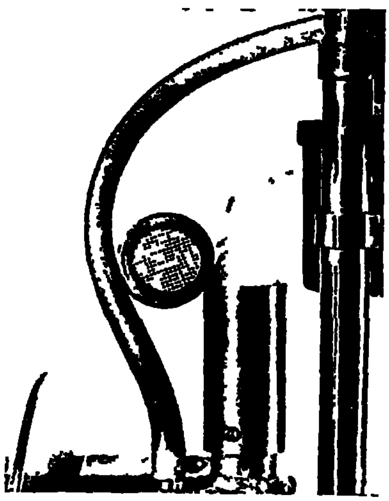

Fig 3—Filter assembly showing brass cylinder, mesh cap, and cotton-wool

In view of the importance of splashing and the likelihood of this occurring in practice when the drained cavity empties, experiments were conducted in which the

200 ml of culture was delivered at intervals by a siphon in 20-ml amounts In this way repeated splashing and frothing occurred In these circumstances 5–10 times as many organisms were ejected as when the same volume was delivered by direct flow (fig 2)

Prevention

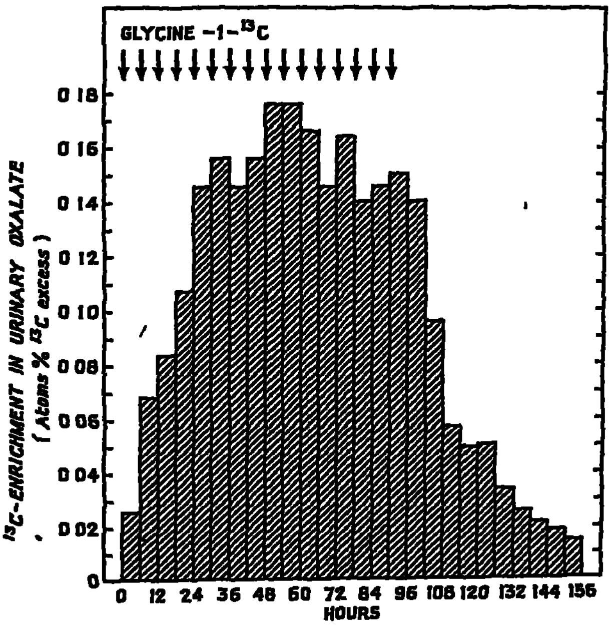
Ejection of organisms from this system was completely abolished by fitting to the output of the pump a brass sleeve, with a mesh floor and cap, lightly packed with non-absorbent cotton-wool (fig 3) This filter has remained effective during 24-hour periods of continuous running of a modified experimental system in which 20 ml amounts of culture were delivered at intervals of 2 minutes In practice the non-absorbent cotton-wool has been replaced every 24 hours when the pump was in continuous use

The brass sleeve was made by Mr D Brown, of the electrical engineer's department, Middlesex Hospital, and costs about 7*s* 6*d*

Preliminary Communications

INCORPORATION OF CARBOXYL-CARBON ATOM OF GLYCINE INTO OXALATE IN A CASE OF PRIMARY HYPEROXALURIA

PRIMARY hyperoxaluria [1] is characterised biochemically by a continuous urinary oxalate excretion equivalent to about 100–200 mg $(COOH)_2$ $2H_2O$ per 24 hours (The corresponding figure for normal people is less than about 40 mg) Clinically, these patients present in childhood with recurrent multiple calcium-oxalate urinary calculi and nephrocalcinosis, they die prematurely from renal failure, and at necropsy calcium oxalate crystals are demonstrable in some of the extrarenal tissues [2] Previous studies in this laboratory suggested that glycine is the precursor of at least some of the oxalate which they excrete [3]



The ^{13}C abundance in the calcium oxalate isolated from successive 6-hour urine collections in a case of primary hyperoxaluria given glycine-1-^{13}C orally at the times indicated by arrows

We recently administered glycine-1-^{13}C orally (2 56 mg per kg body-weight, 49 8 atoms % ^{13}C excess, 6-hourly for 4 days) to a patient with primary hyperoxaluria, the oxalate was isolated from successive 6-hour urine collections and its ^{13}C content measured There was prompt and considerable incorporation of the isotope into the urinary oxalate (see figure) This relation between glycine and oxalate in primary hyperoxaluria accords with our previous observation that in this disease large doses of sodium benzoate (given to deplete the free-glycine metabolic pool) decrease the urinary excretion of oxalate [3]

It has been shown that enzyme systems capable of degrading glycine via glyoxylate to formate and carbon dioxide are present in some mammalian tissues [4], also (during in-vitro experiments with rat liver) that, if the degradation of glyoxylate to formate and carbon dioxide becomes the rate-limiting step in the reaction sequence, oxalate is synthesised [5] Although our present findings are compatible with the view that the metabolic lesion of primary hyperoxaluria is in this path of glycine metabolism, they do not show whether the primary abnormality is (a) a failure to degrade glyoxylate to formate and carbon dioxide, or (b) an excessive—possibly abnormal—conversion of glycine to glyoxylate, the further metabolism of which is inherently limited

Other cases of primary hyperoxaluria are being studied, and we are comparing the isotope enrichment in the free urinary glycine (which we regard as a valid sample of the free-glycine metabolic pool [6]) with the isotope enrichment in the urinary oxalate The results of these investigations will be reported in detail elsewhere

We are indebted to Prof A Wormall, F R S , for facilities for the mass spectrometric analyses, and to our assistants Miss E D Bell and Mr L Rawlings for their help

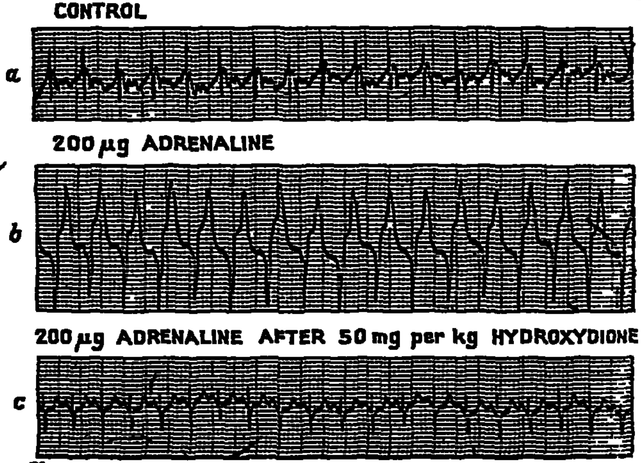
INHIBITION BY HYDROXYDIONE OF ADRENALINE-INDUCED ARRHYTHMIAS

DURING animal experiments, one of us (N R W T) noted that hydroxydione (21-hydroxypregnane-3, 20-dione sodium succinate) appeared to arrest cardiac arrhythmias in the isolated rabbit heart and to prevent their occurrence in cats A preliminary series of experiments has now been done to see if this drug would prevent arrhythmias induced with adrenaline

Five healthy cats were used, varying in weight from 2 to 3 5 kg They were lightly anæsthetised with ether, a tracheal cannula was inserted, and the blood-pressure was recorded from the carotid artery with a mercury manometer The drugs were given intravenously into the femoral vein The vagi were left intact, and continuous electrocardiograms were recorded using lead aVF as a control Gradually increasing doses of adrenaline, within the range 100–500 µg , were given intravenously and a



Showing the production of ventricular tachycardia in (*b*) and its prevention by hydroxydione in (*c*)

great variety of arrhythmias were induced—ectopic beats from multiple foci, coupled rhythm, nodal rhythm, and paroxysmal tachycardias The dose, which varied greatly from cat to cat, was stepped up in each case until paroxysmal ventricular tachycardia could be consistently produced 50 mg of hydroxydione per kg body-weight was then given intravenously, and after 6 minutes the previously determined dose of adrenaline was repeated In four out of five cats none of the previously recorded arrhythmias occurred (see figure), and after 50 to 100 mg hydroxydione per kg body-weight the dose of adrenaline had to be increased by 50–300% before the tachycardia was reproduced

It may be that hydroxydione or one of its congeners could prevent arrhythmias induced in other ways, and might be useful as an anæsthetic agent during cardiac surgery These possibilities are under study

We are indebted to Messrs Organon Laboratories for a supply of hydroxydione

Reviews of Books

Clinical Electrocardiography

The Spatial Vector Approach ROBERT P GRANT, M D, National Heart Institute, National Institutes of Health, Bethesda, Maryland London and New York McGraw-Hill 1958 Pp [illegible] 58s 6d

THIS outstanding book on clinical electrocardiography is based on a study of the direction of spread of the electrical forces of the heart as shown by the spatial vector It is Dr Grant's opinion that no loops need be actually calculated and no special apparatus is required He emphasises that the direction of the loop can be appreciated with sufficient accuracy by simply studying the standard limb and chest leads of the electrocardiogram.

The electrocardiogram is a graphic record of the electrical impulses which spread from the sino-atrial node across the atria to the atrioventricular node and then via the bundle of His to the ventricles These electrical forces are transmitted to the surface of the body and may be tapped at different points by leads attached to the limbs or chest wall—the electrocardiogram The form of the electrocardiogram in any one lead was once thought to reflect action potentials underlying the electrode, but it is now appreciated that it is merely tapping at one point the circuit of electrical forces which is described as the spatial vector or loop Thus, the electrocardiogram represents the total electric forces at the point on the limbs or chest wall from which the lead is taken, and is as much influenced by abnormalities of ventricular muscle on the opposite side of the heart as it is by abnormalities beneath the electrode The negative wave or Q wave of anterior chest leads in anterior cardiac infarctions, therefore, merely represents a retreat of the electrical forces posteriorly, away from the damaged area, and is accompanied by an increase in height of the R wave in posterior leads Conversely, in posterior cardiac infarction an increase in height of the R in anterior chest leads is just as important as the presence of a Q wave posteriorly

This is the vectorial approach and Dr Grant uses it to explain the whole of electrocardiography If this concept can be understood the laborious memorisation of electrocardiographic patterns becomes unnecessary Dr Grant's book should be read and re-read by every cardiologist or anyone training in cardiology The reader is not presented with a series of loops divorced from electrocardiograms, but is shown how to deduce the pattern of this loop from the routine electrocardiogram Knowledge of the approximate pattern of the loops greatly helps in basic interpretation, but the finer points for diagnosis are still obtained from changes in the form of the QRST complex picked up in individual leads The vector approach however, gives a broad view of the whole picture and is valuable for *understanding* abnormalities shown in the electrocardiogram

Although this is a book of first principles it is not a suitable book for the beginner, or for the occasional electrocardiographer, who will have to await a simpler volume, but preferably one based on the same principles

Law and Ethics for Doctors

STEPHEN J HADFIELD, M.B, D OBST, assistant secretary, British Medical Association London Eyre & Spottiswoode 1958 Pp 388 42s

IN the hundred years since the first Medical Act of 1858, few of the changes in the practice of medicine have made its conduct simpler, for increasing specialisation, the influence of the State, and the criticism of a more educated public have brought appreciable complications During the century, however, the profession has tested the principles of conduct which were its inheritance, and proved their fundamental strength These have remained constant while practice has altered, keeping in step with the community's needs

In this book Dr Hadfield has described the many points at which medicine makes contact with the community With so much ground to cover, some lack of detail or significant omissions might be pardoned, in fact, the book is outstandingly comprehensive, and even where complicated legal principles are being explained, the information is clearly presented Whether describing the ethical position of a doctor who broadcasts, the legal procedure of the Coroner's Court, or prescribing in the National Health Service, Dr Hadfield is readable and interesting

It is possible to practise for years, maybe a lifetime, without direct knowledge of the workings of courts of law, and of the many committees and tribunals which now exist under the National Health Service Many doctors have a vague impression of their existence and function somewhere in the professional background This book will give them a clearer picture To some extent it is also a catalogue of present-day medical thought and custom, and as such it is a historical document Moreover it is a source-book for the teacher of the undergraduate and the new entrant to practice, and a work of reference for the established practitioner

Does the place of the doctor in relation to the community, as here described, receive sufficient attention in the formal teaching of the medical student? There is much to be said for encouraging the student to make himself more fully aware of his future responsibilities towards his patients, his profession—and himself

Modern Trends in Endocrinology

Editor H Gardiner-Hill, M D, F R C P, consulting physician, St Thomas's Hospital, London London Butterworth 1958 pp 311 65*s*

This important Modern Trends series enables the clinician or the investigator to keep an eye on the growing points of knowledge that fall outside his own immediate interests Some sixteen subjects have now been covered, some of them by two or even three volumes, and this one is a notable addition It comprises 21 articles, about half of them devoted to the thyroid or the adrenal cortex The range is wide, and includes hormones of the adrenal medulla, serotonin, and gynæcological endocrinology The authors include physiologists, clinical investigators, and clinicians, and there is a pleasing variety about the style and approach of the different essays

Everyone, whether primarily an investigator or a clinician, will find something to his taste, and the postgraduate student will probably want to read the whole book But some readers will regret that in a book designed not only to satisfy curiosity but also to awaken interest the bibliographies do not include the titles of articles cited It is admittedly hard to persuade some authors to provide them, but the practice encourages the novice to explore his medical library, and saves the investigator some unnecessary excursions into it

Bridging the Gap

Editor R F Tredgold, M D, D P M, physician-in-charge, department of psychological medicine, University College Hospital, London London Christopher Johnson 1958 Pp 270 30*s*

Morbid public fascination by mental illness is well enough known and its dynamic origins are easy to understand not for nothing are new psychiatric works obligatory reading for Hollywood producers All too often what is written for the public is sensational, with grotesque distortions or malicious half-truths, and a book, therefore, which turns its back on Ruthless Exposures, and seeks rather to conciliate and explain, is to be welcomed Here a group of experts have written for the inquiring layman upon some aspects of the mental health services, and their sober reflections are placed alongside bitter and trenchant criticisms from ex-patients and others Emphasis is rightly placed on the harm done by mutual slanging matches between extremes of either side, and the need to travel the much harder road of reconstruction and improvement But this book is no act of whitewash Dr Donald Johnson, M P, hits out in one chapter with his customary vigour, and Dr J A R Bickford makes a splendid contribution on the psychiatrist's shortcomings and opportunities (his views should be obligatory reading for those in mental-hospital practice) Dr J A Scott has several chapters on the part played by the local authority, and, among others, Dr Desmond O'Neill writes on domiciliaries, Dr E W Dunkley on the observation ward, and Dr David Stafford-Clark on the psychopath There is an excellent brief account of the mental defective and a useful appendix summarising the laws related to mental hospital admission

It is perhaps inevitable that sensible balanced views should be slightly dull, but even allowing for this the book may disappoint some readers, perhaps because of the lack of continuity and repetitiveness But we hope it will reach the very wide public which it undoubtedly deserves

Marriage Counselling

J H Wallis, training officer, National Marriage Guidance Council, H S Booker, senior lecturer in statistics, London University London Routledge & Kegan Paul 1958 Pp 313 25*s*

This is an account by Mr Wallis of the origin, development, principles, and aims of the Marriage Guidance Council, the kind of problems brought by spouses in trouble, the methods of choosing and training counsellors (in detail) and (in less detail) the way they set about their work, followed by a statistical analysis by Mr Booker of some 25,000 "cases" recorded by counsellors in the years 1952–54, directed mainly to ætiology

Probably all family doctors over 40 and many other kinds of medical men or women have found themselves either essaying or resolutely declining the task of "marriage counselling" Of those not declining, probably only the few with psychiatric leanings and training—perhaps not even all these—will approach it without reluctance and misgiving It is surprising, then, that there is apparently no lack of volunteers ready to face a residential selection conference, based on the procedure of the War Office Selection Board, for the privilege of listening to and trying to help marriage partners in distress as "counsellors", part-time and unpaid No very clear picture emerges of the typical counsellor—if such a thing exists—either before or after training, and we do not know, for instance, whether a troubled spouse may expect to meet a counsellor of similar or dissimilar social or cultural class The chapters on the nature of counselling and people in difficulties are modestly and pleasantly written, but their matter is sadly familiar to the medical man and the results of statistical analysis seem also to confirm everyday experience Causes of trouble are multiple and complex—personality counts for more than environment, sexual difficulties are less intractable than those of character—and the broad results of "counselling" (a third helped, a third not helped, a third "result unknown") seem to justify the practitioner's misgiving when the history and symptoms of a sick marriage are laid before him

---

Cunningham's Manual of Practical Anatomy (12th ed Vol III, Head and Neck Brain London Oxford University Press 1958 Pp 520 28*s*)—The main changes in this new edition, revised by the late Prof J C Brash, concern nomenclature and illustrations Many, but not all, of the alterations approved at the International Congress of Anatomy in Paris in 1955 have been accepted in this text Alternative terms are clearly indicated Twenty-one drawings have been replaced, and so have many radiographic plates This familiar manual may be judged lengthy by present-day standards, but it is still, we think, the best available dissection manual Since so many students today pay little heed to large systematic textbooks, even if they own them, it is all the more desirable that they should use an adequate practical manual Though the practice of relying wholly or largely upon a dissection handbook is to be deplored, Cunningham's manual is perhaps the best of guide-books to the human body The new edition is bound in washable material, and preserves its customary handsome appearance

Cardiovascular Collapse in the Operating Room (London Pitman Medical Publishing Co 1958 Pp 197 45*s*)—Death comes most dramatically in the operating-theatre, partly because of its unexpectedness It is on this point that the authors of this book, Dr Herbert Natof and Prof Max Sadove, of the University of Illinois College of Medicine, have much to say, for the gist of their message is that such deaths are usually associated with demonstrable disease which should have been detected clinically and suitable precautions taken Each predisposing cause is carefully considered in a book which will interest surgeons as much as anæsthetists

Smoking, Lung Cancer and You (London Lindon Press 1958 P 72 5*s*)—This short, easily read book by Dr Robert N C McCurdy presents for the lay reader the main facts concerning the dangers of tobacco-smoking It is well and interestingly written from a strongly individual viewpoint by a medical officer of health who, after studying the problem of lung cancer both nationally and in his own area, feels that the time has come for Government action The argument is well documented and doctors as well as laymen should find it helpful in assessing the social and political as well as the statistical aspects of this pressing present-day problem

THE LANCET

LONDON 9 AUGUST 1958

Heart-lung Machines

SINCE the methods of extracorporeal circulation were first put to clinical use, many rival schools of technique have evolved, each with its ardent supporters. In the early days there was little to choose between them: each had its list of surviving patients, and the causes of mortality were often ill understood; each had its technique to perfect before machines could be accurately compared. There are two fundamental methods of oxygenating blood—by bubbling oxygen through it[1] and by exposing a film of it to oxygen. The film method is subdivided into systems which use rotating discs[2-4] and those incorporating the stationary vertical screen.[5] Though figures have been compiled at each of the big centres using these different methods, a straight comparison between them is difficult for several reasons: the cases may be selected differently, the technical accomplishment of surgeons varies, and their presentation of results is often hard to assess. There is also a hidden factor which bears directly on the success of the operation: the length of time required to close an intracardiac defect must always depend on the dexterity of the surgeon, but the ultimate security of the closure—i.e., freedom from recurrence—may well depend on taking a rather longer time than is commonly required for the intracardiac operation. It has been clearly shown by VARCO et al.[6] that the duration of perfusion at lower rates of flow directly affects the survival-rates of patients. At rates of flow between 56 and 65 ml. per kg. per min. the duration of perfusion was less important, although none of the perfusions lasted longer than an hour. These results with a bubble oxygenator may discourage surgeons from using this type of apparatus, especially in adults. Safety is clearly the first and vital need, but as pressure of work rises other considerations become increasingly important, and ease of cleaning, sterilisation, and maintenance, and manpower demands can all greatly influence the choice of machine.

For these reasons the paper by Dr. GERBODE and his colleagues on p. 284 is of much interest. It is an account of the clinical use by one surgeon of two filming machines using different principles: one a fixed vertical screen, a variant of the Gibbon, developed by OSBORN[7] in San Francisco; the other the rotating-disc oxygenator devised by MELROSE[2] at the Postgraduate Medical School and introduced into the operating-theatre at Hammersmith Hospital five years ago. Dr. GERBODE had previously decided that the film oxygenator was preferable to the bubble type. Now, since "no substantial difference in mortality or morbidity or any other measurable variable could be detected", considerations of convenience, cost, and administration have made Dr. GERBODE decide on the use of the Melrose machine only in future at Stanford University Hospital. In the cases recorded the original Melrose 'Perspex' oxygenator[2] was used. The material of the oxygenator and of the discs is now to be changed to permit autoclaving and the disposal of the discs: "these requirements are judged essential for the proper maintenance and safety of an apparatus used more than five times a week." This sentence may give a clue to one of the essentials for excellence in this work: for their successful performance these complex procedures require a frequently repeated, routine, standardised technique.

The paper from Stanford University, with its account not only of the advantages of the British machine but also of the routine safe use of elective cardiac arrest—another British advance—shows that British surgery has contributed generously to the common fund of knowledge in intracardiac surgery. It illustrates too how the provision of an efficient machine does not by itself ensure successful open-heart surgery. More important now is a highly trained medical and surgical team working with unremitting diligence, and having at its disposal ample means for preoperative investigation, first-class operating-theatre equipment and accommodation, and adequate provision for the immediate postoperative recovery period and later convalescence. Dr. GERBODE and his colleagues are to be congratulated on the figures they present. The series is not long by American standards but it is long enough to be entirely convincing. It is notable that he has lost only 3 out of 14 patients treated by an intracardiac operation for the tetralogy of Fallot, and some of the other complicated defects have been very successfully dealt with. We are glad to publish a record of this project which has been brought to so satisfying a conclusion by a joint team of American and British workers.

Hæmolytic Disease of the Newborn

IN the past ten years the infant mortality in England and Wales has fallen by half, largely owing to the improved treatment of infective illness. Today 80% of neonatal deaths are due to causes, such as immaturity and congenital deformity, which cannot yet be prevented. Consequently the 350 deaths due to hæmolytic disease assume considerable importance. It can be calculated that this disease also accounts for 500 of the 16,000 stillbirths each year.

Since the discovery of the rhesus factor by LANDSTEINER and WIENER[1] in 1940, great strides have been made in the understanding and management of this disease, and it is claimed that, with early diagnosis and exchange transfusion in selected cases, over 95% of affected infants that are born alive should survive.[2,3]

[3] Walker, W., Neligan, G. A. *Brit. med. J.* 1955, i, 681.

Yet there has been no substantial fall in mortality. Indeed it is estimated that some 200 infants die needlessly each year, and this was confirmed by WALKER and MOLLISON[4] in a study of deaths attributed to hæmolytic disease in England and Wales in the years 1953 and 1955. No new knowledge is required to prevent this loss of life—only the application of existing knowledge, which is set out in a memorandum of the Central Health Services Council which is being sent to all family doctors.[5] But hæmolytic disease not only contributes to the total of fœtal and neonatal deaths: it carries important, often poignant, implications for the families concerned. Therefore, though the risks of immunisation are small, even the first pregnancy in an Rh-negative woman calls for special obstetric care.

The importance of early diagnosis is now recognised, and the memorandum outlines a policy of blood-grouping tests designed to ensure antenatal prediction. But, since this will not always be achieved, it draws attention to the early symptoms which point to the diagnosis.

The measures recommended include the Rh grouping of all pregnant women and antibody tests at 32–36 weeks of pregnancy in all found to be Rh-negative. The collection of clotted cord blood from the infants of all Rh-negative women is also recommended, since a positive Coombs test will establish a diagnosis of hæmolytic disease. (On the other hand a negative result does not exclude all forms of this disease.) An alternative plan for antenatal prediction consists in the testing of all mothers for antibodies between 32 and 36 weeks of every pregnancy. It is claimed that by this plan, as one specimen is required from every mother in every pregnancy, testing is less likely to be overlooked, while a few cases of immunisation to rare antigens are detected antenatally. Which policy is followed will depend largely on local arrangements.

The memorandum rightly points out that jaundice in the first twenty-four hours of life is to be ascribed to hæmolytic disease until proved otherwise, and demands immediate admission to hospital. This applies even if the infant is firstborn, and even when the known blood-group background appears to exclude the diagnosis. If in addition there are pallor, bruising, enlargement of the liver, or other signs, admission is urgent. Jaundice appearing after the first day of life can sometimes become so intense as to cause brain damage; therefore deep jaundice in the first week of life requires expert opinion. Hæmolytic disease due to ABO incompatibility has been recognised with increasing frequency in recent years,[6] [7] but no single test establishes the diagnosis—the Coombs test is often negative. Antenatal prediction cannot be achieved with certainty, and consequently diagnosis is usually based on the results of many tests that are not easily interpreted. The true incidence is not known. VALENTINE[8] has studied a series of infants showing jaundice in the first day of life. In all cases there was an underlying hæmolytic anæmia; in a third this was Rh hæmolytic disease of the newborn, and in the remainder hæmolytic disease due to incompatibility within the ABO groups. Some workers claim that ABO hæmolytic disease is commoner than that due to rhesus factor, but, being milder,[9] presents a less important practical problem.

As the memorandum says, results are best in units with special experience, and if a unit is to provide really effective service it must carry out the necessary tests at any hour and be able to undertake transfusion within half an hour of birth. (We hope the statement that the "interval between birth and exchange transfusion should be as brief as possible" is not misinterpreted, for such urgent treatment is required only in very severely affected infants, and in most it is better to apply this treatment between four and eight hours after birth.) A calculation based on the fatal cases in 1953 and 1955[4] showed that each hospital concerned dealt, on average, with only twelve cases a year, whereas the memorandum suggests that to maintain the required standard each unit should deal with at least fifty cases a year.

A national trial reported in 1952[10] [11] suggested that spontaneous delivery resulted in less loss of life, fœtal and neonatal, than did routine premature induction. But experience has justified premature induction in families where a preceding infant has been very severely affected or stillborn. Some workers go further and recommend induction for all cases of Rh isoimmunisation,[12-14] but such a policy should not be adopted hastily. It could prevent at most sixteen stillbirths in a hundred cases treated in this way, against which must be set the risks of induction to both mothers and infants. In fact probably only eight stillbirths would be prevented, for almost half occur before 35 weeks' gestation, the time most commonly recommended for induction. If on the other hand stillbirth could be forecast with relative certainty, induction would be justified, for there is no convincing evidence that cortisone or any other drug is of value in this condition.

There is a correlation between maternal antibody titre and severity,[15] but it is doubtful whether this is so precise as to help in the management of individual cases. WALKER[16] claims that tests on liquor amnii enable severity to be forecast. This work requires confirmation and elaboration, but, alone or together with antibody titre, such tests may prove of real practical value.

Many problems may remain, but if the recommendations of the memorandum are applied the coming years may see as big a change in the mortality of hæmolytic disease of the newborn as antibiotics have brought about in some other diseases.

The Development of Respirators

IN 1947 Britain had her first big epidemic of poliomyelitis There were about 600 Both-type tank respirators in the country at that time, presented by Lord NUFFIELD in 1938–39, and they were invaluable for patients with respiratory weakness; but the epidemic revealed how inadequate were the country's resources for dealing with poliomyelitis Apart from a dearth of doctors and nurses with the necessary experience, the design of respirators had failed to advance with the times, and, what was worse, many respirators had become useless from lack of maintenance. Consequently, in 1948, the design of respirators attracted much interest, and the progress of the past ten years is now reviewed in the Medical Research Council's report.[1]

Tank respirators have not changed in principle, but improvements in detail have been of great practical importance. A choice of respiratory-rates was provided, more ports were placed in the side of the tank, and an inflator was included so that artificial respiration could be continued when the patient was withdrawn from the tank for nursing care When a patient was being put into an old respirator his head had to be delivered through a small opening in the front of the tank, a very cumbersome business, which was avoided by splitting the front into an upper half which could be raised and lowered, and a lower half which was fixed This great practical advance was introduced as one of a number of modifications to the Both respirators, which were thereby given a new lease of life The principle of splitting the front of the tank was carried to its logical conclusion by the development of an "alligator" respirator, first designed in Australia by BOTH and now made by at least two manufacturers in the United Kingdom In this the whole respirator is split horizontally and hinged at the foot, so that access to the patient is easy and the respirator can be brought into action again merely by closing the lid

Cuirass respirators which fit over the abdomen and chest have also been designed, and, though as respirators they leave much to be desired, their convenience makes them useful for the patient who needs respiratory assistance for part of the day or while asleep The Tunnicliffe breathing jacket[2] is a similar device that provides more efficient artificial respiration at some cost in convenience. A rocking bed is also in production and is specially suitable for weaning from artificial respiration those patients whose diaphragms have not recovered

The fundamental novelty of this period has been the introduction of intermittent positive-pressure respiration (I.P.P.R.) in Denmark in 1952 A rubber or sometimes metal tube is inserted through a tracheotomy, and an inflatable cuff around the tube ensures a good fit in the trachea, so that foreign material in the pharynx cannot get into the lungs, and air blown into the lungs cannot escape through the nose and mouth A tracheotomy is now considered essential in any patient with paralysis of swallowing as well as of respiration, and those with experience of acute paralysis increasingly favour a tracheotomy when in doubt In the presence of a tracheotomy I.P.P.R. is, in Europe at least, the usual means of artificial respiration Many positive-pressure respirators have now been designed with many different characteristics, and the most prominent of their merits should be robustness and reliability. In I.P.P.R. each respiration resembles a miniature Valsalva manœuvre in which the intrathoracic pressure is temporarily raised There is good evidence that in very sick animals this can reduce the venous return to the heart, and that this effect can be reversed by applying negative pressure between inspirations Some of the more recent I.P.P. respirators provide a negative-pressure phase, and clinical evidence should soon be forthcoming about their efficacy

It seems likely that the stage of intensive development of breathing machines is coming to an end, and that future research will deal with the physiological state of the patient receiving artificial respiration. A wide subject for inquiry is open here, dealing not only with the exchange of oxygen and carbon dioxide in the lungs but also with the mechanics of the lungs and chest wall, with particular reference to the effects of pressure changes on the circulation

Annotations

CANCER OF THE TONGUE

ONE of the problems that is likely to beset any surgeon interested in the operative treatment of cancer of the tongue is the small number of cases that come his way[1] This is, happily, one of the sites where the incidence of cancer seems, certainly in civilised societies, to be declining steeply—a fact difficult to reconcile with the view that cancer of the mouth and of the bronchus share tobacco as a common ætiological factor Added to this, there is an increasing tendency for all patients with mouth cancer to be channelled to the radiotherapist for their primary treatment. Accordingly it is surprising to read in the opening sentence of an appraisal of progress in surgical therapy by Danely P. Slaughter and his colleagues[2] in the University of Illinois "Somewhat over a decade has now elapsed since the surgical treatment of cancer of the tongue assumed a pre-eminent position in the over-all management of this disease." Later they admit that there is still little published evidence to sustain the claims of the surgeon in this field, but they cite unpublished data claiming a 36% five-year-cure rate in a small group of patients with regional lymph-node metastases

In the management of the tumour at the primary site the place of surgery is very much a matter of opinion; but to the view that, in general, neck metastases are best dealt with by block dissection radiotherapists usually subscribe Rather less than half the patients will be found at the outset to have no enlargement of the neck nodes, and in this type of case the expectant policy seems, in the main, to prevail, but Tailhefer,[3] from his very wide experience at the Fondation Curie, stated a strong case for prophylactic operation, claiming that his results were improved by this more energetic attack. It has now been

shown that, even where no enlarged nodes can be felt in the neck, in 40–60% of cases the nodes will be found at operation to contain microscopic metastases [3–5]

Surgical enthusiasts such as Hayes Martin [6] are now inclined to pin their faith in the cure of lingual cancer to a combined en-bloc resection of the primary tumour and the regional lymph-nodes, whether these are clinically involved or not, but he and his colleagues have displayed a not unnatural reluctance to practise prophylactic block dissection, believing that the risk of ultimate contralateral spread is 11% Slaughter [8] may be presumed to favour a more vigorous approach, since he believes the risk of such a happening to be less than 1%

Surgeons admit that this, or indeed any other, type of operation can have no place in the treatment of cancer of the posterior third of the tongue Moreover, even when surgery is undertaken under the most favourable circumstances, the chances of disappointment are considerable An apparently happy result is all too often marred by the appearance of a new primary (perhaps in 1 in 10 or more [7 8]), or a carefully conducted dissection is followed by the early appearance of seedling "recurrence" in the operation field In the prevention of this, there is perhaps relevance in the work of Southwick and Cole,[9] who in a careful study of the risk of local implantation following colon resection for cancer, showed very clearly the merit of scrupulous care in avoiding spillage of cancer cells

Consideration of the contending claims of surgery and of radiotherapy in the control of cancer of the tongue (or, for that matter, at any site in the mouth) is hampered by the lack of any good evidence on the usefulness of the two methods in comparable cases It is high time that exponents of the two approaches provided a firm answer based on shared experience

FAILURE OF DETERGENTS TO DISINFECT

IN 1935—the year in which he discovered that 'Prontosil' could cure experimental infections—Domagk described the first of a new class of surface-active chemicals with detergent and bactericidal properties The cationic members of this class are now widely used as disinfectants, and the most useful of them are the quaternary ammonium compounds It was very soon apparent that some organisms are sensitive to the sulphonamides and others resistant, but even now it is not always realised that there are similar differences in sensitivity of different bacteria to the action of the quaternary ammonium disinfectants Gram-positive cocci are much more sensitive to these agents than are gram-negative bacilli, *Pseudomonas pyocyanea* is relatively resistant In practice these disinfectants are used at concentrations which should suffice to kill even less sensitive bacteria, but under working conditions the effective concentration or the time of exposure may be so reduced that *Ps pyocyanea* will not be destroyed Plotkin and Austrian [10] have described the consequences of such a failure in disinfection

Fifteen patients in a New York hospital developed septicæmia after receiving intravenous transfusions Blood-cultures from every patient yielded the same organism—an unusual bacillus closely related to *Ps pyocyanea* This finding prompted a full investigation of all materials used in intravenous transfusions, and it was found that swabs for disinfecting the skin before injection, which were stored in disinfectant, were contaminated with the same organism The disinfectant was a 0 1% solution of 'Zephiran', a quaternary ammonium compound widely used in North America Before each intravenous injection the skin had been smeared with what was in effect a culture of live bacteria It is known that cationic detergents are adsorbed readily to cotton fibres,[11] and this appears to have been the way in which the concentration of zephiran was reduced below that necessary to kill *Ps pyocyanea* and related bacteria Last year Keown et al [12] reported five deaths from *Ps pyocyanea* septicæmia after cardiac operations, the source of the infection being a heart-lung machine supposedly sterilised with 0 1% zephiran [12] Lowbury cultured *Ps pyocyanea* from bottles of 1% cetrimide in use in a British hospital [13] The organisms survived in the corks, and substitution of screw-caps for corks in disinfectant bottles greatly reduced the number of *Ps pyocyanea* infections in this particular hospital Anderson and Keynes [14] have shown that extraction of the cork releases a shower of infected cork dust into the bottle Organisms from this dust may cause wound infection if the disinfectant is used immediately after being poured out—before the organism has been exposed to disinfectant long enough to be killed

Practical lessons may be learnt from these mishaps Disinfectants should not be dispensed in bottles with corks Gauze and cotton-wool swabs should not be sterilised and stored in disinfectant but should be sterilised in a pressure-steam steriliser Complex apparatus which cannot be heated is probably best sterilised with ethylene-oxide gas [15] Quaternary ammonium compounds are not very satisfactory skin disinfectants As we pointed out some years ago, the most effective disinfectant for this purpose is still 2% iodine in 70% spirit [16]

In short, quaternary ammonium disinfectants should be used with some discretion, in the knowledge that in their action on bacteria they resemble the sulphonamides more than the autoclave

HOMOTRANSPLANTATION OF THYROID IN UNIOVULAR TWINS

WHEN it became evident that myxœdema and cretinism were due to thyroid deficiency the first proposal for treatment was that a healthy thyroid should be transplanted into the affected person Horsley [17] in 1890 suggested that the thyroid of a sheep might be used for this purpose, and this suggestion was carried out by Bettencourt and Serrano [18] in the same year Horsley [19] recorded that even earlier both Bircher and Kocher had treated cachexia strumipriva by implanting fragments of goitre from another person into the patient's abdominal cavity We now know that attempts to graft tissue from another species, or even from another human being, are immunologically futile

As would be predicted, these early transplantation experiments were followed by only temporary clinical improvement, and their only importance is that they led directly to Murray's demonstration of the effectiveness of thyroid extract in the treatment of myxœdema When tablets of dried thyroid extract came into common use, interest in the possibilities of transplantation lapsed It seemed difficult to imagine any treatment simpler and

more completely effective than oral replacement therapy Yet fatal cases of myxœdema still occur [20], the usual sequence of events seems to be that patients correctly diagnosed and treated in the first instance become careless in time about taking their tablets and eventually pass into a state of severe myxœdema which is therapeutically irreversible For the most part such cases have occurred in people living alone with no-one at hand to remind them of the need for taking tablets It is evident that a successful thyroid graft would be a complete protection against this unhappy sequence of events, and it therefore seems worth reviewing again the possibilities of transplantation

The work of P B Medawar and his school on immunological tolerance has shown that homotransplants have no hope of survival unless the recipient has been prepared by the injection of the relevant antigens during fœtal or very early postnatal life How early this would have to be in man is uncertain, but a homotransplant might possibly survive if implanted in the first few weeks of life It is unfortunately difficult to diagnose cretinism at any age less than about 3 months, but the combination of astute clinical observation and modern tests of thyroid function might establish the diagnosis in a few isolated cases If this could be done before the patient reached the age of 1 month, transplantation of a piece of thyroid from another person might be worth attempting

At any later age homotransplants will certainly fail to take, with the single exception of one taken from an identical twin Fortunately when one uniovular twin is cretinous the other is usually normal, and this was so in the case described by Harnack et al [21] The healthy twin, Marina, had a normal uptake of radio-iodine, but her cretinous sister, Christiane, had only a trivial uptake in a minute fragment of thyroid tissue at the base of the tongue When the twins were 7½ years old the greater part of one lobe of Marina's thyroid was removed at operation and inserted in two pieces in Christiane's neck, one on each side, deep to the sternomastoids The early clinical effects were not striking, and three months after the operation Christiane again required oral thyroid treatment But a year later, thyroid was stopped without an immediate decline into hypothyroidism. Radio-iodine tests after administration of thyroid-stimulating hormone showed that the child now had useful, though still greatly subnormal, thyroid function It seems likely that the bulk of the implanted thyroid must have died shortly after the operation, but that enough remained for regeneration to occur Further observation will be required before we know whether the fragments will supply all the child's requirements of hormone

ENTEROPATHOGENIC ORPHANS?

IN 1956 a conference was held in New York on Viruses in Search of Disease [22]—an unusual topic It is, in fact, an important one, because so many viruses are now being isolated from the intestines of healthy people 47 of these "enteroviruses" [23] are known—3 types of poliovirus, 19 of Coxsackie A, 5 of Coxsackie B, and 20 of the enteric cytopathogenic human orphan (ECHO) group —and there is no reason to think that the list will end here Some are already firmly associated with disease poliovirus, Coxsackie virus, and some types of ECHO virus which cause aseptic meningitis Ramos-Alvarez and Sabin [24] have studied their association with summer diarrhœa of infants and very young children

They describe an epidemiological study in which a comparison was made between the viruses and bacteria isolated from the fæces of 153 children with diarrhœa and of 100 healthy children of the same age, district, and socioeconomic background Material from rectal swabs was used to inoculate monkey-kidney tissue cultures and newborn mice Cultures were also made for pathogenic bacteria, and paired sera were tested from 24 of the patients who had positive stools While enteroviruses were isolated from 20% of the healthy children, they were present in about 50% of those with diarrhœa This difference lay largely with the ECHO viruses, which were six times commoner in the test group than in the controls The prevalence of poliovirus and Coxsackie virus (about 3%) was the same in both groups 7% of the patients carried salmonella or shigella, which were not isolated from the healthy children, but there was no significant difference in the rates for pathogenic strains of *Escherichia coli* In all the cases where the serum was examined there was a rise in titre to the virus which was isolated from the rectal swab This proves that the virus in the fæces was causing an active infection when the child was ill, but does not prove that this infection was the cause of the symptoms

The evidence in this paper certainly suggests that the ECHO viruses may be a cause of summer diarrhœa But great care has to be taken before claiming that an enterovirus is a cause of disease These agents are isolated so often from healthy children that it would be surprising if they were not found also in the fæces of those with diarrhœa from other causes Mixed infections may occur, or infection with agents which we cannot detect by existing techniques It is difficult to exclude completely the possibility that viruses may arise from the cells or serum used in the tissue culture Yet another difficulty lies in the nature of the disease As Ramos-Alvarez and Sabin remark, "Summer diarrhœa of very young children is not a clinical entity but rather a consequence of transitory infection with a large variety of bacterial and viral pathogens" Even in the ECHO group no particular type seems to be associated with the disease In this study the viruses isolated were distributed among thirteen different serological types But Ramos-Alvarez and Sabin cite an outbreak of diarrhœa among infants in hospital described by Eichenwald et al [25] which was apparently caused solely by ECHO virus type 18 Possibly when we know more about the group some epidemiological pattern may emerge, as it has with the staphylococci and pathogenic *Esch coli*

The first report of the committee on the ECHO viruses in 1955 [26] stated that, as soon as one of these viruses was established as the cause of a clinically distinct disease, it should be removed from the group—which is probably a heterogeneous one anyway Although associations are being demonstrated between ECHO viruses and disease, they do not appear to be clear-cut enough to justify the removal of these agents from the "orphanage" The name ECHO has been acquiring a meaning in its own right as the meaning of the initials is forgotten [27], it seems likely that the name "orphan viruses", applied by Duran-Reynals "at a moment of conviviality",[26] will persist

BIOCHEMICAL CONCEPTS OF SCHIZOPHRENIA *

J R SMYTHIES
M A, M D Cantab, M Sc Brit Columbia, D P M
PSYCHIATRIST II AND PRINCIPAL INVESTIGATOR,
THUDICHUM PSYCHIATRIC RESEARCH LABORATORY, GALESBURG STATE RESEARCH HOSPITAL, GALESBURG, ILLINOIS

THE demonstration of the organic basis of general paralysis led, about fifty years ago, to the hope that schizophrenia might also prove to be caused by some easily distinguishable organic agent or condition The discovery that psychoses or mental deficiency could be caused by avitaminosis, hormonal imbalance, and specific disorders of metabolism, such as phenylketonuria, lent weight to the belief that schizophrenia might also be due to some metabolic or endocrine disorder, but the persistent failure to demonstrate any such organic basis led to a slackening of the momentum behind this approach and to the gradual dominance of the belief, among psychiatrists in North America at any rate, that the ætiology of schizophrenia was essentially psychological

A physiological interpretation of this psychological hypothesis may be put as follows everyone would agree that severe emotional trauma can lead to behavioural disturbances The psychological theories hold that schizophrenia may be explained by a logical extension of this, coloured by the discovery that emotional and other allied psychological factors can continue to interact and to act as causal agents when they are no longer present in consciousness, for this is what the Freudian theory of the unconscious amounts to Psychoanalysis holds that the causes of the illness lie in faulty early training and interpersonal relationship Its physiological basis is supposed merely to consist of those mechanisms whereby *any* past experience affects present emotional experience, motivation, and behaviour, reacting in this case to an involved and scarifying series of noxious experiences The warping of the child's psychological development is held to be a sufficient explanation of the adult schizophrenic The schizophrenic is withdrawn *because* the early environment forced the child to withdraw, and no specific metabolic fault is held to be involved

However, we now have a considerable body of evidence against this hypothesis, for organic changes have been discovered in schizophrenia that are certainly relevant to its ætiology, and progress has been made in constructing plausible hypotheses to explain these biochemical and pathological findings, but this does not lead us to reject the importance of psychological factors, as we shall see

The evidence for a genetic cause of schizophrenia is now generally agreed to be overwhelming, although the exact details may not yet be known Kallmann (1953) has accumulated a large body of evidence favouring the hypothesis that single-factor inheritance of the recessive type is the genetic cause of schizophrenia There are also more specific physiological findings The metabolic theories of schizophrenia have been focused on the idea of some cerebral toxin produced by faulty metabolism Equally possible are the lack of a necessary factor and the imbalance between two complementary mechanisms

An early proponent of such a view was Jung (cited by Osmond 1957) with his " toxin X "

Mann and Quastel (1940) proposed that a toxic amine might be responsible, and a popular idea of that time was that toxic amines from the gut might be involved—an idea that did not prove fruitful in this field but has found application in another following the work of Sherlock et al (1954), who showed that venous blood derived from the gut and bypassing the liver can produce psychotic effects

Buscaino (1952) introduced the concept of a toxic indole as causing schizophrenia, which idea is again fashionable

Broad Biochemical Investigations

In the absence of any specific directing hypothesis a large number of biochemical investigations were made on a wide front in the hope of turning up some clue that might suggest the cause Many of these reports were negative or contradictory, and the validity of others was doubtful either because the tests used were unreliable or because the findings might well be explained by the poor diet, concomitant medication, lack of motility, &c, of schizophrenics

Out of all this work the only findings that seem reliable are as follows

(1) *Liver function* —Richter (1957) states that there appears to be some impairment of liver function in schizophrenics as a whole, but there is no evidence that it is an invariable or obligatory concomitant However, Richter emphasises the possibility that different enzyme systems in the liver may be affected to different degrees, and concludes that we cannot yet exclude the possibility that in schizophrenics some of the functions of the liver may be seriously impaired

(2) *Toxicity of body fluids* —The blood of schizophrenics has been reported to be toxic to tadpoles (Fischer 1953) and to fibroblasts grown in tissue culture (Fedoroff and Hoffer 1956), but the latter workers find a similar degree of toxicity in patients undergoing surgery, suggesting that a non-specific response to stress of the kind described below may be involved Reider (1957), using Witt's elegant spider-web technique, has shown that extracts from schizophrenic urine produce significant abnormalities in the web-spinning behaviour of spiders similar to those produced by hallucinogens

(3) *Reaction to stress* —Various measurements have been made of the response (pulse-rate, blood-pressure, skin circulation, and response to adrenaline) to stress (Finkelman and Stephens 1936, Pfister 1938) These show that chronic schizophrenics are less reactive than healthy people Increased excretion of 17-ketosteroids has been found only in paranoid schizophrenia (Sands 1957)

(4) *Circulatory system* —Careful observations have shown that schizophrenics exhibit a mild but consistent degree of hypotension and a constriction of the small arterioles of the skin, leading to cyanosis (Shattock 1950) This is also evidence of a disorder of capillary structure (Lovett Doust 1955)

(5) *Metabolism of nitrogen* —Nitrogen is retained in recurrent catatonia, but this condition is rare and may not be related ætiologically to the bulk of cases of schizophrenia

(6) *Metabolism of phosphorus* —Örström and Skaug (1950) found a diminished turnover of adenosine triphosphate in schizophrenics, and Örström (1951) reported a higher content of phosphoglycollic acid in their red blood-cells

(7) *Abnormalities in brain* —This work is still in its early stages, but Ashby (1950) has reported that the activity of carbonic anhydrase is abnormal in schizophrenia Normally the activity of this enzyme is greatest in the occipital cortex and least in the temporal region, but in schizophrenia the normal topographical pattern was obliterated, except in some early cases, where there was a reduction in the frontal region Birkhauser (1941) reported a lower activity of monoamine oxidase than normal in the pallidum of schizophrenic subjects

(8) *Homœostasis* —If a large series of measurements is made of basal metabolic rate, circulation-rate, body temperature,

---

* Based on seminars held at the University of Iowa, March 1, 1958, and at Emory University, April 29, 1958

excretion of 17-ketosteroids, thyroid activity, and water metabolism in schizophrenics and in healthy people, it will be found that the variance of these readings will be greater in the schizophrenics This suggests that a concomitant of schizophrenia is some disorder of homœostasis

(9) *Other disorders* have been reported, such as disordered excretion of various substances in the urine—e g , sulphur compounds (Koch and Mann 1909), phenolic derivatives (Richter 1957), indoles (Riegelhaupt 1956), imidazoles (Stewart 1930), and aromatic substances (McGeer et al 1956)—but this very variety suggests that these compounds arise from increased bacterial action in the gut from some local cause such as stasis rather than a specific metabolism of schizophrenia

In summary, therefore, those investigations not directed by a specific hypothesis lead only to the certain deductions of a disordered response to stress, a disordered homœostasis, a probably non-specific toxicity of body fluids, a disorder of nitrogen metabolism in a certain rare kind of schizophrenia, and specific disorders of phosphorus metabolism and of cerebral carbonic-anhydrase and amine oxidase function These empirical findings do not suggest any specific theory but only that the biochemical mechanisms of the response to stress and of homœostasis are involved

First Specific Biochemical Theory

The first specific[1] biochemical theory of schizophrenia was put forward by Osmond and Smythies (1952) and was stated in a more specific form by Hoffer et al (1954)

Search for Toxic Metabolite

These workers applied a form of Koch's postulates adapted to a metabolic illness These postulates require us to isolate from schizophrenics a metabolite which, injected into healthy people, would reproduce the symptoms of schizophrenia This metabolite should either be found de novo in schizophrenics, or at least in significantly larger amounts in schizophrenics than in healthy people, or possibly the schizophrenic may be abnormally sensitive to the metabolite Contributory evidence should be obtained by showing other toxic properties of the metabolite or by testing for its presence in a deductive manner

But what metabolic fault should one look for in schizophrenia? There are millions of possible faults—which one should we choose? We approached this problem by asking a series of questions The first was What known chemicals are there that produce in healthy people effects closest to the symptoms of schizophrenia? We delineated a class of chemicals, including mescaline and lysergic acid diethylamide (L S D), that had this property and we called them "hallucinogens" We did not claim that these compounds produce exactly the signs and symptoms of schizophrenia The differences in temporal and situational factors will always preclude the exact matching of an experimental and a natural psychosis However, for our purpose what was required was the closest known analogy

We next asked which of these substances or any substance nearly related thereto could conceivably be formed in bodily metabolism, and we pointed to the close chemical relationship between mescaline and adrenaline, which suggested that derivatives of adrenaline might be strong candidates for the role of "M substance"—the mescaline-like toxin of schizophrenia Our hypothesis does not necessarily involve indoles except in so far that certain metabolites of adrenaline are indoles, our hypothesis is specifically directed towards metabolites of adrenaline and allied compounds

Harley-Mason (cited by Osmond and Smythies 1952) suggested one specific mechanism whereby a closer mescaline analogue than adrenaline could be produced in the body—i e , methylation of the phenolic groups of adrenaline—a reaction that Axelrod (1957) has found taking place in the body The finding by Resnick et al (1958) that adrenaline is *predominantly* detoxified by *o*-methylation in humans brings Harley-Mason's hypothesis of an excessive methylation back into prominence A possible fault might be the production in schizophrenia of the possibly psychotomimetic dimethoxy derivative of adrenaline The comparative amount of *o*-methylation in schizophrenics and normals should be measured a lesser degree in schizophrenics might suggest that some of the adrenaline was being metabolised by the adrenochrome pathway This hypothesis could easily be tested

Adrenochrome

Dr Eric Asquith, an anæsthetist at Regina General Hospital, told us that he had obtained psychotic reactions by giving patients injections of "pink adrenaline," which is a red mixture of oxidised products of adrenaline Since then Hoffer and Osmond (1958) have made an extensive study of a psychosis lasting a month and produced by the self-administration of "pink adrenaline" (to which adrenaline turns slowly on mere exposure to the air) for this length of time by an asthmatic; and H E Himwich (personal communication) has told us that he has observed an injection of adrenaline 1 mg to produce severe temporary personality changes of a paranoid type in a healthy person So we suggested that M substance might be adrenochrome, adrenolutine, or some other close relation among the many closely allied immediate oxidation products of adrenaline This hypothesis led to a number of experiments and observations

Some solutions of oxidation products of adrenaline have been reported to produce psychological disturbances in healthy volunteers, whereas others did not The difficulty here is that adrenochrome is very unstable and extremely reactive Thus in most cases it is probable that a mixture of substance has been injected and that adrenochrome is quickly changed into other substances once it gets into the body

Hoffer (1957a) has published observations on the more stable adrenolutine (trihydroxy N-methyl indole, an isomer of adrenochrome) By a double-blind technique he tried to determine which persons had had the adrenolutine and which had had the placebo

This he was unable to do at first as the P value of his result was only 0 1 In a later experiment (Hoffer 1957b) he succeeded in doing this with a P value of 0 02 However, in a third experiment (Hoffer 1957b) done in the three months following the last experiment, he again failed to make a significant prediction This probably means that the adrenolutine had deteriorated by this time, but of course, strictly speaking, chi-square should always be calculated for the whole of such a series to avoid the charge of selection of data Chi-square for the whole series did not reach significant values (P=0 2), but the majority of successful predictions came during the first month, thus suggesting a deterioration of the adrenolutine Hoffer is repeating these experiments, using a pure sample of adrenolutine

Another difficulty is one common to all tests that may be made of any drug to see whether it produces symptoms resembling psychosis, and that is the design of the experiment.

---

[1] Where a single compound, or a *small* group of compounds, or a specific biochemical mechanism is specifically implicated in the causation of schizophrenia

Pilot experiments will be needed to test the range of the apparently effective dose, to look for the type of response to expect, and to spot any undesirable complications The actual evaluation of psychotomimetic properties of a drug then depends on a properly designed double-blind experiment in view of what we now know of the extraordinary range of placebo reactions that can occur (Trouton 1958) Now that the pure forms of these compounds are, through the efforts of Heacock et al (1958), at last available, we can proceed to properly designed evaluation of stable compounds in the adrenaline oxidation series

Gastaldi et al (1957) were unable to produce such symptoms with pure adrenochrome, but they did not appear to use the careful psychological testing methods of Hoffer (1957 and b)

We found no change in behaviour in mice, even after such a large intraperitoneal dose as 40 mg per kg of body-weight, and S Martens (personal communication) has found none in monkeys

Species differences are important in this field, however, particularly in the case of those higher social, intellectual, and emotional functions that are affected in schizophrenia and hardly play any prominent part in the lives of mice or even monkeys Possibly the enzyme systems that control these higher functions may hardly be developed in the lower mammals Thus evidence from non-human sources about substances producing symptoms resembling psychosis needs to be assessed with caution However, it is quite possible that adrenochrome is not such a substance but that one of its precursors or derivatives may be

The work of Professor P Holtz and Dr G Taubmann (personal communication) has thrown some light on this They have found that freshly prepared adrenochrome does not produce symptoms resembling psychosis, but, if it is first oxidised by shaking with normal human serum in air, the resultant liquid (deproteinised) will produce symptoms of psychosis if given sublingually Furthermore, pure adrenochrome does not inhibit glutamic-acid decarboxylase whereas the oxidised form is a potent inhibitor of this important enzyme which produces the aminoacid G A B A (γ-aminobutyric acid) thought to be concerned with synaptic inhibition in the brain This is the first confirmation to date of the work of the Saskatchewan group on humans

Schwarz et al (1956) report that intraventricular adrenochrome produces a drowsy state in monkeys with insensitivity to painful stimuli, as does intraventricular adrenaline, and Witt (1954) has produced abnormalities in the web-spinning of spiders by its use

Adrenochrome is certainly highly active chemically Meyerhof and Randall (1948) showed that it strongly inhibits the important enzymes hexokinase and phosphohexokinase concerned in the metabolism of glucose in the brain, and Abood and Romanchek (1957) have shown that it has "a formidable effect on phosphorylation processes"

Adrenochrome is so unstable and so biologically active that, if it is introduced into the blood-stream, none may survive unchanged by the time it reaches the brain

Furthermore there is a general point concerning the relevance of the blood-levels of internally produced derivatives of adrenaline to psychosis If noradrenaline and adrenaline are both neurohumours, mechanisms for their formation and destruction must be present close to their sites of action in the brain substance If, therefore, the metabolism of these substances leads to the production of toxic substances, these latter can be produced locally in the brain and there give rise to symptoms resembling psychosis without having to enter the blood, or the end-product that does appear in the blood may be non-toxic An allied argument has been presented by Shore et al (1957a)

Clearly, much more basic work is needed on the metabolism of adrenaline both in the brain and in the rest of the body in both healthy people and schizophrenics There is, however, some indirect evidence

Lea (1955) argued that, since adrenochrome is an antihistamine, if schizophrenics had large amounts of circulating adrenochrome in their bodies they should be less susceptible to allergic conditions He made a careful study of schizophrenics in British Army records, using head-injured patients as controls, and showed that there was a highly significant deficiency ($P > 0\ 001$) of schizophrenics with allergic conditions A similar finding has been published by Ehrentheil (1957), Swartz and Semrad (1951), and other workers in America This finding also fits in with Lucy's (1954) observation that the histamine tolerance of schizophrenics is increased

This cannot, however, be necessarily taken as evidence that adrenochrome is the responsible agent in schizophrenia, because it may merely represent an end-product of the disordered cerebral metabolism of adrenaline, and some such earlier product as the quinone derivative of adrenaline (2-methylamino-ethanol-quinone) might be the actual toxin, as described above Rinkel et al (1954) suggest that adrenoxine, yet another oxidative product of adrenaline, is the responsible toxin

More recent work, however, runs against this hypothesis Resnick et al (1958) show that, in man, practically all the infused β-labelled adrenaline can be recovered from the urine mostly as 3-methoxy-4-hydroxy-mandelic acid

Holland et al (1958) measured equilibrium plasma concentrations of adrenaline and noradrenaline and detected no difference between healthy people and schizophrenics as regards the rates of utilisation of circulating adrenaline and noradrenaline

Axelrod (1958) has been unable to detect any adrenochrome in normal or schizophrenic plasma

Supportive evidence, however, for the hypothesis of deranged function of adrenaline in schizophrenics comes from Walaszek et al (1958), who found that the serum of schizophrenics either abolished or reversed the systemic vasopressor response produced by the topical application of adrenaline to the exposed cerebral cortex, the serum of healthy people had no such effect They also found that rabbit brain premedicated with the serum of schizophrenics gave significantly higher values for adrenaline and noradrenaline than did similar assays of brain tissue from rabbits pretreated with serum from healthy people

Taraxein

The next development came from Heath's group in New Orleans Following our suggestions about the possible role of oxidation products of adrenaline in schizophrenia, these workers supposed that the serum of schizophrenics might oxidise adrenaline faster than does the serum of healthy people Leach and Heath (1956) confirmed this hypothesis experimentally, and Hoffer and Kenyon (1957) showed that the substance produced was adrenolutine Heath et al (1958) by a brilliant series of researches isolated a factor, present in the serum of schizophrenics but absent from that of healthy people, which, they reported, would reproduce clearcut symptoms of schizophrenia when injected into healthy people They called this factor taraxein The films showing these reactions are certainly impressive, but confirmation by an independent group is still required

What is the chemical nature of taraxein? Heath's group also showed that blood-ceruloplasmin levels are raised in schizophrenia to such values as are found in pregnancy, chronic sepsis, and terminal carcinomatosis

The level of blood-ceruloplasmin (measured by blood-copper) shows a positive correlation with the spontaneous remission-rate and a negative correlation with the chronicity of schizophrenia As psychotic patients begin to improve clinically, the blood-copper level falls rapidly So, clearly, the raising of the blood-ceruloplasmin level cannot be the cause of the schizophrenic reaction In any case the high levels of blood-ceruloplasmin are also found in the other conditions of chronic somatic stress listed above Hence ceruloplasmin appears to provide some protective mechanism against this stress, possibly as a method of detoxifying the excess of adrenaline produced in a severe reaction to stress

The raised blood-ceruloplasmin of schizophrenics has been confirmed by Abood et al (1957) There is, however, considerable overlap with normals and Ostfeld et al (1958) showed that ceruloplasmin levels are raised by any state of emotional stress

But the relation of taraxein to ceruloplasmin remains obscure, beyond the fact that taraxein is probably a globulin, according to S Martens (personal communication), who has also found that adrenolutine in large doses produces a state similar to that evoked by taraxein In animals premedication with taraxein or L S D potentiates the effect of adrenolutine about tenfold This suggests that these substances either interfere with the breakdown of adrenolutine or its binding, or sensitise the tissues to the action of adrenolutine much as L S D potentiates the effect of adrenaline

Hoagland (1957) reports important biochemical similarities between schizophrenics and healthy people who have taken L S D Schizophrenics react to corticotrophin by a smaller increase than do healthy people in their excretion of 17-ketosteroids, sodium, potassium, and uric acid but by a larger increase in that of inorganic phosphate Healthy people show similar changes after the administration of L S D Hoagland therefore suggests that both L S D and the toxic metabolite of schizophrenia facilitate the conjugation of inorganic phosphorus with organic substances or slow the rate of turnover of phosphorus This suggestion is supported by the observation of Abood and Romanchek (1957) that adrenochrome has a formidable effect on phosphorylation processes Furthermore Hoagland (1957) reports that schizophrenics do not excrete adrenaline after the administration of L S D whereas healthy people do

Second Specific Biochemical Theory

The second specific biochemical theory of schizophrenia was put forward by Woolley and Shaw (1954) This was based on the observation that L S D , which is the most powerful hallucinogen known, is also a potent antagonist of serotonin when tested on smooth muscle, blood-pressure, &c Therefore Woolley and Shaw supposed that its hallucinogenic effects might be due to its interference with the action of serotonin in the brain

Serotonin has been discovered in the brain, particularly in the phylogenetically older areas, such as the hypothalamus (Bogdanski et al 1957, Costa and Aprison 1958) The enzyme 5-hydroxytryptophan decarboxylase, which synthesises serotonin, and monoamine oxidase, which destroys it, have also been found in the brain, also in highest concentration in the hypothalamic areas Brodie and Shore (1957) and others have suggested that serotonin is an important chemical mediator in the nervous system It is therefore understandable that either an excess of serotonin or a lack of it might lead to mental dysfunction If serotonin acts by depolarisation of nerve-cells, too much of it would lead to a permanent state of depolarisation, and thus no impulses could be transmitted, and too little of it would lead again to an absence of impulses

Other findings are also relevant to this hypothesis An early criticism was that the brom derivative of L S D ('B O L 148') is also an antagonist of serotonin but is not hallucinogenic Chlorpromazine is also a powerful anti-serotonin and, so far from being hallucinogenic, is powerfully antihallucinogenic However, it is of course possible that L S D and B O L may have the same effect on the peripheral reactions and a different effect on the central nervous system

A second criticism has a quantitative basis It has been calculated that during the period of hallucinations in man there is in the brain less than 0 000001 mg of L S D per g of brain substance (Axelrod et al 1957), and in this very low concentration L S D actually potentiates serotonin (Costa 1956) However, the possibility remains that L S D produces some of its mental effects by potentiating serotonin rather than by antagonising it

Serotonin does not produce any effects on injection but it probably crosses the blood-brain barrier only very slowly The precursor of serotonin (5-hydroxytryptophan) can be given instead, and this readily crosses the blood-brain barrier and is transformed into serotonin in the brain and causes a great rise in the brain-serotonin level It also causes in dogs behaviour disturbances similar to those caused by L S D (Udenfriend et al 1956)

Bufotenin, which is chemically very closely related to serotonin and is pharmacologically almost indistinguishable from it, is a very potent hallucinogen and produces symptoms resembling psychosis There is an important difference, however, in that 5-hydroxytryptophan produces a sleep type of electroencephalogram and L S D an arousal type, indicating different methods of action of the two drugs (Costa and Rinaldi 1958) In other words, it is unlikely that they both work merely by raising the brain-serotonin level

Another aspect of this problem has been emphasised by Costa (1956), who has found that the power of many drugs to produce symptoms resembling psychosis quantitatively parallels their power to potentiate the reaction of the cat's nictitating membrane to adrenaline Furthermore, bufotenin has a much stronger effect than serotonin, and lysergic acid diethylamide sixty-five times the effect of B O L

Another argument in favour of the serotonin hypothesis is the fact that reserpine depletes the brain of its store of serotonin (Shore et al 1957b), and its tranquillising effect parallels in time the time course of this depletion and not the time course of the mere presence of reserpine in the brain Reserpine actually frees serotonin from a bound form to a free form in the brain, and this free form is rapidly metabolised by amine oxidase L S D inhibits the destruction of serotonin by amine oxidase (Hoagland 1957) and thus may cause the brain-serotonin level to rise, although a rise in the level of the bound form may be necessary for the production of symptoms resembling psychosis However, reserpine can be counteracted by giving dopamine and thus restoring the levels of catechol amines (Carlsson et al 1957) but not by giving 5-hydroxytryptophan alone (and thus restoring the level of serotonin) The effect of these two precursors show summation if they are given together This suggests that the effects of reserpine are mediated both through its effects on brain serotonin and catechol amines but more strongly through the latter

Zeller (1958) has reported a derangement of tryptophan metabolism in schizophrenia In a tryptophan-load test schizophrenics will excrete more xanthurenic acid and less 5-hydroxyindoleacetic acid than normals The difference was statistically significant. Serotonin is a derivative of tryptophan

Third Specific Biochemical Theory

The third specific biochemical theory of schizophrenia implicates the metabolism of acetylcholine in the brain Different aspects of this hypothesis have been put forward by Hoffer (1957a) and Pfeiffer and Jenney (1957) The latter argue from the facts that (1) many tranquillisers have persistent acetylcholine-like effects, (2) drugs which show the nicotinic properties of acetylcholine—e g, di-isopropyl fluorophosphate—make schizophrenics worse, and (3) drugs which show muscarinic effects—e g, arecoline—make them better Therefore drugs which alter the level and activity of acetylcholine in the brain can alter the clinical state of the schizophrenic, and low levels of acetylcholine might be expected in schizophrenic brains Administration of a precursor of acetylcholine has been reported to benefit chronic schizophrenics (Pfeiffer et al 1957) A disorder of acetylcholine function may be secondary to an upset of adrenaline function, because adrenochrome is an anti-cholinesterase (Hoffer 1957a) One can also speculate that the metabolism of serotonin may also give rise to drugs which produce symptoms resembling psychosis, because its oxidation gives rise to a red substance chemically allied to adrenochrome

Patzig and Block (1953) have found that injected mescaline (incorporating ^{14}C) is rapidly bound to liver protein and that, during the period (in mice) corresponding in time to the period of hallucination in man, very little mescaline was found in the brain They suggested that this transformed mescaline was the cause of the mental symptoms, and that schizophrenia might be associated with a faulty hepatic detoxication of endogenous toxins The absorption of the mescaline on to liver protein may block sites of detoxication of some endogenously produced toxin Working on this hypothesis Harley-Mason et al (1957) looked for metabolites either of mescaline or of abnormal bodily metabolism in the urine of healthy volunteers who had taken mescaline A new metabolite of mescaline (3 methoxy, 4–5 dihydroxyphenylacetic acid) was discovered but was thought unlikely to cause mescaline psychosis

Conclusion

The general concept of schizophrenia that arises from the facts at present at our disposal is that it is a genetically determined disorder of the metabolism of the neurohumours of the central nervous system—noradrenaline and adrenaline, serotonin and/or acetylcholine The cause of schizophrenia may be a primary genetically determined fault in one of these systems—e g, the production of toxic oxidative metabolites of adrenaline, which would disrupt the normal functions of the brain through their actions on key enzyme systems, such as hexokinase and phosphorylation mechanisms, as well as their actions on the metabolism of the other neurohumours, such as the action of adrenochrome on cholinesterase On the other hand, the different clinical pictures of schizophrenia may result from different genetically determined faults in more than one of these systems, producing, through the interaction of these systems, allied clinical pictures

There remain two advantages of the concept of the primary fault in the metabolism of adrenaline The clinical course of schizophrenia strongly suggests by its indolent chronicity the operation of a vicious circle The adrenaline-derivative hypothesis offers the possibility of two such vicious circles (see below), it also offers an explanation of the clinical correlation of the disease with stress of some kind

It is well recognised that the onset of schizophrenia is commonly linked to some specific stress, perhaps a battle stress, or emotional, interpersonal, or biological stress Such stress situations will be associated with a chronic overactivity of the sympathetic system, and it is to be expected that any latent faults in this system would become apparent at this time

This is where the first vicious circle comes in The production, by the metabolism of adrenaline, of end-products which cause symptoms resembling psychosis will lead to further stress because the experience of the effects of these end-products is also stressful, as anyone who has experienced the appalling effects of mescaline and sympathetic overactivity combined, as I have, can testify This further stress will lead to the production of further activity in the sympathetic nervous system and thus more adrenaline, more toxic breakdown products of this adrenaline, and so, in turn, more stress, thus constituting the vicious circle

The second possible vicious circle is constituted by the anti-cholinesterase effect of adrenochrome (Hoffer 1957a). The raised level of activity of the sympathetic ganglia (which are cholinergic) thereby occasioned will lead to an increased output of adrenaline and so of the toxins which may be responsible for schizophrenia

A further advantage of the theory that metabolic products of adrenaline are responsible for schizophrenia is that it enables us to explain quite simply the role of psychological factors in schizophrenia One may postulate two factors (1) a genetic predisposition which may be stronger in some people than others, and (2) different patterns of emotional experience that, lasting for a sufficient time, may give rise to different patterns of biochemical activity in the vastly complex and variegated anatomical and biochemical mechanisms that underlie the experience, coordination, and expression of emotions, attitudes, dreams, wishes, unconscious desires, &c Some of these patterns may be more susceptible than others to the action of the toxins which produce schizophrenia Some may even produce such toxins or function at a degree of neurohumoral imbalance in the mechanisms sufficient to cause aberrant behaviour typical of schizophrenia One should not underestimate the biochemical and electrical storms that must sweep through the brain in the advent of powerful emotions The extreme range of symptoms and the variety of individual responses to L S D and mescaline again suggest that there are great individual biochemical differences in the higher mental functions

A final advantage of our hypothesis is that there are already well-known metabolic diseases due to abnormalities in the metabolism of tyrosine (adrenaline is a derivative of tyrosine) phenylpyruvic oligophrenia, alkaptonuria, albinism, and tyrosinosis

In view of all this evidence it is safe to conclude that there are now enough facts to show that purely psychogenic theories of the causation of schizophrenia along psychodynamic lines can no longer be held as total explanations of the causation of schizophrenia Their place should be in a presentation of contributory factors, as indeed are the biochemical factors I have been discussing

I am most grateful to Dr Julius Axelrod, Dr Erminio Costa, Dr Aaron Feldstein, Dr Harold E Himwich, Dr Hudson Hoagland, Dr Abram Hoffer, Dr Sten Martens, and Dr Humphrey Osmond for their help and welcome advice

Congress

DIABETES

The third congress of the International Diabetes Federation was held in Dusseldorf from July 21 to 25, under the joint presidency of Prof. J P Hoet (Louvain) and Prof K Oberdisse (Dusseldorf) The congress received a telegram of welcome from Dr Adenauer, and honorary degrees were awarded to Dr E P Joslin and (in his absence) to Prof B A Houssay

In his Banting memorial lecture Prof G Katsch (Greifswald) spoke on Conditions for Conditioned Health He gave a comprehensive review of the social aspects of diabetes and repeated the advice to diabetics which is inscribed on the walls of his own clinic—"courage, moderation, and activity"

The congress sessions were divided into lay and scientific, and usually one lay and two scientific sessions were in progress simultaneously Virtually every aspect of diabetes was discussed, most time being devoted to the oral antidiabetic compounds, largely exploited since the Cambridge congress three years ago, and to various aspects of diabetic angiopathy, which is a problem of growing importance

Action of Insulin

The discussion of the action of insulin left the subject more open than it had been three years previously There is now no agreement about the importance or otherwise of insulin's action on the liver, especially in view of the negative results of Ashmore, Cahill, Earle, and Zottu on the effect of insulin on glucose production by the liver measured directly in experimental animals

Prof C de Duve (Louvain) still believed, however, that insulin affected hepatic gluconeogenesis primarily and not secondarily The evidence for the permeability hypothesis of insulin's action was well stated by Dr R Levine (Chicago) and Dr C R Park (Nashville) Dr Park believed that glucose permeates the cell by an enzymic process, and Dr B L Horecker (Paris) drew some interesting analogies with enzymic blocks of sugar permeases in mutants of *Escherichia coli* Dr P J Randle (Cambridge) suggested that insulin permits glucose to enter the cell by inhibiting the role of energy-rich phosphate bonds in establishing the barrier to glucose on the cell surface Anoxia or salicylates seem to encourage the permeation of glucose by a direct inhibition of oxidative phosphorylation

Dr D B Martin (Boston) described the immediate direct action of insulin on adipose tissue in contrast to the apparently delayed effect of insulin on liver Prof C N H Long (New Haven) indicated that the effects of the adrenal glucocorticoids on the liver were independent of insulin, and referred to steroid diabetes as an overflow diabetes, the excess glucose coming from increased gluconeogenesis in the liver and a partial block of glucose utilisation in the muscles

Insulin Assay

Some of the reasons were discussed for the different serum values obtained by slightly differing techniques based on the isolated rat diaphragm Dr H v d Geld (Amsterdam) considered that small amounts of adrenaline significantly opposed the action of insulin by reducing glucose uptake by the diaphragm, and there was general agreement that higher absolute values of insulin activity were obtained if dilute rather than whole serum was used It was suggested that results of different workers would be more comparable if a 1-in-10 dilution of serum was used, and that the results should be expressed as units of insulin activity per litre of serum

Dr Martin described the advantages of the insulin assay using rat adipose tissue and ^{14}C glucose The sensitivity of the method is similar to that employing rat diaphragm, as described by Dr J Vallance-Owen (London) and Dr P H Wright (London) Insulin activity can be shown to be associated with the serum-proteins, mainly the β-globulins according to the Amsterdam group, or the electrophoretically slow-moving albumin according to Dr K W Taylor and Dr Randle (Cambridge)

Various insulin inhibitors have been recognised in serum These include insulin antibodies in the inter-γ-β-globulin zone, the lipoproteins in alloxan-diabetic rats, and fractions in the serum of depancreatised cats, dependent on intact adrenal and pituitary glands, as were described by Dr R H Williams (Seattle) Dr J B Field (Bethesda) has found an additional insulin antagonist, migrating electrophoretically with the α_1 globulins of patients in diabetic ketosis Dr W Oakley (London) described the dramatic effect of prednisone in reducing insulin resistance in certain types of diabetes, which he has been studying

Diabetic Angiopathy

Dr D Adlersberg (New York) emphasised the ætiological role of raised serum-triglyceride levels, and Prof P A Bastenie (Brussels) drew attention to the high rate of excretion of adrenal 11-oxysteroids in such patients Prof M Burger (Leipzig) considered that insulin lack directly affected the capillaries and thus the blood-pressure and eventually the electrocardiographic findings Dr H T Ricketts (Chicago) hoped to exclude genetic factors by working with dogs with experimental diabetes of long duration The role of poor diabetic control in promoting angiopathy was clear but less important than simple ageing Prof K Lundbaek (Aarhus) described the long-term development of diabetic vascular disease in the human, and suggested that it was the cause of other late complications, such as rubeosis iridis diabetica, diabetic osteopathy, the " stiff hands syndrome ", and multiple areolar exudates of the retina Little helpful information regarding the treatment of angiopathy was forthcoming apart from the desirability of good diabetic control

Discussing diabetic nephropathy, Dr H F Root (Boston) emphasised its increasing importance as a cause of death in early-onset diabetics, but he believed that optimal control could postpone or prevent its development Dr J F Hartmann (Minneapolis), on the other hand, using electron microscopy of renal biopsies, had found evidence of renal involvement as early as five months from the clinical onset of diabetes Dr A Goth (Budapest) produced renal lesions in rats by causing wide variations in the blood-sugar with insulin alternating with glucose by stomach tube Prof P Kimmelstiel (Milwaukee) showed a series of beautiful slides illustrating the diabetic kidney condition named after himself and Prof Clifford Wilson (London) The stages of diabetic retinopathy were also well illustrated by Dr R Thiel (Frankfurt) Dr T Yoshida (Osaka) claimed that calcium pantothenate in association with good diabetic control effectively relieved the symptoms of diabetic neuropathy

Intermediary Metabolism in Diabetes

Dr O Wieland (Munich) drew attention to the probable competition between the metabolites of fat and carbohydrate for the available coenzyme A, which was concerned with acetylation processes Dr I Kelsey Fry (London) had studied the changes in blood-pyruvate levels during glucose and glucose and insulin loads in normal subjects and diabetics Only " brittle " diabetics showed a consistent pattern with high fasting pyruvate levels, unaffected by glucose but increasing sharply after insulin and glucose He suggested that diabetics had a metabolic block at the level of pyruvic-acid-oxidase, and integrated this suggestion with the effect of dimercaprol (BAL) in reducing blood-pyruvate and glucose levels in such diabetics

Diabetes and Pregnancy

Dr A Hagen (Gentofte, Denmark) performed a useful service in establishing the blood-sugar values of normal and prediabetic women during pregnancy Dr J J Hoet described experience in his father's clinic in Louvain, which specialises in the study of prediabetic pathological pregnancies Dr Hoet indicated his faith in the beneficial effect of insulin, even in prediabetic pregnancies, and of thyroid when indicated The infant mortality of diabetic pregnancies can be most effectively reduced by strict diabeic control, as was illustrated by the findings of Dr J M Malins (Birmingham) With improved survival-rates the incidence of congenital anomalies in the babies would assume increasing importance, and Dr R G Paley (Leeds) reported studies on this aspect

Dr M Osler (Copenhagen) measured the total body-water and extracellular water in the newborn infants of normal and of diabetic mothers The infants of diabetic mothers contained significantly less water, presumably because their body contained relatively more fat and glycogen than that of infants of normal mothers Dr R Boulin (Paris) made the interesting point that diabetic mothers have nearly three times the tendency of diabetic fathers to hand down the diabetes to their children

Oral Antidiabetic Drugs

Much of the discussion of the oral antidiabetic compounds centred on the mechanism of the hypoglycæmic action of the sulphonylureas Prof A Loubatières (Montpellier) felt confident that these compounds stimulated the release of insulin and later the hyperplasia of the β cells of the islets of Langerhans, but his work was based on experimental animals, not man Investigators of human diabetes, such as Dr T Munkner (Copenhagen), had shown that tolbutamide reduced the hepatic glucose output without changing the hepatic or limb blood-flow or affecting the arteriovenous blood-sugar difference in the leg Prof J D Achelis (Mannheim-Waldhof) agreed that some of the drug's action in humans is extra-pancreatic Prof C V Holt (Hamburg) attributed the main hypoglycæmic action in man to a stimulation of endogenous insulin secretion, and other investigators brought forward evidence to support this view Thus, Dr E F Pfeiffer (Boston) found a greater increase in the insulin activity of the portal venous blood of animals receiving sulphonylureas than that of the femoral venous blood This raised the question whether insulin in the portal venous circulation had a different effect from insulin in the systemic circulation Dr L L Madison (Dallas) had evidence to support this suggestion Thus in dogs the slow administration of insulin into the portal vein produced as much hypoglycæmia as a peripheral injection, but with much less effect on the arteriovenous blood-sugar differences Moreover, the hepatic binding of ^{131}I-labelled insulin was significantly greater when it was given into the portal vein than when it was injected systemically Prof W J H Butterfield (London) and Dr O J Rafaelson (Aarhus) confirmed that the sulphonylureas increased the uptake of glucose in the muscles of the intact human and of the isolated rat diaphragm respectively This could be explained by an insulin-like action, although it did not constitute a proof Further confirmation was provided by Prof Russell Fraser and his colleagues (London), for they found in a blind trial that tolbutamide would raise the plasma-insulin activity only in those diabetics who responded satisfactorily to the hypoglycæmic action of tolbutamide It would thus appear that the relatively great effect of the hypoglycæmic sulphonylureas on the liver as compared with on the muscles (Dr V Conard, Brussels) might be explicable if endogenous insulin was released and had its main effect on the liver

Many studies were reported of the comparative toxicity and efficacy of carbutamide, tolbutamide, and the new sulphonylurea, chlorpropamide European workers have not found cause to avoid carbutamide as studiously as their American colleagues, who were alarmed by early reports of bone-marrow depression Luckily the serious effects of tolbutamide on the liver of dogs have not been noted in man or indeed in other experimental animals There has been an increasing tendency to use carbutamide only in small doses (Dr R Boulin, Paris) or in intermittent courses (Dr I Murray, Glasgow) The toxicity of tolbutamide was less than that of carbutamide (Dr F Bertram, Hamburg, Dr A Marble, Boston), but neither compound was as potent a hypoglycæmic agent as chlorpropamide, which needed to be given in a dose of only 200–500 mg per day to maintain its effect The long-term toxicity of chlorpropamide has still to be established, but it is already apparent that doses comparable to those used for tolbutamide are certainly toxic (Prof H A Heinson, Zeven, Dr Joan Walker, Leicester)

Much information was also presented about the hypoglycæmic effect and toxicity of another oral antidiabetic compound, phenylethylbiguanide (D B I) and its analogues Such compounds inhibit certain oxidative enzymes (Dr R H WILLIAMS, Seattle) and increase the glucose uptake even of depancreatised animals or of juvenile diabetics Hepatic gluconeogenesis is sharply depressed, and doses of more than 100–200 mg per day produce a high incidence of toxic effects, such as anorexia, nausea, vomiting, diarrhœa, weakness, or a metallic taste in the mouth Dr P WHITE (Boston) has shown that D B I can reduce the insulin requirement of juvenile diabetics and be used alone in a few of them Such synergism between different hypoglycæmic agents was illustrated in a case of insulin-resistant diabetes by Dr N BILHAN (Istanbul), using tolbutamide with insulin, and by the use of salicylates with sulphonylureas by Dr J M STOWERS (Dundee)

A New Insulin

Dr J SCHLICHTKRULL, of the Novo Laboratories, Copenhagen, described a new insulin, which may be an improvement on the lente series No zinc is added to the insulin crystals, and a quicker initial action than that of lente insulin is obtained by including a proportion of pig insulin in a mixture with slower acting beef insulin, prepared in the same way

Detection of Diabetes

The lay sessions of the congress made progress in establishing the need for and methods of diabetes detection drives A committee representing 14 countries was formed and hopes to work in association with the World Health Organisation Dr M NAKAYAMA's detection drive among people over 40 years of age in Tokyo revealed 3·1% of previously unknown diabetics and another 3·3% of suspected diabetics Dr J J A REID (Dundee) discussed the results of his personal survey of employment problems among diabetics, and Mr J G L JACKSON (London) reported on the results of a questionnaire about employment sent to the 22,000 members of the British Diabetic Association The expense of diabetic diets and insulin is still a problem in many parts of the world. Dr W. TROUP (Ottawa) described the increasingly progressive attitude of insurance companies to the life assurance of diabetics

Parliament

Commemoration Day

WHEN the National Health Service was started ten years ago Mr ANEURIN BEVAN was Minister of Health, and on July 30 he appropriately opened the debate held in the House of Commons to mark its tenth anniversary Behind the service, he said, lay two principles—the provision of a comprehensive, free, health service for all the people of the country in time of need, and the redistribution of the national income by a special method of financing the service On the whole he thought that the first principle had been achieved and that there was general, though not uncritical, satisfaction with the therapeutic side of the service

About the financial side he confessed that he was getting a little worried When the service was being planned, he had rejected the method of insurance as inapplicable to a scheme of this kind and had decided that the fairest way to finance the service was from Exchequer funds by general taxation As the Treasury was to carry the full cost of the service, it claimed the portion of the National Health Insurance contribution which had formerly been used for medical benefits This was reasonable enough, but, Mr Bevan stressed, it was an appropriation-in-aid taken from the Insurance Fund by the Treasury, and there was no organic, financial, or administrative link between National Insurance and the National Health Service By assuming this link, the Government, instead of increasing taxation to find additional money for the service, had called for the money from the National Insurance Fund by a poll tax This was an unjustified transfer of the burden from the well-to-do to the poorest

One of the difficulties of the service had been the number of Ministers They had followed one after the other, to their mutual embarrassment and to the dismay of the nation By the time that they had acquired a jealousy for their position and a knowledge of it, they were sent away They had not enough time in office to acquire sufficient stature to be able to stand against the importunities of the Treasury

Mr Bevan had always regarded pay-beds as one of the concessions which had to be made to the pressures of the moment when the service was started He was distressed to learn that this concession was sometimes abused. He would not say for a single moment that the practice of allowing a paying patient to jump the hospital waiting-list was universal, but it had amounted to so grave an abuse as to impair the service

When people talked about the cost of the service he hoped that they would take into account that the service had a secret silent column which never appeared in the balance sheet It comprised the enormous number of people who were back at work and who would not be there without its help

Mr DEREK WALKER-SMITH, the Minister of Health, thought that ten years had been long enough to establish some sound record of performance, but was yet short enough to make it appropriate to concentrate on the future rather than the past Two signposts for future action were, he suggested, provided by our success with tuberculosis and diphtheria It showed the importance and potential of preventive medicine and the possibility of solving the accommodation problem of our hospitals by eliminating some diseases Two of our gravest problems—the care of the aged and of the mentally ill—had a common denominator In both we sought a shift of emphasis to outpatient treatment and care within the community Only in this way could we hope to have a service adequate to the needs of the patients without creating a burden too great for our resources to bear

But whatever success we achieved in this policy, there would always be an important residue of patients who would need care in hospital At present the running cost of hospitals took nearly 54% of our total expenditure on the health service Where so much money was being spent we must seek the highest common factor of efficiency and economy in administration The Ministry's experimental organisation and methods service had already shown that we could best ensure economy by critical and detailed analysis of hospital work on the spot Particularly in manual work large savings of time could sometimes be made, and these potential savings were a hidden reserve which could be used to offset the recent reduction in working hours and to relieve our nurses of extraneous tasks The present experimental O and M unit was to be enlarged and made permanent under a full-time assistant secretary by the Ministry He was also considering a suggestion by the Royal College of Nursing that an advisory council on work study should be set up

The country had made a very considerable investment in health, and he thought that with the years we should see an increasing return The return we needed was not only better treatment and improved prospects of cure, but the prevention and where possible the elimination of disease, resulting in a positive improvement in health which would be reflected "in the factory, the foundry, and the farm, and not merely in the convalescent home"

Dr A. D D BROUGHTON believed that one of the most serious problems of the service was the overcrowding in the mental hospitals, yet he asked the Minister to resist proposals to build new hospitals to relieve congestion. Dr Broughton was sure that wherever possible the patients should remain in familiar surroundings and if possible at work.

Mr ROBERT COOKE thought that the craving for new apparatus should also be resisted. These things quickly went out of date and this could lead to work Clearly the best facilities should be available, but not necessarily in every hospital

Sir FREDERICK MESSER believed that more money should be spent on keeping patients out of hospital He would like to see the executive committee become a more effective administrative unit, with closer liaison between general practitioners and the local health authority, the domiciliary services could usefully be extended One of the inconsistencies of the N H S was that a patient usually had to pay for a home help, yet he was not asked for any contribution towards the wages of the wardmaid Stronger incentives for a more efficient domiciliary service would, in his view, be better for the patient and cheaper for the taxpayer

Mr Kenneth Robinson was disturbed by the steady drift from whole-time to part-time consultants He, too, thought that some part-time consultants were abusing the pay-bed facilities of the hospital But the main thing about consultants was that we had not nearly enough of them In some areas and in some specialties we needed many more All over the country senior registrars and even registrars were doing work which should be done by consultants What was even more disturbing was that the quality of the registrars coming forward was beginning to deteriorate The worry and frustration among registrars had acted as a powerful disincentive to medical graduates to make their way on to the consultants' ladder

Mr Arthur Blenkinsop was dismayed by the calm assumption that we were wasting enormous sums on the service when in fact the total expenditure was by no means so terrifyingly great in real terms People were terrified because for the first time they were seeing the total expenditure on medical care expressed in money Our expenditure per head by the population was no greater than that of other countries, and much less than that of the United States He regretted a lack of leadership in the Ministry and among the professions concerned with the service As a result, a great deal of the time of highly intelligent and well-trained people was spent on all kinds of professional squabbles which would not be necessary if there were a greater sense of what kind of service we were trying to build and what were the main problems we were trying to solve For instance, we did not seem to appreciate the urgency and importance of industrial health It should be the natural job of practitioners working in groups and linked with industry, as at Harlow and Slough Again, the present local-authority services were very haphazard, yet if we were to cope with an ageing population, they should be given priority Yet by introducing the block-grant procedure, the Government would make it much more difficult for the local authorities to expand their health services What, for instance, was the good of decertifying patients if the local authorities were unable to provide residential accommodation for them?

Mr John Cronin, f r c s, said that though the profession had cooperated in the N H S in an able and honourable way, few doctors had any idea of the economics of the service, and none of them by its administrative framework had any incentive towards reasonable economy even in the best interest of the patient He believed that the service would gain from a mild and general economic supervision of doctors, as doctors, by doctors

Dr Edith Summerskill also thought that the Minister should reconsider fundamentals, and suggested that the capitation system was not calculated to improve the quality of the service For some people it only served as an incentive to achieve the maximum list of patients and encouraged acquiescent prescribing Again was it economical for us to have part-time rather than whole-time consultants? The payment of a consultant by sessions might encourage him to keep his outpatient department fully occupied and his beds full

Mr Richard Thompson, parliamentary secretary to the Ministry, agreed that the local-authority community care services should be enlarged The Government had made it clear that they did not consider that the introduction of the general grant would hinder this The local authorities' associations had, however, suggested that it would be preferable that special financial provision should be made for these services and their views were being very carefully considered

Turning to the future he said that our general aim must clearly be to keep those not in actual need of hospital care and treatment out of hospital and in the community for as long as possible Of all our public services the N H S probably depended most on voluntary help for its administration, and we must be grateful to the members of hospital boards and committees for their work in this worthwhile project "It is in this spirit of cooperation and dedication to a great cause that we can face the future with confidence"

Artificial Insemination

The Earl of Feversham has agreed to serve as chairman of the proposed departmental committee on artificial insemination The committee's terms of reference are

> To inquire into the existing practice of human artificial insemination and its legal consequences and to consider whether, taking account of the interests of individuals involved and of society as a whole, any change in the law is necessary or desirable

Royal Assent

Bills which received the Royal Assent before the end of the session included the Medical Act, 1956 (Amendment) Bill and the Children Bill

QUESTION TIME

Charing Cross Hospital

Mr A G F Rippon asked the Minister of Health whether he had reached a decision regarding the future of Charing Cross Hospital —Mr Derek Walker-Smith replied On Feb 9, 1955, the House was informed by the then Minister that the Government's plans for hospital building expected to start in the next few years included a project for the rebuilding of Charing Cross Hospital at Northwick Park, Harrow This proposal has had to be abandoned because further consideration by the University of London and the University Grants Committee caused these bodies to decide that it was not in the best interests of medical education to remove the Charing Cross Hospital Medical School to Northwick Park

The existing Charing Cross Hospital building is outmoded and inadequate for hospital purposes, and it cannot be properly redeveloped on the same site To meet University requirements, the new site must be within reasonable access of all the facilities of the University, including the basic sciences and general student activities, and in August last the responsible hospital authorities were asked to consider the possibility of rebuilding on the site of the existing Fulham Hospital, which is in close proximity to these University facilities and which also requires rebuilding I am glad to say that a large measure of agreement has been reached by the responsible hospital authorities about the practicability of amalgamating Charing Cross Hospital, the West London Hospital, the Fulham Hospital, and the Fulham Maternity Hospital, as a first step towards the ultimate replacement of all of them by a new general teaching hospital at Fulham

I have given close and careful consideration to all the representations made to me, including those made by the committee headed by the Mayor of Fulham, and I am satisfied that the Board of Governors of Charing Cross Hospital, in close cooperation with the South West Metropolitan Regional Hospital Board, will provide a service to the locality which will compare favourably with that which might have been provided by the rebuilding of Fulham Hospital as a non-teaching hospital

I propose, therefore, to make arrangements for the proposed regrouping at the earliest practicable date so that the replanning of the new teaching hospital may proceed without delay The necessary facilities for clinical teaching will be provided at the new hospital, but the question of preclinical facilities is under consideration in consultation with the University and the University Grants Committee

Institute of Criminology

Mr H M Hyde asked the Home Secretary to make a statement on the official proposal for an institute of criminology

Mr R A Butler replied Discussions have been proceeding with university authorities and I am also consulting the University Grants Committee. I have now been informed by the Vice-Chancellor of Cambridge University that, provided the necessary funds can be made available, the university will be glad to consider the establishment of an institute of criminology, whose functions would include both teaching and research, as well as facilities for exchange of views and information with those concerned with the practical administration of the law. The nucleus of the institute would be the existing department of criminal science, but it would be developed on a broader basis and steps would be taken to associate all interested faculties with its management. I have told the Vice-Chancellor that I warmly welcome this proposal and that I am confident that its fulfilment would make an indispensable contribution to the study of the problems of crime and the treatment of offenders.

Family Planning

Mrs LENA JEGER asked the Minister what were the present facilities within the National Health Service for family planning advice and treatment, and why he did not propose to encourage a widening of existing facilities.—Mr WALKER-SMITH replied: The present facilities are for advice and treatment where pregnancy would be detrimental to health. Help is also given in some areas to voluntary associations by making premises available. I do not consider that there is a sufficient case in present circumstances for seeking to widen these facilities.

New Hospitals

Since 1948, under the National Health Service in Great Britain 1 new hospital has been completed, 3 others are in part use, and 8 are under construction.

Public Health

Sickness Benefit

THE biggest influenza epidemic since the National Insurance scheme began brought new claims for sickness benefit in 1957 up to the record figure of 9½ million. According to the report of the Ministry of Pensions and National Insurance for 1957 which has just been published,[1] 5 million claims (twice the average for the season) were received between late August and the end of the year, suggesting that 1 in 8 of the 20 million people insured for sickness benefit may have had influenza. The peak was reached in the first week of October, when 567,000 claims came in—130,000 more than the highest week's figure in the epidemic of 1951. The epidemic is estimated to have cost the National Insurance Fund £10 million.

Medical Staffing of Hospitals

THE Joint Working Party on Medical Staffing of Hospitals has elected Prof. Robert Platt, P.R.C.P., as its chairman.

This working party was appointed by the Minister of Health, the Secretary of State for Scotland, and the Joint Consultants Committee to study, in the light of experience of the hospital service since 1948 and of all other relevant considerations, the principles on which the medical staffing structure in the hospital service should be organised.

The working party is inviting regional hospital boards, professional organisations including organisations of specialists and the associations of hospital authorities, to submit statements of evidence. Any other body or person desiring to submit evidence should notify one of the joint secretaries before the end of October. The joint secretaries are Mr N. C. Rowland of the Ministry of Health and Dr D. P. Stevenson of the British Medical Association.

Medicine and the Law

Duty to Disclose Epilepsy

A PERSON who suffers from epileptic fits is not under any general duty to disclose the fact, but the law recognises that there are circumstances in which he ought to do so.

A few years ago a workman took employment as a painter without informing his employers that he was subject to epileptic fits and had been warned by his doctor not to work at heights. While working on a platform about 20 feet above ground he had a fit, fell to the ground, and was killed. The platform did not conform to statutory regulations and had it been properly protected the man might not have fallen to the ground. The court held that the two parties were equally at fault, with the result that the damages payable to the widow by the employers were reduced by half.[1]

Even more compelling is the duty of an epileptic who is contemplating marriage. Failure to disclose the facts to the intended spouse may later result in the marriage being nullified. A decree of nullity under section 8 of the Matrimonial Causes Act, 1950, has been granted to a woman who married in ignorance of the fact that her husband suffered from epileptic fits.[2] At the time of the wedding the man was 21, the bride 18. The man had the first attack three months before the wedding when discussing the arrangements with her. He did not have hospital treatment as his doctor, who diagnosed an epileptic fit, advised. He had a similar attack on the occasion of the wedding ceremony before the bride had got to the church; she was not informed of it although the ceremony was late.

Although the man had lodged at the home of the girl's parents before the wedding, the judge was satisfied that she was entirely ignorant of his condition until after she left him.

Section 8 of the Matrimonial Causes Act, 1950, provides that recurrent attacks of epilepsy are sufficient ground for a decree of nullity provided three conditions are satisfied. The petitioner must be ignorant of the fact at the time of the marriage, proceedings must be instituted within a year of the marriage, and marital intercourse must not have taken place with the petitioner's consent after discovery of the fact.

In England Now

A Running Commentary by Peripatetic Correspondents

NOT being an efficient G P —that is, not having a secretary—I'm constantly facing the problem of remembering my patients' names When one enters my surgery I often find myself saying (to myself, of course) "Ah! here comes 193-Copthorne-Avenue, or 61-Huntscliff-Common" Then aloud, diffidently and apologetically—"Er, I'm afraid I've forgotten your name"

Not so with the Brown family I know them all very well Mr Brown, now resting in peace, I saw every month for all the eight years I had been in practice He needed dressings for his eczema Then I saw him almost daily for many many weeks while he was under my care in the local G P hospital and during his final long illness at home Mrs Brown, too, I have greeted many times during my repeated cures of her leg ulcers—the relapses, that is Then there's Mr Brown's sister, who had a very severe ophthalmic herpes, and there's unmarried daughter Joan—I Q not very high and definitely odd The son, Eddie, has 37 attendances recorded during the past eight years, strangely enough without there ever having been noted a firm diagnosis (should it be inadequate personality or perhaps *inadequate family doctor*?) So when a Brown comes into my surgery I don't say to myself, "Ah! here comes 34-Acacia-Drive," I say "Here's Eddie Brown" or "Here's Joan Brown"

But I hadn't seen any of the family for three or four weeks, when a note came through my door "Would you please come to see Mrs Brown She has been at M—— for a few days and has had a stroke She will be home at 5 o'clock" At 5 15 sharp I am at 34, Acacia Drive "Hello, Mrs Brown, what's happened?" I asked "Didn't the doctor at M—— telephone you?" she said "No," I replied, "not yet" "Well," said Mrs Brown, "I expect he's had some difficulty in finding your number None of us could remember your name"

* * *

The heart bleeds for your correspondent of last week beneath whom plastic seats are continually crumbling Such a long tale of disintegration must surely have a cause and he had better take a careful look at his profile in a full-length mirror, or better still ask for the candid comments of his wife who will be more objective There comes a time when the odd stones come on us with a rush 13¹/₂ is easily confused with 14¹/₂, and pretty soon it will be 15¹/₂, but by then the earlier figures have been forgotten and one goes about in the fond fiction that it was 15¹/₂ all along This is known as "repression of an intolerable memory" (Freud) and operates also on paunches, chins, bags under the eyes, and receding hair one cannot recall the time when these things weren't It also explains why old photograph albums get so easily misplaced

Insight comes slowly, and it is always easier to spot increasing disproportion in others realisation came ultimately to me, not through shattered seats, but tennis My service matured with increasing years and gained in power and reliability, as did my ground strokes middle-aged guile enhanced my skill and things were pretty good until I attempted the overhead smash Lobs which I used to "jump to" and catch squarely in the middle of the racket started to get lost in the short strings at the end, and this year hit the wood Next year I shall miss altogether It could be argued that people are lobbing higher these days, but I *know* It is all a question of power/weight ratio

* * *

I had no particular reason to question the mode of arrival and departure of the night sisters until one night after a party, when I happened to be on duty late, I came across a door which I had not noticed before I opened it and peeped in The room was bare except for a line of hooks on which hung in a neat row seven long cloaks, six were a dark green, the seventh was jet black On each cloak rested a high-pointed black cap, beside each cloak, propped against the wall, was a tall broom, on the ground beside each broom a huge black cat snoozed This sight aroused my suspicions

The next morning before dawn I hid myself near the front door hoping either to confirm or disprove my suspicions I hardly dared to breathe as the first sister appeared at the end of the corridor, came nearer, and walked past me She had changed out of uniform, wore a heavy overcoat, and carried a large bag I wondered what was in the bag She reached the front door, stood still for a second gazing about her, as though sensing that all was not quite as usual, opened the door and walked off down the drive Each sister left in turn, and last of all the night superintendent, whose bag was a size larger than the others, came into sight, and stood by the front door for a second before leaving I craned desperately from my hiding-place, and caught a glimpse of some jet-black cloth protruding from her bag This last effort, however, proved my undoing I fell forwards on my face in the middle of the corridor The night superintendent looked back "Good morning, doctor," she said I thought she said it rather spitefully I felt a little chastened, as she too departed down the drive

I suppose it is not for mortal eyes to see *exactly* how the night sisters come and go

* * *

Mrs X-Y was reluctant to send her baby to hospital However, I told her that her baby would be nursed by a specially picked staff in a special ward in a very good hospital and she gave her consent—influenced, I think, by the fact that I had had two babies myself

A few days later I went to the children's ward to see the baby and found her in the arms of a nurse who was trying to get her to sleep Apart from being very cross, my patient was doing well Sister was off duty, so the nurse and I walked up and down the ward for a time and I thought the baby was going to settle down But we happened to stop at the window and we discovered two buxom young women digging the hospital garden, and that seemed to make the baby crosser than ever The young lady gardeners were making a poor job of it and I was tempted to take the baby myself and send the nurse down to give them a hand He was a tough, muscular young fellow and would have finished the plot for them in no time, but I thought the head gardener might not like it So I left him rocking the baby, first on one arm and then on the other, and went on to report to Mrs X-Y I told her that it would have been difficult to find a better nurse

At lunch, the physicist was being sarcastic over clinicians using apparatus which they did not understand The only surgeon present rose at once to this bait and said that he would never dream of using anything which he did not thoroughly understand "Do you use diathermy?" asked the physicist "Of course," was the reply "Very well then, I will bet you sixpence that you cannot answer two out of four *elementary questions about it*" The surgeon looked rather shaken by this but had to agree These were the questions

(1) What type of current is used—e g, A C, D C, or interrupted? What is the approximate voltage and amperage?

(2) What happens when you switch over from "cutting" to "coagulating"?

(3) In what concentration of saline should the pad enclosing the indifferent electrode be soaked?

(4) How can a patient get burnt in areas remote from both the active and the indifferent electrode?

The surgeon's score was   no, my gallstone still bothers me and I think that he already suspects me of being a peripat

Letters to the Editor

REAPPEARANCE OF TABOPARESIS?

SIR,—Some senior and experienced psychiatrists have recently had cause to give considerable thought to the topic of taboparesis One British psychiatrist recently found that there was concern in responsible circles in America on the same topic. When the time-lag between primary infection with syphilis and the onset of taboparesis is considered, it appears possible that the recent virtual disappearance of taboparesis is due to the efficiency of arsenical treatment in the years before the large-scale employment of antibiotics

It may be that cases treated in the early years of the antibiotic era have yet to develop taboparesis The time factor suggests that the next few years may be particularly important in this respect Recently, a senior psychiatrist with considerable experience of neurosyphilis had four cases referred to him within a very short period—more cases than he had seen for a very long time previously Two of these cases could easily have been missed by a more junior man with little practical experience of taboparesis Moreover, some of the old characteristic physical signs seem to be changing somewhat

It may be hoped that fears of a reappearance of taboparesis on a considerable scale may prove groundless, but there appears to be reason for clinicians to be very alert on this topic, so that if an increase in the number of cases should occur, the sufferers from it may be diagnosed early and, therefore, successfully treated

CHILDREN IN HOSPITAL

SIR,—In a lecture given to the Central Council for Health Education, Professor Illingworth (July 26) has made some extraordinary statements about infectious-diseases hospitals Many of these provocative remarks were refuted at the conference but apparently with little effect on the subsequent publication of the lecture by the Council and by your journal

Professor Illingworth's personal experience of infectious-diseases hospitals would seem, from his lecture, to be limited to the pre-war era Only this can explain his recommendation that the great majority of cases of uncomplicated measles and scarlet fever should be nursed at home Of course, this has been the common practice for many years and certainly these cases are only rarely admitted to the infectious-diseases units in the London area

All would agree with his comment that children should not be admitted to infectious-diseases hospitals unless it is really necessary, a recommendation which would apply to children entering any hospital It is difficult to see, however, what advantage would be gained in establishing isolation units at each general and children's hospital except in sparsely populated areas The Royal College of Physicians view, that in every pædiatric unit isolation accommodation is essential, is a wise one, considering the frequency with which such units go into quarantine with chickenpox and measles, but to convert existing general and children's hospitals, so that infectious cases can be admitted as routine policy, would merely duplicate facilities already in existence. The arrogant assumption that only a pædiatrician is capable of looking after cases of gastroenteritis is shown in its true light when one considers the large number of such cases which have been efficiently treated by the medical and nursing staff of infectious-diseases units over many years Can it be that the pædiatric world, tiring of enuresis and metabolic rarities, is looking for fresh pastures?

The Professor's wildest assertion, "that a high proportion of children admitted to infectious-diseases hospitals are not suffering from an infectious disease at all", can only mean that he equates infectious disease with notifiable infectious disease, two entirely different matters Admittedly some forms of pneumonia and meningitis are not infectious, but the majority, including many of the viral and bacterial varieties, are most certainly so Can the infectivity of these conditions be determined at the time of admission? If it could, we would not be faced with the tragedy of paralytic poliomyelitis developing in a child admitted to a general children's ward for treatment of some other condition—an event not unknown in the experience of most physicians dealing with infectious diseases Yet the polio virus has low infectivity in comparison with the Echo virus, to mention only one No, Sir, cases of pneumonia and meningitis, in common with other infectious diseases, should continue to be admitted to isolation units for investigation and treatment, for only there can the interests of the individual and the safety of the community be reconciled

Coppetts Wood Hospital,
London, N 10

R T D EMOND
Physician-Superintendent.

SIR,—Professor Illingworth's lecture to the Central Council for Health Education contains some provocative assertions regarding infectious-disease hospitals His statement that "the great majority of cases of uncomplicated measles and scarlet fever should be nursed at home" comes about twenty years out of date and belongs not only to a pre-antibiotic era but to a pre-war era This has been the practice in Greater London, if not over most of the country, and has contributed to the great reduction in the number of available infectious-disease beds per thousand of the population over the past twenty years

Professor Illingworth states "The aim of cubicles is the prevention of cross-infection, and we all know how regrettably they fail to achieve this" Cross-infection is most likely to occur in *Escherichia coli* infective gastroenteritis and salmonella infections in infants Apart from these incidents cross-infection is no problem in infectious-disease hospitals where the cubicles are well planned and where the prevention of the spread of infection is instilled into all staff trained in these hospitals or units

His inaccurate assertion that only a pædiatrician has experience of infectious diseases requiring specialised treatment (e g, gastroenteritis) is quite out of place, bearing in mind the amount of good work that has been done throughout the years in infectious-disease hospitals Gastroenteritis, which he quotes, and of which we saw so much in the past, has now ceased to be the problem it was in this country

Could it be that, with the tremendous improvement in nutrition and in child health generally—partly contributed to by the public and school health services and education of parents, and partly by the advent of the antibiotic era—the pædiatric fraternity is looking for further spheres of activity, in which other people have worked when problems were greater than at present?

IDIOPATHIC THROMBOCYTOPENIC PURPURA AND DISSEMINATED LUPUS ERYTHEMATOSUS

SIR,—We were interested to read an annotation on the treatment of idiopathic thrombocytopenic purpura (I T P) in the *British Medical Journal* of July 20 which deals largely with two papers published by Dameshek and his colleagues[1,2] These authors claim that approximately 25% of all patients with apparently typical I T P in whom the spleen has been removed will eventually develop disseminated lupus erythematosus (D L E) This is contrary to our own experience, which is given in our paper in *The Lancet* of Aug 2 In none of the 42 cases of I T P submitted to splenectomy, and followed up for periods of from 1 to 29 years, did the clinical features of D L E develop This is also our experience in a large series of splenectomies carried out on patients with portal hypertension and hæmolytic anæmia We therefore consulted the two papers by Dameshek and his colleagues, and we find that, although the figure of 25% is given by these authors, they supply no details of the cases and no supporting evidence that splenectomy either caused D L E or hastened its onset

In the second paper an account of only 1 patient with "idiopathic" thrombocytopenic purpura is given A study of this case-record makes it clear that the patient had stiffness, limited movement, and spindling of the finger joints, and fever, coincidental with the onset of the thrombocytopenic purpura Accordingly it seems to us likely that a collagen disease was already in being This is admitted by the authors who state that " the possibility of a more fundamental disease such as D L E was considered" Whether the severe manifestations of D L E which developed 4 months after splenectomy were the result of the operation or were due to a spontaneous progression of the disease, can only be a matter of conjecture

Lastly, we agree with Dameshek and his colleagues that steroid therapy should be the first line of treatment both in acute and chronic I T P We do not agree, however, that splenectomy is potentially dangerous or of little therapeutic value, since none of our cases developed D L E, while 75% of our "short history" cases of I T P and 50% of our "long history" cases have remained well for periods which in some cases extend over 12 years

A I S MACPHERSON

ASPIRIN AND PEPTIC ULCER

SIR,—The possibility that aspirin may cause hæmorrhage is a matter of considerable importance to patients who have a chronic peptic ulcer, or the diathesis for acute gastric ulceration It is therefore unfortunate that Dr Allibone and Dr Flint (July 26) should "conclude that aspirin, although a gastric irritant, is a rare cause of hæmatemesis" when their data do not warrant such a conclusion Aspirin has been used so extensively and for so long that it cannot come as a surprise that 59 of their 129 controls took the drug, within two weeks of admission to hospital, without ill effect On the other hand, who can say how many of the 61 "series" patients who had taken aspirin precipitated their hæmorrhage (or perforation) by so doing? It is presumably among the ulcer group alone that the risk exists, and therefore a controlled investigation of this problem should be confined to such patients

Department of Social Medicine,
Trinity College, Dublin

ROY M ACHESON

ULCERATIVE COLITIS

SIR,—In psychosomatic disorders there is to date a woeful lack of adequate research, and accordingly even the most tentative hypotheses have too readily gained the status of inviolable laws Dr Sim and Mr Brooke (July 19) are, therefore, to be congratulated on their attempt to test current psychosomatic hypotheses with respect to ulcerative colitis

Some methodological questions, however, arise For instance, do the members of the Ileostomy Association represent a fair cross-section of the ulcerative-colitis population? Further, the questionnaire method—as compared, for example, with the standard interview—may involve significant limitations The reader would have been further enlightened if the items of the questionnaire had been described in detail

Above all, a retrospective survey of the order of appearance of the symptoms of ulcerative colitis (which often arose many years previously) is, as the authors themselves concede, open to error Not only is heavy reliance thus placed upon the patients' memories but a distortion factor may be introduced if conflict-producing situations and emotional disturbance become subject after many years to repression and dissociation That this is liable to happen is indicated by Bastiaans and Groen,[1] who comment thus upon their study of psychological factors in ulcerative colitis patients "Usually the occurrence of such an event [i e, an acute emotional trauma within 48 hours before the illness began] was denied when the patients were asked outright, during the first interview, if anything had upset them When, however, they were given an opportunity to give their life history and encouraged to talk freely about their present situation they told of such events"

Dr Sim and Mr Brooke may have cast grave doubt upon certain hypotheses regarding ulcerative colitis, but this should not be mistaken for the death-knell of a psychosomatic approach to this disease Only long-term longitudinal studies of a prospective nature as well as careful experimental investigations, rather than cross-sectional studies, will permit a sober appraisal of possible emotional factors in this puzzling disease

Southern General Hospital,
Glasgow

A BALFOUR SCLARE

SIR,—Dr Sim and Mr Brooke (July 19) make a big sweep with a small broom when they conclude that the absence of diarrhœa as an initial symptom of ulcerative colitis leaves "little evidence to support existing psychosomatic hypotheses of the origin of the disease" For only in very specious and theoretical misapplication of Freudian theory can anyone so far turn their backs upon the disease in search of its causation

Respectable psychosomatic theories of ulcerative colitis must be based upon the known responses of the colon to emotion or the association of abnormal emotional constitution with the disease

The disturbances of colonic function most clearly induced by emotion have been (*a*) vascular and secretory changes in the mucosa, first described in dogs,[2] but repeatedly observed in man[3,4], and (*b*) changes in the tone and contractility of the colonic musculature Colonic spasm has been shown to be capable of producing rapid ulceration of the colonic mucosa in dogs[5]

The more durable of existing psychosomatic hypotheses are

based upon well-observed facts In addition to emotionally induced changes in mucosa and muscle these include the many studies in emotional and personality types found in ulcerative colitis, from the pioneer clinical observations of Hurst [6] through the character studies of the thirties to the, in some cases, more detailed work of the past decade or so A few other studies not mentioned by Dr Sim and Mr Brooke are listed below [7-9]

The presence or absence of diarrhœa as an initial symptom does nothing whatever to detract from these many deep and massive studies of the psychogenesis of ulcerative colitis To all who have studied it carefully from both aspects this disease is so strikingly based upon a complex of body-mind relationship that it is distressing to find two modern writers who are willing to think such a frail criterion as the time of arrival of liquid stools can leave us "little evidence" of the deeply distorted characters and the profound physical and mental susceptibilities and sensitivities that are causally connected with the symptoms in sufferers from this disease

"EXPERIENCE AND INCENTIVE" AWARDS?

SIR,—The principle of differential payments to general practitioners for the *quality* as distinct from the *quantity* of their work appears at last to be receiving serious attention The stumbling-block of "merit" awards lies in the difficulty of finding a method to assess merit I do not believe that any system which depended primarily on the assessment of the merit of one practitioner by another practitioner could possibly succeed The idea that a board of consultants might do it would surely be as embarrassing to the consultants as it would be to the general practitioner

May I suggest therefore that the word "merit" be dropped altogether and that an alternative "experience and incentive" award be considered?

The difference in such an award is that it would not be beyond the reach of all G P s at some time in their careers For this reason I believe it would be more generally acceptable If payment for it was met out of some fund other than the central pool it could play a big part in what should be its *main* purpose—i e, the promotion of good general practice

For such an award only criteria that are fairly easily assessed could be used I would suggest

(1) 10 years' experience as a principal.
(2) A high standard of surgery premises and equipment.
(3) A list of patients not below a certain minimum, nor yet above a certain maximum considered locally suitable

To those critics of such yardsticks (e g, Burdon [10]) I would point out that while experience is no guarantee of merit, it is fair to assume that every doctor is a better doctor for 10 years' experience (indeed general practice is about the only branch of medicine in which experience is not rewarded)

Again, whatever his capacity, any doctor can surely give a better service to 2500 patients than he can to 3500 Moreover, an incentive to reduce his list would encourage him to take in a partner, or form a group practice Similarly, good premises and equipment, though no guarantee of good work, are essential tools for the job

A fourth element, to form the incentive side to such an award, is more difficult to define I suggest that it should amount to an expression of willingness on the part of the individual to maintain his efficiency This would take different forms Some like to take refresher courses Others prefer to engage in research or to be clinical assistants at nearby hospitals—or to engage in some other form of postgraduate training The essential thing I suggest is that, to qualify for such an award, the doctor would have to bring evidence of his efforts to improve his efficiency in one way or another I see no harm in the idea that such evidence should be produced again, say, every seven years—so that the grass shall not grow, &c

Stratford-on-Avon

CARDS FOR PATIENTS TAKING STEROIDS

SIR,—It is recognised that sudden withdrawal of steroids in patients undergoing long-term treatment may be dangerous, particularly when such patients have been subjected to sudden stress, such as an acute illness, accident, or emergency operation In these circumstances it may be of vital importance for the physician or surgeon responsible for the patient's immediate care to be made aware that the patient has been on steroid therapy, the form in which it is being administered, and the daily dose

The education subcommittee of the Empire Rheumatism Council gave this matter consideration at a recent meeting and reached the conclusion that a useful purpose would be served by the issue of a card to patients receiving steroids, stating the preparation in use and its daily dose The hospital or clinic supervising the patient's treatment and the name and telephone number of the family doctor should also be recorded along with simple instructions to the patient.

I have been instructed by my committee to bring this matter to your notice, as the Empire Rheumatism Council would be prepared to make a supply of these cards available to any physician who might wish to use them

VENTRICULAR SEPTAL DEFECT

SIR,—Your leading article of July 12 favours a classification based primarily on catheter studies and necropsy Open heart surgery enables one to obtain a more physiological appreciation of the anatomical defects, 36 ventricular septal defects have been repaired in the past year at this hospital and as a result it is suggested that the presence or absence of an infundibular pulmonary stenosis plays a major part in the pathological physiology of ventricular septal defects, and that therefore this factor should be included in such a classification

Full cardiac catheterisation figures and operative details are available on 22 of these 36 cases They suggest that the following classification be used

(1) The pulmonary-artery pressure, right ventricular pressure, and systemic pressure are of a similar level These cases have no obstruction to a shunt of blood from the left ventricle to the right ventricle, and they have no obstruction to the outflow tract of the right ventricle

The cardiac catheter passes with ease into the pulmonary artery At surgical repair, though there may be some work hypertrophy of the infundibular muscle, the outflow tract is adequate and no resection of muscle is required

We have had 12 such cases, with 4 deaths

(2) The pulmonary-artery pressure is low, the right ventricular pressure high, approximating to the left ventricular pressure No cyanosis is present

These cases are frequently referred to as an "acyanotic tetralogy of Fallot" The cardiac catheter may pass with some difficulty into the infundibular chamber and at surgery the physiological barrier of muscle which protects the lungs from the raised ventricular pressure may be seen. Resection of this infundibular stenosis is a requisite part of the operation, coupled with repair of the ventricular defect

[7] Moscheowitz E *Amer J med Sci* 1943, 206, 576
[8] Murray, C. D *ibid* 1930, 180, 239
[9] West, R *Lancet* 1946, ii, 899
[10] Burdon, J F *Brit med J* 1958, ii, Suppl. p 27

6 cases with 3 operative deaths

(3) The pulmonary-artery pressure is low and the right ventricular pressure is low The systemic pressure is normal

These are the small muscular defects of the maladie-de-Roger type We have had 4 cases, no deaths

The inclusion of the second group of cases, the "acyanotic tetralogy of Fallot", under the heading of ventricular septal defect is warranted by the fact that group I and group II merge into one another They are both amenable to surgical treatment This differentiates them from the advanced cases of Fallot's tetralogy where the pulmonary artery is of small size and which, even after repair of a ventricular defect and removal of any right outflow-tract obstruction, may well be unable to take the increased flow of blood

NO MORE NEOLOGISMS ?

SIR,—We are grateful to you for your defence of necessary neologisms Indeed, we find Sir George Pickering's criticisms (July 26) of the use of "hæmorheology" a little difficult to follow

It is, of course, true that many great men have studied the flow of blood and the mechanical properties of blood-vessels before a special term for this field of work was needed But surely many doctors must have tried to find causes and cures for diarrhœa and amenorrhœa long before the Greek root "rheo" was so happily introduced to describe these conditions Moreover, Sir George, although quoting our definition for hæmorheology, appears to restrict this term to "the blood-flow in relation to the vessel wall", thus overlooking the fact that much more than this is implied

Rheology, the science of the deformation and flow of matter, forms a part of the official title of scientific societies in many countries The Third International Congress on Rheology will be held in Germany in two months' time The name of this branch of physics is almost identical in all four of the official languages of that congress—English, French, German, and Russian—and, of course, in many other languages Few people can fail to know the meaning of the root "hæmo" The combination of these two Greek roots seems to be indicated if we are to be saved the nuisance of continually repeating the full definition of this branch of science

We, as hæmatologist and rheologist respectively, therefore, move that the term "hæmorheology" be accepted as a very necessary neologism

University of Reading

G W SCOTT BLAIR

SIR,—Sir George Pickering and Dr Pappworth (July 26) raise the question of an ever-expanding, often grammatically objectionable, medical terminology I would emphasise that these two aspects—the tendency of new terms to increase with time, and the suitability of the new word—must be kept distinct in our minds, especially when we reach the point of protest

The first reflects, surely, an inherent characteristic of (scientific) development in general Discoveries in all fields of medicine bring with them new names and we *have* to welcome them! But also, and this is of at least equal importance, the reappraisal of a difficult problem may be a perfectly good reason for a new word, which, when coined, helps to focus and integrate the new notion

Just as the new terms come into use the old ones go into disuse and the survival of a new term depends entirely on the mood, tastes, and existing needs of the people for whom it was intended Beneath this normal mechanism of word production, however, there seem to act, especially during the last few decades, gross exaggerative undercurrents due, I suspect, to three main reasons

(*a*) Specialisation tends to take the form of a closed cult and all new members have to go through a period of initiation in which the apocryphal words of the cult must be mastered, clearly, such words have a high magical value (for they signify the concentrated wisdom of the "specialty"), become irresistible in their perpetual use, dominate the predisposed members of the cult, and, in moments of mystical ecstasy, may lead to new products—Greco-Latin hybrids, or even full blown neologisms should the right mutation take place

(*b*) Words which are quite unknown, or at least difficult to understand with certainty,–foreign phrases and proverbs, Latin-Greek-French-German-or-Oriental-medical-terms, and their hyphenated permutations, have such an appeal that their use in a medical paper appears to strengthen its importance, repel criticism and, perhaps, make its publication a little more probable In this respect also, some writers seem to aspire to associate their names with the introduction of a linguistic novelty, thence the abundance of terms like cephalalgia rather than headache

(*c*) A neologism perpetrated in Greek, Latin, Greco-Latin, &c , is permissible if not advisable, a neologism in one's own language—a strangely difficult thing—is usually considered as an ominous sign of a very serious mental disease

I have not drawn any semantic boundaries around the words jargon, neologism, neology, term, nomenclature, or even barbarism I expect Professor Pickering might enlarge upon this in his promised communication on the matter, such a semantic tidying up will put things in their right perspective and, I hope, might substantiate my foregoing views about the natural production of scientific words and the unnatural exaggeration of the present day towards jargon (i e , towards terms known only to members of a certain group)

Another point that may well emerge from such a study is that when medicine stopped being written in Latin, a conscious effort was made by the doctors of many countries to introduce in their scientific languages terms of Greek or Latin origin with the view to continuing a sense of international understanding in the writings of medical men Such terms (e g , catagma) still appear in medical dictionaries but are completely out of use and should not be confused with the tendency to create jargons—a much more complex phenomenon

Turning to the "suitability" of the new word, *it is here* that the most striking monstrosities are perpetrated against clarity, elementary etymology, and euphony The first two are, of course, more important and mistakes in them are invariably due to ignorance of the *materials employed* To take the example Professor Pickering wants (so very understandably) to challenge, Dr Copley having studied the properties of blood-flow and factors affecting it, felt the need for a comprehensive and precise term for this subject, thus, "hæmorheology" was coined, clearly of Greek material The word the Greeks have for "the flow", however, is not—*rheo* (‘ρεω = I flow) but ‘ροη, which should of necessity be transliterated as "rhoe" This probably appears much like roe and perhaps unsavoury for the occasion

I want to emphasise that this type of offence of being obscure and linguistically inaccurate is almost lost in the wave of the much more serious offence of substantial error natriuresis, (which Professor Pickering quotes) simply means "excretion of sodium" and not "increased excretion of sodium" which the author wanted to say "Kaluresis" is doubly wrong for, at least, it should read "kaliuresis" if not "hyperkaliuresis" which is the accurate, although not welcome, term

From Dr Pappworth's interesting anthology, about 52% of the first list are legitimate, though perhaps not generally used terms, the words neurosophical, dysraphicus, undervascularised, transfusionist, and thoracologist are just clumsy and/or obscure while allergology and ataralgesia are linguistically wrong (they "mean" allergiology and ataraxalgesia)

I do not think I can agree with Dr Pappworth's views on the suffix -itis "Inflammation" is quite accurately translated from Greek in which *φλέγμα* means flame, heat, in inflammation, therefore, redness and swelling usually follow (Hence *φλεγμαινειν* also means "to fester") The looseness of the suffix -osis or -pathy is, I feel, well in line with our increasing knowledge of the conditions to which they are attached

Few would disagree with your view that Natural Selection is a decisive factor in the fate of neologisms But how about jargon? There is much more there than the venturing of an epithet or the display of simple affectation Not only it reflects psychological reactions (some of which I half-humorously mentioned before) but it possesses some of the dubious virtue of scientific "shorthand," at a moment when science is getting more and more longhanded Professor Pickering and all academic teachers can fight jargon mostly by their own example, expressing their views simply and understandably, so that clarity replace undesirable jargon in all medical branches

The Maudsley Hospital,
London, S E5

G M JACOBIDES

SIR,—As an addendum to my letter of July 26 I should like to include the following words, taken from *The Lancet* during 1958

Typology
nomothetic
electroplexy
renoprival
natriuresis
chloruretic
hepatocerebral
immunoconglutinin
reticulohistiocytosis
proteinosis

Immunoconglutinin and reticulohistiocytosis represent two of the ugliest polysyllabic artificial neologisms ever perpetrated

Natriuresis and chloruretic are two of the words singled out by Sir George Pickering (July 26), and renoprival suggests that renal specialists are amongst the worst offenders A *Lancet* article of 1957 contained the word nephritogenic, which apparently has nothing to do with the creation of kidneys but describes those organisms which cause renal lesions, and *The Lancet* (1952) used the term *tubulorrhexis*

Hiding behind the cloak of somebody else's authorship by putting quotation marks around a word is rarely justifiable, because it often merely perpetuates the use of a bad term Examples of this were the use of the word proteinaceous in that article which discussed proteinosis, and a *Lancet* article of 1953 which contained the word metabolician and another of 1955 mentioned dolichostenomelia and phenocopy, all in quotation marks

In 1954 an author repeatedly used sideropenic where most of us would have used the accepted phrase, iron deficiency And in a more recent article[1] the word clubbing, which was used in the title, was later replaced by acropachy Several questions occur to me

(1) What is the difference between acropachy and pachyairia, another term which I have come across in my reading?

(2) Is acropachy synonymous with clubbing, and, if not, what are the other causes of it?

(3) Does acropachy describe only part of the clubbing phenomenon? If so, what is the purpose in giving the components of clubbing different names?

Another problem which confronts the medical reader is the replacement of well-accepted and known names by new terms which the author thinks more accurate For example the replacement of the term fibrocystic disease of the pancreas by either mucoviscidosis or mucoid dysporia. Some authors, wishing to point out the well-known facts that periarteritis nodosa (first named by Kussmaul and Meir as long ago as 1866) is probably neither inflammatory nor necessarily associated with nodules, have coined the following titles for this disease polyvasculitis, allergic granulomatous angiitis, polyarteritis nodosa, necrotising arteriolitis, hypersensitivity angiitis

Most authors would agree that there are clinical gradations between typical angina of effort and coronary thrombosis Does this justify a new term? I would say, "No" If it does, what should it be? I have come across the following answers. status anginosus, severe angina, angina decubitus, infarction without infarction, prodromal coronary artery occlusion, coronary failure, acute coronary insufficiency, intermediate coronary syndrome Perhaps I am wrong in considering all these are one and the same thing

London, W 1

M H PAPPWORTH

SIR,—There is plenty of room for new words in medicine, and we are all indebted to you for your defence of literary freedom The danger of your journal setting out to "uphold the dignity and purity of the English language" by censorship is illustrated by Dr Pappworth's letter of July 26, nearly all of which can be disputed

It is proper that new concepts and classifications should be borne by new words, untarnished by confusion and misuse What is the alternative? Will it please your correspondents if we give new meanings to old words, and will they prefer the confusion if advances in knowledge slip, half digested, into our minds, disguised in familiar forms We are fortunate in medicine that a technical term is unmistakable, and does not, as often in subjects like philosophy and economics, masquerade as an everyday word or phrase Thus, the reader is made aware of his ignorance, and consequent loose thinking is discouraged

Musicians have complained about their lack of technical terms, and its cramping effect A growing subject needs a fluid language, with words passing freely in and out of common use For example, when "hyperchromic anæmias" were redescribed as "macrocytic anæmias" a rational understanding of these diseases became easier

Perhaps one day we may have an *Oxford Medical Dictionary* on historical principles, showing which words are archaic or obsolete, as well as those that are superfluous, misleading, or so ambiguous as to be unusable in precise writing

The real problem is to avoid new words that are unnecessary or ugly If censorship is unacceptable, there is need for a forum where they can be examined, so that Natural Selection can work quickly Such publicity should discourage light-hearted word-making, and also advertise the useful new words, with their associated advances in knowledge It would also in time clarify the indications for new words Perhaps *The Lancet* could find space for an occasional discussion on these lines

For the ugly or ill-chosen words, prevention is easier than reform (although the history of "valvulotomy" shows that reform is possible) The available reference works (Dorland's *Medical Dictionary*, Ffrangcon Roberts' *Medical Terms*, and Jaeger's *Source Book of Biological Names and Terms*) are not widely known, and their users may produce some very clumsy words indeed Euphony is as important as a meticulous classical derivation, and perhaps we should study the practice of drug firms in naming their products, rather than dictionaries of classics and etymology.

There is need for another Gowers to write on *Plain Medical Words*, and show us how to make new ones short and lucid

Glasgow

C MACKENZIE GRANT

---

Obituary

ALFRED ARTHUR EDWARD NEWTH
O B E , M B Lond , D P H

Dr Newth, formerly principal school medical officer for Nottingham, died on July 30 at the age of 70

He was the son of a general practitioner who practised in Haywards Heath, and he was educated at Epsom College and Westminster Hospital After qualifying in 1911 he held house-appointments at the Westminster Hospital, and at hospitals in Wolverhampton and Derby, and in 1914 he was appointed school medical officer to the Nottingham education authority Soon afterwards he joined the R A M C , serving in France, and he did not return to Nottingham till 1918 He remained with the city's school medical service, becoming in due course principal school medical officer, until he retired in 1954 He was appointed O B E in 1952

The care of handicapped children was always his special concern, and in his retirement he showed his practical interest in mental health by becoming a medical officer at the Mapperley Hospital, Nottingham He was a member of the medical advisory committee of the British Council for the Welfare of Spastics He also continued to serve as a valued member of the Ministry of Education's advisory committee Of his long and cordial relationship with the Ministry J E U writes

> " Newth's sound judgment and his exceptional insight into the problems and needs of the handicapped child brought us into frequent consultation and I shall always remember the invaluable help he gave as a witness to the Committee on Maladjusted Children As principal medical officer of Nottingham, he stood at the head of one of the foremost school health services in this country, a service which had been developed by his enterprise and efficiency But his interests covered a much wider field than that of his own county borough He was indefatigable in attending meetings, conferences, and refresher courses, and he did much to inspire his colleagues with his own enthusiasm for the welfare of schoolchildren "

Dr Newth was an able speaker and writer, and the School Health Service Group of the Society of Medical Officers of Health owed much to him as secretary and president Of this work H M C writes

> " Dr Newth was untiring in his endeavours, and his preparation of the papers for the meetings was an indication of his energy and acumen He had an excellent and well-stored brain, and though he was meticulous in details, the memoranda which he prepared for guidance had a lively style So much did his colleagues appreciate his service for the group that a dinner was held in his honour, when a presentation was made to which colleagues from all over the country had contributed.
>
> " His interests were not confined to school health, he played an excellent game of golf and one recalls with pleasure his expert comments on visits to Twickenham He was also a skilled craftsman Despite his knowledge and erudition he was by no means the dull administrator, and his friends will remember his unfailing good humour, tact, and pleasant chuckle "

Mrs Newth is also a member of the medical profession

MALCOLM ARTHUR SMITH
M R C S

Dr Smith, who was an authority on the reptiles and amphibia of Eastern Asia and of the British Isles, died at his home at Ascot on July 24 at the age of 82

He qualified from Charing Cross Hospital in 1898 and shortly afterwards went to Siam For the next twenty-five years he practised in Bangkok where he was medical officer to the British Legation After being attached unofficially to the Court of Siam for some years he was appointed the official court physician In this capacity he saw the celebrated Queen Mother, Queen Saowapa, almost daily He described this part of his life in his book *A Physician at the Court of Siam* (1946)

Throughout his life he was interested in zoology, and particularly in herpetology, and made many field expeditions in the Far East in pursuit of his hobby Over 100 papers on the reptiles and amphibia of the East and later of Great Britain (his book on British reptiles and amphibia is the standard work on the subject) testified to the scope of his knowledge and work Most of his collection of 9000 preserved specimens of amphibians and reptiles he presented to the British Museum of Natural History, where he worked for some thirty years after his return to this country He was for nearly twenty years secretary of the zoological section of the Linnean Society and also the first president of the British Herpetological Society, which was founded in 1947

He married Miss Eryl Glynne in 1921 and had three sons, the eldest of whom is a doctor Two of his sons and his second wife survive him

Sir ARNOLD STOTT

R W B , who was one of Sir Arnold Stott's last house-physicians at Westminster, sent these reminiscences to show " his real stature as a teacher "

> The ward round reached the bed of a patient with spasmodic bronchial asthma and Sir Arnold, having heard the history, asked successively the student, house-physician, registrars, and ward sister " What is in his pillow ?" Nobody knew The next move was dramatic and unforgettable " Sister, your scissors " The pillow was slit open and feathers shaken over the ward round " Feathers " was the only comment—but no-one present could ever forget the ubiquitous role of foreign proteins in allergic disorders On another occasion diarrhœa had been present for some days in a patient having medical treatment for a peptic ulcer The student's history was heard with a slightly impatient air, his examination provoking the response " And what was revealed by digital examination of the rectum ? " Silence followed broken by Sir Arnold, " Sister, a glove " Rectal examination was accompanied by the question " What is a scybalum ? " A further silence, then, incredulously, " You *don't* know ? " A still further silence was broken by a rattling sound as a scybalum was rolled along the wooden floor Crude ? Unnecessary ? Aggressive ?—but then so is disease, and the comfort brought to patients later by those present through awareness of the possible agonies of constipation could be said to justify it
>
> Accurate and economic use of words was another lesson Sir Arnold repeated time and time again " What diet is he having, Dr —— ? "

"A light diet, Sir" Pause, then "Phosphorescent?" Or the cutting interruption when told the fauces are injected "Who injected them?" or when told a patient had a temperature "Everyone has a temperature Do you mean pyrexia?" These remarks were delivered quietly and almost resignedly and never caused personal offence "You have told me the joint is swollen," he said to one student. "Now tell me the degree. Is it slight, moderate, or considerable?"

On one occasion Sir Arnold wrote a prescription putting the wrong date, which was pointed out by sister He turned to the student at his elbow accusingly "You saw me put the wrong date and let me do it." The student replied "Since *you* wrote it how could *I* think it wrong?" Then there was a pause and then "That was a good remark, the first for some time How long have you been on my firm?" At that time a clinical firm consisted of six students and he frowned if anyone tried to tag on "Six is enough for one patient," he once said, "and I haven't enough knowledge for more"

The sad day came when the house job was over It was at the end of tea in Sister's office "I consider you have been a good house-physician," he said, which from him was praise indeed "Slight, moderate, or considerable?" I ventured to inquire "You know the answer to that better than I—but thank you for all your hard work." He smiled, shook hands, and walked away

Lord WEBB-JOHNSON

F R P, who studied medicine at Owens College, Manchester, and at the Middlesex Hospital, writes from Bombay

Lord Webb-Johnson, when he was just Mr Arthur Webb-Johnson, an easy-going jovial young man, was my tutor and guide in surgery Since then, these forty long years and more, we have in a way grown up together, for up to the end of his life we corresponded with each other as colleagues and friends Enough has been said about his good qualities, his professional abilities and public work, but as an Indian, deeply grateful to him for his many kindnesses to a lonely foreign student in his country, I add one more tribute to this great Englishman to whom, along with others such as Sir Victor Bonney, Sir John Bland-Sutton, Sir William Sinclair, and Sir William Fletcher Shaw, I owe all I have achieved in my profession

Appointments

BEGG, ROSEMARY A, M.B Edin., D P H administrative assistant county M O, Kent

BREWERTON, D A, M.D, B Sc McGill, M R C.P, D.Phys Med consultant physician in physical medicine, Westminster Hospital teaching group, London

COLES, H M T, M.D Lond, M.R.C.P, D C.H consultant pædiatrician, Westminster Hospital teaching group, London.

COOPER, C F, M D Lond, M.R.C P part-time consultant physician, Wembley Hospital

HOLLOWAY, J J, M.B, N U I, D P H deputy M O H and deputy principal school M O, Northampton

LLOYD, V A, M B Birm, D P H assistant M O H., Sutton Coldfield area, Warwickshire

THOMPSON, ELEANOR A, M R.C S assistant M O H, north-western area, Warwickshire

Leeds Regional Hospital Board

BENIANS, R G, M.D Cantab, M.R C.P assistant geriatrician (S H M.O), Bradford A and B hospital groups

BIRD, J D, M B Sheff, F F A.R C S, D.A part-time consultant in anæsthetics, Hull and East Riding hospital groups

BURBURY, WINIFRED M., M B Lond, D.P M consultant in child psychiatry, Wakefield and Dewsbury education committees

EASTWOOD, John M B Lond assistant pathologist (S H.M O), Huddersfield hospital group

LEESE, STEPHANIE M., M B, B SC Lond., D.P M part time consultant in child psychiatry, Wakefield and Dewsbury education committees

LITTLE, J C., M.B Brist., M R.C.P E., D P.M consultant in psychiatry, Leeds A and B hospital groups

MATHESON, T S, M B Edin, F R.C.S E consultant in general surgery, Otley hospital group

MOYES, A H, M.B St.And., D P M assistant psychiatrist, Clifton Hospital, York

POLLOCK, A V, M B., B.SC. Cape Town, F.R.C.S consultant in general surgery, Scarborough, Bridlington, Malton, and Whitby hospital group

QUINLAN, A G, M B Lond., F R.C.S. part-time consultant in orthopædic surgery, Scarborough, Bridlington, Malton, and Whitby hospital group

SACKER, L S, M B Lond. consultant in pathology, Hull A and B hospital groups

WILSON, PETER, F R.C.S.E., D O M.S consultant in ophthalmology, Huddersfield hospital group

Notes and News

DISTRICT MENTAL HEALTH SERVICES

EARLIER this year Dr Joshua Carse described in our columns[1] the first ten months' work of the experimental outpatient and domiciliary service which is being offered to mental patients in Worthing The service is based on Graylingwell Hospital, Chichester In a fourth interim report on the scheme he compares the results for the first six months of 1958 with those for the first six months of 1957 (which were also the first six months of the service) The total number of patients has fallen from 721 in 1957 to 657 in 1958 and the number of new patients from 699 to 618 But this reduction is largely among the younger people and the number of patients over sixty-five fell by only 10 Though the care of this group remains one of the problems of the service, Dr Carse is able to report that of the 181 elderly patients referred to the service only 46 were sent into hospital

The success of the service at Worthing, which is 22 miles away, encouraged Graylingwell Hospital to start another district service in Chichester itself at the beginning of this year, and in the first six months 510 patients used the service of whom only 124 were admitted to hospital Together the services at Worthing and Chichester cover three-quarters of Graylingwell Hospital's catchment area, and in the first six months of their joint existence the number of admissions to the hospital was 382 compared with 678 in the first six months of 1956 before the start of the scheme Both at Worthing and at Chichester the services rely heavily on the support of the family doctors who have taken a great interest in the experiment At their request a course of weekly seminars was started in Worthing last May on psychotherapy and the general care of the neurotic patient

University of Cambridge

On June 25 the degree of B CHIR. was conferred on G C Sutton.

University of London

Dr W J H. Butterfield has been appointed to the chair of experimental medicine at Guy's Hospital Medical School

Dr Butterfield, who is 38 years of age, studied medicine at Oxford University and at Johns Hopkins He graduated B.M in 1945 and took the M.R.C.P two years later After holding a junior lectureship in pathology in the University of Bristol, he took up a house-appointment in the Medical Research Council burns unit at the Birmingham Accident Hospital In 1949 he joined the scientific staff of the Medical Research Council He visited the United States in 1950–51 and held a research fellowship at the Medical College of Virginia, to investigate metabolic effects of thermal injury Since his return to this country he has worked at the M R.C clinical research unit at Guy's Hospital His published work includes papers on flashburns and the action of the sulphonylureas in diabetes He was associated with the biological investigations at atomic tests in Australia in 1952 and 1956 and was appointed O B.E in 1953

University of Manchester

The Wellcome Trust has given the university a mobile radiographic and laboratory unit which is to be used by the departments of *rheumatology* and *occupational diseases* for field investigations

Society for the Study of Addiction

At a council meeting of this society, the following honorary officers were elected

President Prof A D Macdonald, *treasurer and secretary* Dr Ellis Stungo, *organiser of meetings* Dr W R Bett

Rockefeller Grants

Recent awards by the Rockefeller Foundation include a grant of $35,000 to a research group at London University studying heredity and genetics in mammals, and a grant of £12,000 to Dr Dorothy Hodgkin of Oxford University for her investigation into the structure of insulin

[1] Carse, J, Panton, N E, Watt, A *Lancet*, 1958, i, 39

Royal College of Physicians of London

At a comitia of the college on July 31, with Dr Robert Platt, the president, in the chair, Dr Saul Adler was admitted to the fellowship of the college (in absentia). The Murchison scholarship for 1958 has been awarded to Dr L G Whitby The following were elected officers for the coming year

Censors J R H Towers, E R Boland, E R Cullinan, J C Hawksley *Treasurer* R R Bomford *Registrar* Sir Harold Boldero *Harveian Librarian* Sir Charles Dodds *Assistant Registrar* J R Ellis *Library Committee* C E Newman, William Brockbank, W S C Copeman, W H McMenemey *Finance Committee* L C Martin, J F Stokes, J W D Bull

The following were elected to the panel of examiners for the membership examination

Terence East, Donald Hunter, Sir Russell Brain, J Forest Smith, L B Cole, J L Livingstone, A C Hampson, Lord Cohen of Birkenhead, A M Cooke, T C Hunt, H K Goadby, F P Lee Lander, W D W Brooks, S J Hartfall, J G Scadding, M L Rosenheim, Horace Joules, Kenneth Robson, Arthur Willcox, Alan Kekwick, Una C Ledingham, J F Stokes, William Phillips, W Melville Arnott

The following lecturers were appointed

Sir Russell Brain (Harveian orator), Alan Kekwick (Bradshaw lecturer), E J Wayne (Lumleian), W S Peart (Goulstonian), P L Mollison (Oliver-Sharpey), Sir Kenneth Clark (Lloyd-Roberts), J F Brock (Humphry Davy Rolleston), all for 1959, D E Denny-Brown (Croonian), K D Keele (Fitzpatrick), F R Bettley (Watson Smith), J W Crofton (Marc Daniels), for 1960

The following, having satisfied the censors' board, were admitted to the membership

Chrystal H Ashton, B M Oxon , G V Balmforth, M B Lond , J L T Birley, B M Oxon , D F Cappell, C B E , M D Glasg , J R Curtis, M B Lond , C T Dollery, M B Birm , E B D Dowdle, M D Cape Town, D W Evans, M B Wales, K F Fairley, M D Melb , O W Hill, M B Cantab , W B Jackson, M B N Z , J V Jones, B M Oxon , N F Jones, M B Cantab , H R Klein, M B W'srand, R E Lovelace, M B Lond , M W McNicol, M B Glasg , Victor Parsons, B M Oxon , Dorab Jehangir Patel, M B Bombay, J S Pennington, M D Melb , R W B Penman, M B Edin , E V Pieris, M B Ceylon, Alan Pollard, M B Cantab , D H H Pullon, M B N Z , A M Rankin, M B Adelaide, M D Readett, M B Birm , J L Reed, M B Cantab , Shelagh M Richards, M B Sheff , Chava E Rotem, M D Lausanne, H H Shawdon, M B Cantab , C K Simpson, M D Lond , J G Sloman, M B Melb , M A Smith, B M Oxon , A E Stevens, M B Lond , D J Stoker, M B Lond , M W Swallow, M B Lond , A K Thould, M B Lond , G E G Williams, M B Cantab , I V Wilson, M B Durh , John Wilson, M B Durh , Susannah M Woodcock, M B Lond , K J Zilkha, M B Lond

Licences to practise were conferred on the following 125 candidates who had passed the final examination of the Conjoint Board

A R Adamson, Richard Allaye, A J R Anderson, A L Ansdell, J T Aroney, J S Bailey, Ekundayo Abayomi Bamgboye, Jehangir Edalji Banatvala, M D Begley, L S Bernstein, W H Bevan-Thomas, G A Bewley, W M Bodger, P R Brass, R C Bretday, P D G Briggs, F H Brindle, M H Brooke, F T Brough, M H Bull, R W Burt, L J Burton, W D Callum, I G Carnegie Brown, I G Christie, P W Clements, D L Common, Daniel Connan, Edith M Cooke, J C Couve de Murville, P A Cullum, T O Dada, Pauline M H Davidson, N A De Heer, Edna M Dunn, A J Earl, R J Earlam, D J Ellam, R C Evans, R J Evans, R E Fallowfield, Martin Fisher, H J L Francis, Paul Fursdon, H A Garfinkel, P B Garland, P M Gelpke, J M Goyder, John Grant, R S Greenwood, J S Grimshaw, A C Halliwell, J D Hardcastle, D C Harvey, A L Hovenden, Anne T Irvine, Anne Jacques, Sadrudin Alibhai Janmohamed, I N L Johnston, Jane M Jones, Winifred N Kaine, N B Kirkland, Hilda Koilpillai, Leslaw Kwasny, Andrea M D Langford, Reza Larizadeh, N K Leiper, D W Lewis, C M Lissaides, P O Liebling, Maxwell Lindsay, Marion R Liss, T A Lloyd-James, A M Lush, D B Macadam, B J T McAvoy, C E Macdonald, J W Mack, K V Mellor, David Mercer, A R Molyneux, Pauline S Monro, H G Morgan, George Moses, I S Muir, Muhammad Yacoub Najjar, A I Nwabueze, N W Oakley, Kolawole Adeniyi Olafimihan, E O Olurin, S B Omi, B A Omi-Okpaku, E H Osborn-Smith, J D Owen, Glenys R Packer, N D Parkin, M G O Parrish, Bruce Pitt-Payne, D Powell, J N Powell, E B Raftery, M J Ramsden, D J Richards, J M R Ridley, Raj Kishore Saksena, Nanjii Sankarayya, M A Sasson, D C L Savage, Montague Segal, R I D Simpson, Margaret R Skelton, B R T Smith, J M Stephenson, J M Taylor, Geraldine Thomas, J B Traherne, W J Trowell, G L Tullett, Fidelis Nwankwo Udeh, A C Upjohn, Sri Krishna-Cumar Rajakesari Villavarayan, Daphne M Ward, P H Waterfield, W F Whimster, Richard Yeo

Diplomas were conferred jointly with the Royal College of Surgeons of England on the following

D A—Kamal Chandra Agarwala, Abdul Amir Alwan Al-Uzri, Bantwal Raghavendra Baliga, F E Bennetts, E P Berwick, F R Bhupalan, Maryrose E Brewerton, Peter Brine, E F Brooks, Georgina D Brown, T H L Bryson, J G Camilleri, W F Carpenter, Gerald Cartmel, Pamela Channon, F B N Clarke, A J Clement, Elmer Clissold, R J H H Colback, C F Conway, Marian H Dadaczynski, J P Davie, I B Denny, G R Dow, Thomas Dowell, A J F Eberle, N L Edmond, H J Ellis, Myrtle Farquharson, E L Fischer, Frank Fisher, Freda W Fleming, J W Gammie, Deb Narayan Ganguly, M A Gilbert, Heath P Gillespie, G B Gillett, J A M Goodwin, B G H Grant, Ajoy Gupta, Marcus Haase, R L Hargrove, Pamela A Harris, Sylvia K Hepton, Eric Holmes, Bridget A Jepson, H W F Jones, Margaret L L Jones, Olive C Jones, Syed Ahmed Kabir, Karingan Ranganath Kamath Norman Kaplan, Shafiquddin Ahmed Khan, P F Knight, R F Knight, J R Lawrance-Owen, M G Leonard, R N Lewis, J G Lindsay, J H L Lloyd-Thomas, J N Lunn, A J McDonald, Hugh McIntyre, T D M McNeill, Frances M McQuitty, S W McVicker, John Mackett, R E Maclaurin, H A Maher, I M J Muir, Ma Shu Poh, Kamil Mustafa, Manohar Laxman Nene, B E Ohmacht, G D Parbrook, Dawood Ahmed Patelle, Audrey M Peeling, P A Pelham, Margaret E Pickering-Pick, W M Pillow, Lora Y Pratt, P B W Price, Denis Proctor, Arnold Rieck, Brenda K Rimmer, R S Ritchie, Pamela D Roberts, Anna I Robertson, Sheila J B Robertson, R H Robinson, David Saltoun, Betty V Scott, R O Selby, H W Stark, J G Thomson, L G von Thomann, Alice van Waterschoodt, H J White, Anne M Wilson, G R V Worrall, P R Wykes, Ming-Hon Yeung, Roman Zeeher

Royal College of Surgeons of England

At a meeting of the council on July 31, with Sir James Paterson Ross, the president, in the chair, Sir Reginald Watson-Jones, Prof D M Douglas, and Mr W A Mill were elected members of the court of examiners

Lieut-Colonel R H Robinson, R A M C , was awarded the Mitchiner medal, Wing-Commander W B Thorburn the Lady Cade medal, and Surgeon Commander W E Crocker, R N , the Gilbert Blane medal

A diploma of fellowship was granted to Padmanabhan Narendran

Diplomas and licences to practise were conferred jointly with the Royal College of Physicians on those named above

Society for Applied Bacteriology

The following officers have been elected

President, Mr D A McKenzie, hon secretary, Mr G Sykes (Boots Pure Drug Co Ltd , Microbiology Division, Standards Department, Nottingham), hon treasurer, Mr G Ellis Jones, editor-in chief, Dr S E Jacobs, editor, Dr C A E Briggs, hon publications manager, Mr A H Walters, hon advertising manager, Mr E J Mann, committee, Dr Eve Billing, Prof E L Crossley, Dr J G Davis, Dr N R Knowles, Dr Jane Meiklejohn, Mr C A Scarlett, and Dr M Woodbine

Isaac Wolfson Foundation

Since this Foundation was started in 1955 it has distributed £1,114,000 Its latest gifts include £250,000 to the Westminster Hospital School of Nursing and £25,000 to the British Council for the Welfare of Spastics to build residences and workshops at Beaconsfield

The policy of the Foundation, which has a capital fund of more than £6 million, is to advance education and health in the United Kingdom and Commonwealth with particular reference to "scientific and technological education, building facilities for higher education, youth activities, general medical research, cancer research, and medical, surgical, and nursing services" The board of trustees includes Sir Stanford Cade and Lord Evans

Surgeon Captain C B Nicholson has been appointed an honorary surgeon to the Queen in succession to Surgeon Rear-Admiral E T S Rudd

The Lancet · Saturday 16 August 1958

CEREBRAL VASCULAR DISEASE IN THE LIGHT OF MODERN TECHNIQUES *

J St C Elkington
M D Cantab , F R C P

PHYSICIAN-IN-CHARGE, NEUROLOGICAL DEPARTMENT, ST THOMAS'S HOSPITAL, LONDON, S E 1, PHYSICIAN, THE NATIONAL HOSPITAL, QUEEN SQUARE, LONDON, W C 1

I PROPOSE now to consider some varieties of intracranial hæmorrhage Extradural and subdural hæmorrhage, though both important and interesting, are self-contained subjects which have not been greatly influenced as regards either diagnosis or treatment by the developments of the past ten years I shall therefore omit them and shall confine my attention to subarachnoid hæmorrhage and to intracerebral hæmatomas

Subarachnoid Hæmorrhage

Since the papers of Fearnsides (1916) and of Symonds (1924), the clinical picture of subarachnoid hæmorrhage and its predominant relationship to the rupture of cerebral aneurysms have been generally recognised

It has become customary to use the term " spontaneous " subarachnoid hæmorrhage to differentiate those cases where the bleeding into the subarachnoid space is the primary event from those in which it is secondary—for example, to head injury or to intracerebral hæmorrhage

The clinical picture of subarachnoid hæmorrhage with its dramatically sudden onset of severe occipitofrontal headache, vomiting, shock, alteration in consciousness, and signs of meningeal irritation are familiar, and I do not propose to dwell on them Occasional atypical cases are encountered where the characteristic bloodstained, xanthochromic fluid is found unexpectedly in a patient with less readily recognisable symptoms or is absent in cases that otherwise seem fairly typical, but by and large the clinical syndrome of spontaneous subarachnoid hæmorrhage is a very characteristic one

Since the original papers already referred to, a number of series of cases have been published with a view to establishing the causative pathology of subarachnoid hæmorrhage Before arteriography was available workers depended for diagnosis either on clinical judgment or on necropsy findings The former introduces many possibilities of error The latter inevitably gives a distorted picture since only the cases with a fatal outcome can be examined Even at necropsy the cause of the bleeding may not be clearly established and it is generally believed that, in the process of rupturing, a small aneurysm or angioma may destroy the evidence of its own existence It should also be remembered that an analysis of the relatively selected cases in a surgical clinic is likely to give results that are not strictly comparable with those obtained from a general hospital where the cases are unselected It is thus difficult to obtain a wholly satisfactory estimate of the relative frequency of the many possible causes of subarachnoid hæmorrhage, but it is noticeable that the more searching the investigation, the greater is the importance attached to the rupture of some pre-existing vascular anomaly of which " berry " aneurysms constitute the great majority and angiomatous malformations a small minority

Table I summarises the findings of a number of authors as to the relative frequency of the common causes of spontaneous subarachnoid hæmorrhage It will be seen that with one exception upwards of 75% of proved cases are attributable to ruptured aneurysms

Until about ten years ago the exact cause of a subarachnoid hæmorrhage may be said to have been largely of academic interest A knowledge of the pathology might enable one to hazard a slightly more accurate prognosis, and it was, of course, important that some curable underlying condition, such as subacute bacterial endocarditis, should not be overlooked The occasions on which one could be certain even on which side of the intracranial cavity the bleeding-point was situated were few, and more precise localisation depended on such associated findings as cranial-nerve palsies, focal fits, or evidence of local damage to the brain—e g , dysphasia, monoplegia, or hemiplegia, which, more often than not, were absent

TABLE I—RELATIVE FREQUENCY OF COMMON CAUSES OF SPONTANEOUS SUBARACHNOID HÆMORRHAGE IN REPORTED SERIES

Author and date	No of cases	Mode of proof	Aneurysms (all kinds) (%)	Other causes (%)	Unknown (%)
Taylor and Whitfield (1936)	43	P M	77	5	18
Magee (1943)	58	P.M.	74	Not specified	
Hamby (1948)	47	P M 41 Op 6	93 6	Not specified	
Hyland (1950)	55	P.M	80	Angioma 3 8	16 2
Wolfe (1953)	62	P M	79	10	11
Walton (1956) (series A)	82	P.M	72 1	15 9	12

P M =postmortem examination Op =operation

In the years from 1925 to 1945 treatment of subarachnoid hæmorrhage could only be conservative and consisted of skilled nursing, the judicious use of sedatives and analgesics, and protracted bed rest The only point in dispute was whether repeated lumbar puncture was advisable or not Under these conditions it was generally recognised that the disorder carried a considerable, indeed a heavy, mortality which increased with age after 40 years It was also recognised that death from the initial hæmorrhage usually occurred within one week of the onset of the hæmorrhage and that the dangers of a fatal recurrence progressively decreased after the first eight weeks But precise and reliable figures were hard to come by as few workers could report on a sufficiently large number of cases under their own care, and pooled results even from the same hospital were open to obvious criticism

Of more recent years a number of series sufficiently large and uniform to be relied upon have been reported

In table II are set out the results of a number of inquiries

TABLE II—MORTALITY IN SPONTANEOUS SUBARACHNOID HÆMORRHAGE

Author and date	No of cases	Mortality (%)	Period over which reckoned
Taylor and Whitfield (1936)	81	63	2 mos
Magee (1943)	150	56	2 mos
Hamby (1948)	130 { 98 in 1st attack 32 in subsequent attacks	51·5	
Hyland (1950)	191	53	6 mos
Ask-Upmark and Ingvar (1950)	138	28 43	" In hospital " Including follow-up
Wolfe (1953)	91	57	" In hospital "
Walton (1956)	312	45	" In hospital "

---

* The second Lumleian lecture for 1958, delivered before the Royal College of Physicians of London on April 17

in the past ten years with regard to the mortality of subarachnoid hæmorrhage treated conservatively It will be seen that, with one exception, they show a mortality-rate of 45–60% and we are forced to the unpleasant conclusion that at an optimistic estimate a patient with a subarachnoid hæmorrhage treated conservatively has only an even chance of being alive two months later I doubt if it is yet generally recognised among physicians how serious is the prognosis in this condition

Although isolated cases had been reported earlier by Dott (1933) and McConnell (1937) and other surgeons, Walter Dandy (1944a and b) was the first to make a serious attempt to eliminate cerebral aneurysms by direct surgical attack

Although in some of his cases the aneurysm had given rise to subarachnoid hæmorrhage, he was primarily interested in the surgical treatment of intracranial aneurysms rather than that of subarachnoid hæmorrhage itself and his cases were selected for operation because the aneurysms could be localised on clinical or radiological grounds and were judged to be amenable to surgical treatment Cerebral angiography was at this stage still in its infancy, and Dandy (1944a and b) referred to it in critical and even in disparaging terms Dandy not only treated saccular aneurysms of the carotid artery by carotid ligation in the neck but also made a direct attack on a number of berry aneurysms situated at the termination of the intracranial portion of the carotid artery and even more distally

In the past ten years cerebral angiography has forged rapidly ahead, and with the development of the percutaneous technique and of improved contrast media it has yielded valuable results over a wide range of cerebral disorders

As regards subarachnoid hæmorrhage it has provided in many cases, for the first time, a means of determining with certainty during life the exact position and nature of the source of hæmorrhage, thus enabling a direct attack on the bleeding-point to be contemplated

Reporting the results in 461 cases of subarachnoid hæmorrhage investigated during the acute stage by bilateral carotid angiography McKissock (1956) and Walsh (1956) give the following figures

Arterial aneurysms	249 (*54%*)
Arteriovenous malformation	53 (*11 5%*)
Primary intracerebral or intracerebellar hæmorrhage	35 (*7 5%*)
No lesion demonstrated	124 (*27%*)
	461

Of the 124 cases in which no lesion was demonstrated by angiography 93 were chosen for follow-up and 31 were discarded because, for one reason or another, bilateral carotid angiography had not been performed on them. Over a period of up to eleven years the mortality in this group of 93 had been 8%, which may be favourably compared with the generally recorded mortality of about 50% during the first two months after the initial hæmorrhage and a further 20% among the survivors as recorded by Hyland (1950) It must surely follow that if the prognosis in cases showing no lesion by angiography is so much better than the average, those cases having a demonstrable lesion must carry a mortality correspondingly higher than the average

The finding of angiomatous malformations as the cause of subarachnoid hæmorrhage in no fewer than 11% of cases (Falconer [1951] had previously found 6%) was in itself an important advance, for the natural history and surgical handling of these abnormalities are totally different from those of leaking aneurysms, and the prospect of permanent cure in cases satisfactorily operated upon is much greater since there is little, if any, liability to recurrence of the bleeding

In a later paper McKissock and Walsh (1956) reporte that the anatomical distribution of the aneurysms demo strated was as follows

Internal carotid artery at level of posterior communicating artery	25%	82 5
Internal carotid artery at level of bifurcation	12%	
Anterior cerebral and anterior communicating arteries	28 5%	
Middle cerebral artery	17%	
Anterior cerebral artery (distal)	3%	
Multiple aneurysms	7 5%	
On vessels in posterior cranial fossa	6%	
Site not established	1%	

These figures, which are generally comparable to thos given by others reporting the results of angiography an also those derived from postmortem studies, make clear that the vast majority of cerebral aneurysms aris from derivatives of the carotid arteries and that they fa into three main groups—(1) those derived from th carotid artery from its point of entry into the subarachnoi space to its termination, (2) those derived from th anterior cerebral or anterior communicating arterie between the hemispheres, and (3) those derived from th middle cerebral arteries in the depth of the Sylvia fissures (fig 7)

While aneurysms in any of these situations may giv rise to subarachnoid hæmorrhage it would be surprisin if structures so diversely placed were to behave identicall after undergoing rupture or proved to be amenable t identical methods of surgical treatment As we shall see the elucidation of these questions has been one of th chief problems to which writers on the subject have paid attention in the past few years

The first series of considerable size of cases of subarachnoid hæmorrhage from ruptured aneurysms treated surgically was published by Falconer (1950, 1951), who reported a furthe series of 50 in 1956 His first series consisted of 50 cases al proved by bilateral angiography to have cerebral aneurysm which had given rise to subarachnoid hæmorrhage All were treated surgically by one or other form of carotid ligation or by direct attack on the aneurysm or by both Falconer reported a survival-rate of 82% with a satisfactory-recovery rate of 66%, and a mortality of only 18%

He pointed out (Falconer 1951) with apparent justification that, as his series contained a considerable number of recurrent cases, the mortality, had they been treated conservatively, would probably have been in excess of 50% He concluded that all cases of subarachnoid hæmorrhage should be investigated as soon as possible by bilateral carotid angiography and that those in which an aneurysm was demonstrated should be operated upon forthwith It might be contended that, from a physician's point of view, it is unnecessary to pursue the argument into greater detail, but the shortcoming of this paper as a guide to management of these cases is that a wide variety of surgical procedures in different combinations were applied to comparatively small groups of lesions which together totalled only 50, and that no clear indication is given as to the interval between the last hæmorrhage and the operation

In his second series of 50 cases, operated on between 1952 and 1955, Falconer's results showed survival-rate 94%, satisfactory-recovery rate 76%, mortality only 6% (Falconer 1956) It is noteworthy, however, that between the two series there had evidently been an important change in policy Whereas in the 1951 series immediate arteriography was advocated in all cases, in 1956 the optimum time for arteriography and surgery was considered to be about the end of the first week after the hæmorrhage This means that the mortality figures of the two series are not strictly comparable, since in that critical week there must have been a considerable number of deaths from the immediate effects of the hæmorrhage, and so the surgically treated cases represented a more selected group from which those carrying the worst natural prognosis had already been eliminated by death

In 1953 Norlen and Barnum published a thoughtful paper

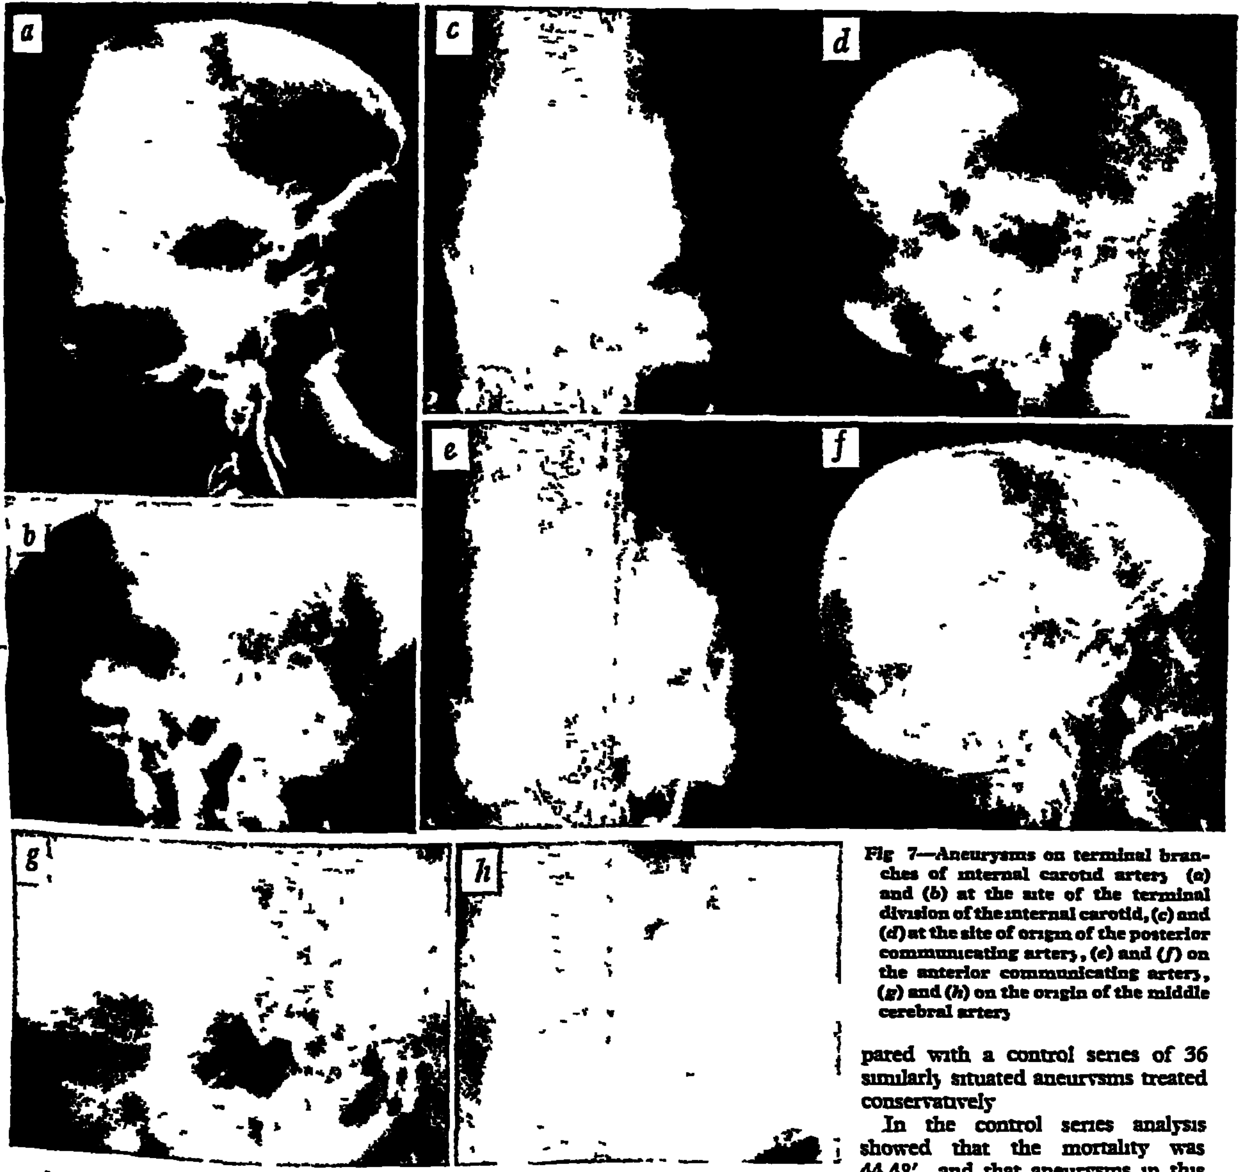

Fig. 7—Aneurysms on terminal branches of internal carotid artery (*a*) and (*b*) at the site of the terminal division of the internal carotid, (*c*) and (*d*) at the site of origin of the posterior communicating artery, (*e*) and (*f*) on the anterior communicating artery, (*g*) and (*h*) on the origin of the middle cerebral artery.

on the surgical treatment of aneurysms of the anterior communicating artery in which they stressed the fundamental importance of the time factor and recognised that two separate problems were involved—namely, treatment in the acute stage of hæmorrhage and treatment in the free interval to minimise the danger of further hæmorrhage. Of their 26 patients, 24 had come under observation on account of a subarachnoid hæmorrhage. 24 were submitted to direct surgical attack on the aneurysm, with 3 deaths (12·5%) at or soon after operation, and another patient died eighteen months later from a further hæmorrhage.

Only 6 cases were operated on within three weeks of the initial hæmorrhage with one operative death, and of these 6 only 4 were operated on within ten days of bleeding.

In 1956 Logue published the results of a more extensive experience in the direct surgical treatment of aneurysms of the anterior cerebral and anterior communicating arteries giving rise to subarachnoid hæmorrhage. He also stressed the importance of considering separately the management of leaking aneurysms according to their anatomical situation and of relating the operative results to the interval between hæmorrhage and surgical treatment.

His series consisted of 37 cases treated by one particular type of surgical operation—i.e., proximal clipping of the anterior cerebral artery supplying the sac—and the results were compared with a control series of 36 similarly situated aneurysms treated conservatively.

In the control series analysis showed that the mortality was 44·4%, and that aneurysms in this situation seldom kill at their first hæmorrhage but tend to bleed again with fatal results during the six weeks after the initial hæmorrhage, with a peak period in the second week. Of the 20 patients who survived on conservative treatment 4 (i.e., 11% of the whole) were left with severe and lasting disabilities.

Of the 37 cases submitted to surgical treatment the overall mortality was 13·5% as opposed to 44·4% in the control series. Of the 30 survivors, 3 (i.e., 8% of the whole) were left with severe residual disabilities. Putting these figures into terms of functional recovery, of the 36 patients treated conservatively 16 were able to resume a virtually normal life, while for the 37 cases treated surgically the corresponding figure was 24 with a further 3 steadily improving at the time of publication.

From his experience of this well-controlled series of comparable cases treated by a single method, Logue concludes that at present the best treatment of bleeding aneurysms at this site (which represent 20–30% of all such cases) is to investigate them as soon as possible after the initial hæmorrhage and then to operate upon them as soon as the immediate effects of this hæmorrhage have subsided and before there has been time for a recurrence—i.e., about seven to ten days after the initial leakage.

Later in 1956 McKissock and Walsh published their results of treatment of a series of 249 cases of subarachnoid hæmorrhage resulting from verified aneurysms. They also stressed the importance of subdividing such cases according to the anatomical site of the aneurysm and in respect of the time that had elapsed since the last hæmorrhage While recognising that the mortality in cases operated on during the stage of acute bleeding would inevitably be high, they believed and sought to demonstrate that, even so, it was appreciably lower than it would have been in the same cases had they been treated conservatively They also recognised that there was risk of their deductions from their results being distorted by the element of selection, and so compared their operative results not only with a comparable number of their own cases treated conservatively but with the results of other series treated conservatively

McKissock and Walsh do not give the precise grounds on which patients were selected for surgical or conservative treatment but state that the choice was largely determined by the date at which the patient was admitted—i e, whether before or after the date on which a more active policy was embarked upon

They established a routine procedure for cases admitted for subarachnoid hæmorrhage Provided that the patient successfully withstood compression of each common carotid artery in turn for ten minutes, bilateral carotid angiography was carried out In the event of an aneurysm being demonstrated, the appropriate operation according to its site was carried out immediately For the purpose of assessing the operative results the patients were divided into three categories according to their clinical condition, on admission in the case of those treated conservatively, and at operation in the case of those treated surgically

Category A—Comprised patients in danger of dying in the immediate future from the hæmorrhage causing admission This included all cases in coma and semicoma and those with severe neurological signs

Category B—Comprised patients who had completely or partly recovered from the results of the hæmorrhage leading to admission but were within a period of eight weeks from it and so were to be considered in considerable danger of a recurrent and possibly fatal hæmorrhage

Category C comprised patients admitted more than eight weeks after the hæmorrhage and who were thus at only moderate risk of a recurrence (20% according to Hyland's [1950] figures)

Comparing the results of conservative and operative treatment in these three categories, their results were as follows

Category A—In 43 cases treated conservatively the mortality was 90% In 52 cases treated surgically the mortality was 65 5%

Category B—In 48 cases treated conservatively the mortality was 37 5% In 72 cases treated surgically the mortality was 12 5%

Category C—In 17 cases treated conservatively the mortality was 6% In 17 cases treated surgically the mortality was 23 5%

Studying these figures critically one notices that the operative mortality for cases in Category A was 65 5%, compared with 50-60% in published series of subarachnoid hæmorrhage of all types and 90% in McKissock and Walsh's control series of cases in the same category Operation under these circumstances can therefore only be justified on the assumption that the expected mortality for cases falling into category A if treated conservatively is much higher than the average for all subarachnoid hæmorrhages and that the mortality-rate of 90% in McKissock and Walsh's control series is truly representative To me these assumptions seem reasonable but not everyone will agree, and the desirability of operating at the height of hæmorrhage remains sub judice

As regards category B, the operative mortality of 12 5% as compared with that of 37 5% in the control series and the 50–60% overall mortality in published cases of subarachnoid hæmorrhage is convincing and is in conformity with the results of Norlen and Barnum (1953) and of Logue (1956) in respect of one particular group of aneurysms—namely, those arising from the anterior communicating or anterior cerebral arteries

As regards category C, in reference to their mortality of 23 5% in 17 cases, McKissock and Walsh explain that the 4 deaths resulted from recurrent hæmorrhages at two years (1), eighteen months (2), and six weeks (1) after simple carotid ligation and that there were no deaths from the immediate effects of operation They no longer consider carotid ligation alone to be adequate treatment for such cases

Considering their material from the point of view of functional results, as well as survival, McKissock and Walsh point out that of 108 patients treated conservatively 51 (46%) survived, of whom only 1 was severely disabled, whereas in the 141 cases treated surgically 94 (67%) survived but 16 were severely disabled

McKissock and Walsh, using the same clinical categories, then broke down their material on the basis of the anatomical site of the aneurysms, different surgical techniques being employed in respect of aneurysms in different sites In subdividing the cases into so many subsections the numbers naturally become much smaller and conclusions more open to error, but these workers conclude that group for group those treated surgically showed a lower mortality than those treated conservatively

Certain conclusions can legitimately be drawn from these various contributions Firstly, subarachnoid hæmorrhage treated conservatively carries a grievous mortality Secondly, active treatment can be logically applied only after an accurate diagnosis has been made and this involves bilateral carotid angiography, which should be carried out as soon as possible Thirdly, those cases within eight weeks of their hæmorrhage are, in the absence of some special contraindication, best treated by surgical means either by direct attack on the aneurysm or by some variety of carotid ligation Fourthly, if more than eight weeks have elapsed since the last hæmorrhage, conservative treatment is usually to be preferred to surgical treatment The question of whether surgical treatment is indicated during the phase of acute hæmorrhage remains for the future to decide It should be remembered that in none of the series cited was artificial hypothermia generally employed It is now possible, under hypothermia, to cut off the cerebral circulation entirely by clamping the three great branches of the arch of the aorta for up to ten minutes without inflicting lasting damage on the brain, and accordingly it seems almost certain that, within the next few years, further evidence will be forthcoming in favour of early surgical intervention Indeed, in a recent paper Botterell et al (1958) have already described a series of 97 cases of cerebral aneurysm operated upon under artificial hypothermia with compression when necessary of both carotid and both vertebral arteries Of these, 64 were operated upon within seven days of the occurrence of subarachnoid hæmorrhage, with only 19 deaths (30%)

Intracerebral Hæmorrhage

Localised hæmorrhage into the substance of the brain, conveniently referred to as an intracerebral hæmatoma, broadly speaking occurs under two widely different circumstances

(1) By rupture of some pre-existing localised vascular anomaly such as an aneurysm or an angiomatous malformation.

(2) By rupture of an atherosclerotic vessel in a patient suffering from generalised arterial degeneration and usually from hypertension

The second group is the one that raises the more complex questions of diagnosis and treatment

INTRACEREBRAL HÆMATOMAS RESULTING FROM RUPTURED ANEURYSMS

The rupture of a cerebral aneurysm commonly gives rise to a subarachnoid hæmorrhage When, however, the aneurysm is buried within the substance of the brain, as is not uncommon in those arising from the anterior or middle cerebral arteries, some and occasionally all of the shed blood ploughs up the surrounding brain tissue and gives rise to an intracerebral hæmatoma, often of considerable size.

This complication is frequently encountered in the surgical treatment of subarachnoid hæmorrhage, and its presence can often be suspected from the clinical picture of rapidly or slowly developing signs of a space-occupying lesion with papillœdema and other signs of a sustained increase of intracranial pressure and confirmed by the shift of the cerebral arteries revealed by angiography.

It is generally agreed that the presence of a massive intracerebral clot in cases of subarachnoid hæmorrhage is a further indication for surgical intervention at the appropriate time.

INTRACEREBRAL HÆMATOMAS RESULTING FROM ANGIOMATOUS MALFORMATIONS

Intracerebral hæmatomas arising from leaking or ruptured angiomatous malformations present a somewhat different problem. They commonly occur in healthy young adults or adolescents and usually develop somewhat more slowly and less catastrophically than those due to ruptured aneurysms. They may or may not have been preceded by events suggestive of a subarachnoid hæmorrhage or of some space-occupying cerebral lesion—for example, by fits or signs of focal brain disease. According to MacKenzie (1953) 30% of angiomatous malformations present with symptoms of hæmorrhage either subarachnoid or intracerebral or a combination of the two.

The diagnosis of an intracerebral hæmatoma of this type depends upon the clinical findings of a rapidly developing expanding intracranial lesion in an otherwise healthy person, especially if additional features suggestive of hæmorrhage are present. The diagnosis is confirmed by angiography which, in addition to showing evidence of displacement of the cerebral vessels, reveals the characteristic features of the causative lesion.

Such hæmatomas should be treated surgically, at the earliest opportunity, by evacuation of the clot and excision of the angiomatous malformation if this is possible—which it usually now is thanks to the pioneer work of Olivecrona and Riives (1948). The recovery in such cases is usually gratifying in the extreme, as the following case illustrates.

Case 7.—A healthy postman, aged 30, had probably had a fit after a drinking bout when about 18 years of age. From that time he was liable to occasional headaches, but in other respects remained well until three weeks before admission when he suddenly developed a severe frontal headache and within a few seconds was aware of weakness of his left leg. This within a few minutes developed into a complete left hemiplegia. There was no disturbance of consciousness or aphasia but he had retention of urine for five days.

On examination three weeks later he had a severe left hemiplegia but slight voluntary movement was now present at hip and shoulder. The cerebrospinal fluid (C.S.F.) was yellow and under slightly increased pressure. The E.E.G. showed abnormal slow waves in the anterior part of the right hemisphere. A right carotid angiogram revealed a small angioma, just anterior to the central sulcus, deriving its blood from the hypertrophied right anterior cerebral artery. At operation a small angiomatous malformation was found and excised, and an intracerebral hæmatoma was encountered and evacuated leaving a ragged cavity in the brain 5 cm. in depth and 5 cm. in anteroposterior extent.

The patient made an uninterrupted recovery, and five years later his only remaining disability is slight weakness of dorsiflexion of the left foot.

INTRACEREBRAL HÆMATOMAS RESULTING FROM CEREBRAL VASCULAR DEGENERATION WITH HYPERTENSION

Massive intracerebral hæmorrhage in patients suffering from diffuse vascular disease with hypertension is a common and usually a terminal event. In most such cases the hæmorrhage bursts through into the ventricular cavities or on to the surface of the brain, and the bleeding continues until the patient dies. But not all such patients die in the first attack, for evidence of old intracerebral hæmorrhages is often seen at necropsy. Some live on, with varying degrees of disability, until another stroke dispatches them or until they die from some other cause, and they may survive for a long time.

In the past such patients were considered to be beyond human aid and an atmosphere of pessimism hung over their misfortunes, for it was only a matter of time before some further catastrophe overwhelmed them. But today some cases of hypertension can be cured and others can be controlled, and the question therefore arises as to whether anything surgical can be done to mitigate the consequences of such a lesion in patients who survive the initial disaster.

The first problem is clearly that of recognising the presence of an intracerebral hæmatoma, which is by no means easy. The differential diagnosis is usually from cerebral softening through infarction.

The patient is commonly a *middle-aged or elderly* person with the usual features of diffuse arterial disease with hypertension. The onset is often ingravescent, neither as dramatic as with the usual massive hæmorrhage nor as silent as with a thrombosis. Headache is usually severe and depression of consciousness is the rule. There may be bradycardia. These lesions are commoner in the posterior parts of the hemisphere, so the local signs usually include hemianopia and sensory disturbance as well as hemiplegia. Where the major hemisphere is involved severe dysphasia is the rule. After a few days, when a patient with an uncontrolled hæmorrhage is likely to have died and one with a massive softening to be improving, the patient with an intracerebral hæmatoma is still sinking into deeper coma, and papillœdema and other signs of increased intracranial pressure may make their appearance. The C.S.F. is under increased pressure and often xanthochromic and may be lightly bloodstained. Untreated, the patient either expires in coma in the second or third week of his illness or gradually struggles back to a normal level of consciousness and survives with a varying degree of damage to body and mind.

If an intracerebral hæmatoma is suspected its presence can often be confirmed by X-ray examination of the skull, which may show the characteristic shift of the pineal shadow away from the side of the hæmatoma. Alternatively an air ventriculogram may be needed to demonstrate the presence of an expanding intracranial lesion and the hæmatoma may be encountered in performing it.

Surgical evacuation of such hæmatomas has been reported in the literature at intervals since the first was reported by Cushing in 1903, and others later by Russell and Sargent (1909) and by Penfield (1933). But the presence of generalised arterial disease and hypertension has more often been regarded as a contraindication to surgical intervention.

In 1941 Furlow et al. reported 5 cases of intracerebral hæmatoma evacuated surgically, of which 3 were secondary to hypertension. They considered that operation was justified where improvement failed to occur with conservative measures, where symptoms and signs of raised intracranial pressure made their appearance, and where the general condition of the patient's cardiovascular system was not so serious as to contraindicate it. The ætiology and symptoms of intracerebral hæmatoma were fully reviewed by Jewesbury in 1947. In

1953 Diana Beck reported on 6 cases of intracerebral hæmatoma treated by evacuation, of which 5 were associated with moderate or severe arterial hypertension In 1957 Gurdjian and Webster reported 11 cases operated upon, of which 6 were in patients over 50 years of age, and of these 6 patients 4 were hypertensive Kelly (1958) has recently reviewed the clinical features of 34 cases, many resulting from hypertension, with especial reference to the results of surgical evacuation of intracerebral clots

I have come to the conclusion that surgical treatment has an undoubted part to play both as a life-saving measure and as means of minimising the residual disability in certain selected cases of intracerebral hæmorrhage resulting from hypertension in atherosclerotic subjects

Case 8—A business man of 48 had been known for some years to be hypertensive, and four months previously had suffered from transient hæmaturia Six days before admission, while abroad, he woke with severe headache and nausea He became confused and incontinent and developed dysphasia and a right hemiparesis Within four hours he had become semicomatose and was admitted to a hospital from which he was transferred to the National Hospital two days later

On examination he was drowsy but could be roused sufficiently to obey simple commands He was dysphasic, had a right homonomous hemianopia and a virtually complete right hemiplegia with considerable sensory loss The optic fundi showed bilateral papillœdema His heart was enlarged, blood-pressure 170/120 mm Hg, his urine contained considerable albumin X-ray examination of the skull showed the pineal body deviated towards the right, and ventriculography showed a large expanding lesion in the left temperoparietal region From this, old blood was withdrawn, and at operation a large intracerebral hæmatoma was evacuated

He made a steady and uninterrupted recovery On discharge from hospital six weeks later he was fully alert, his papillœdema had subsided, and his right-sided weakness and sensory disturbance and dysphasia had almost disappeared There was still a partial hemianopia and some mental impoverishment

During the next two years he continued to improve and led an active life at home, although he was not able to return to business He then suffered a recurrence of his headache with return of his dysphasia and right hemiparesis, but without depression of consciousness or other signs of increased intracranial pressure His blood-pressure was 180/140 mm Hg He again improved, this time spontaneously, and left hospital little altered by his second attack except for further reduction of his mental capacity Seen in recent weeks, nearly four years after his initial hæmorrhage, his condition remains much the same

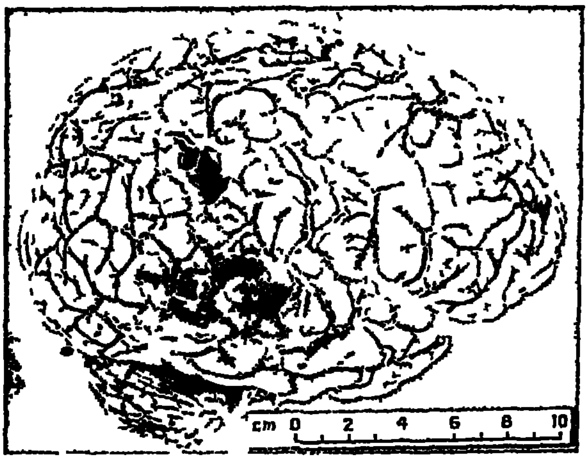

Fig 8—Surface view of the right hemisphere in case 9, showing old bloodstaining of the pia mater over the site of evacuation of an intracerebral hæmatoma

Case 9.—A university lecturer, aged 52, had been known to be severely hypertensive for some years, and over the course of ten years had experienced several hæmatemeses from a pyloric ulcer He was right-handed Three weeks before admission he had experienced sudden numbness on the left side of his face with clumsiness of his left hand, which had cleared up in two or three days Two weeks later he developed weakness of his left arm and leg which rapidly progressed to a complete hemiplegia with increasing drowsiness and severe headache

On examination he had a severe left hemiparesis with sensory loss and a left homonomous hemianopia His fundi showed advanced arterial changes, his heart was enlarged, and his blood-pressure 260/160 mm Hg X-ray examination showed shift of the pineal body to the left, and in attempting ventriculography a blood clot was encountered by the cannula in the right posterior parietal region As much blood as could be withdrawn was aspirated Temporary improvement followed, but as this was not maintained a bone flap was turned down four days later and 20 ml of solid clot was evacuated

From this time his cerebral condition steadily improved, in spite of a further gastrointestinal hæmorrhage sufficiently severe to demand transfusion On discharge two months after admission he was ambulant with a diminishing hemiparesis and hemianopia, and six months after his stroke he was able to return to light duties in his college His blood-pressure remained in the region of 250/150 mm Hg

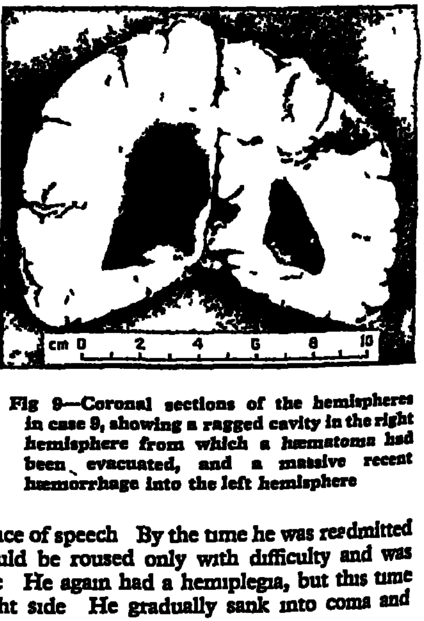

Fig 9—Coronal sections of the hemispheres in case 9, showing a ragged cavity in the right hemisphere from which a hæmatoma had been evacuated, and a massive recent hæmorrhage into the left hemisphere

Approximately a year after his first stroke he suffered a second This came on while he was in bed and was heralded by disturbance of speech By the time he was readmitted to hospital he could be roused only with difficulty and was severely dysphasic He again had a hemiplegia, but this time it was on the right side He gradually sank into coma and died five days after readmission

Necropsy showed evidence of advanced atherosclerosis with cardiomegaly The right cerebral hemisphere showed old bloodstaining under the pia in the right parietal region which was in contact with a well-healed surgical flap in the dura mater and skull An incision in the cortex led to a narrow, ragged cavity in the walls of which there was old bloodstaining The corresponding region of the left hemisphere was occupied by a large recent hæmorrhage which had burst through into the lateral ventricle (figs 8 and 9)

In evaluating these and similar cases we encounter the old difficulty that no-one can say with certainty what would have happened had the patients not been subjected to operation From experience of similar cases I think it is very unlikely that either of those two patients would otherwise have survived the initial stroke, and I am even more certain that if they had been treated conservatively the neurological damage, had they survived, would have been greater Whether the prolongation of life in these cases was desirable or not is a matter of opinion They have been selected for reference because in each case the ultimate prognosis was as bad as it could be, and to many would have constituted a contraindication to any form of surgical treatment.

Conclusions

I have now completed my review and it remains only to draw some general conclusions from it I hope it has been shown that modern surgery and a variety of technical procedures have been brought to bear significantly on the problems of cerebral vascular disease For many years this subject has been at an impasse which has engendered an atmosphere of fatalism and inertia Today there are signs of advance in a number of directions and an attitude of passive acceptance is giving place to one of active inquiry and experiment Although at present modern methods of treatment may only touch the fringe of the problem, it is a growing fringe and every attempt to enlarge it should be encouraged.

This will not be easy, for the idea that cerebral vascular disease is exclusively a medical disorder is deeply ingrained in most of us As physicians we instinctively hesitate to precipitate our patients into the hazards of surgery, the more so in a condition where the initial symptoms we observe are so often both mild and transient A more progressive attitude will give rise to administrative problems The correct handling of cases of cerebral vascular disease will come to depend more and more upon accurate diagnosis This in its turn will necessitate the use of diagnostic procedures which can be carried out only in suitably equipped hospitals which have a highly trained specialist staff available at all times It must, therefore, be expected that a steadily increasing number of cases of cerebral vascular disease will have to be transferred, often at short notice, to specialised centres for investigation and treatment. It is only at such centres that new methods can be tested under satisfactory conditions and advances in treatment achieved Mistakes will inevitably be made, but, bearing in mind the outcome of conservative treatment, we cannot afford to be either timid or complacent

I wish to thank my hospital colleagues for permission to refer to the records of patients under their care, Dr William Blackwood and Dr James Bull for their help in providing pathological and radiological material, and the authorities of the University of California through whose generosity I was afforded the leisure and the facilities without which it would have been difficult to prepare these lectures

with the technical assistance of

D L CORKIN

From the Department of Microbiology,
the Queen's University of Belfast

INTRADERMAL vaccination with formalinised poliomyelitis vaccine has been used over the past three years in Denmark, where an estimated 91% of the population between the ages of nine months and forty years have received two doses (von Magnus 1957) Recently Sigurdsson, Gudnadottir, and Petursson (1958) reported their experience with this method in Iceland Since only about one-third the quantity is required for the intradermal as compared with the intramuscular route, its use is important if vaccine is in short supply This paper records an investigation of the efficacy of the intradermal method in young children

Numerous observations have shown that oral administration of certain toxoids or suspensions of killed bacteria can stimulate antibody production (Wilson and Miles 1955) Although this method is far less efficient than parenteral administration, we also decided to attempt immunisation by mouth with killed poliomyelitis vaccine since this is simple

Materials and Methods

British poliomyelitis vaccine 'Polivirin' manufactured by Glaxo Laboratories was used This contains formalinised Brunenders, MEF$_1$, and Saukett strains of polioviruses The methods of administration were

Intradermal—Two doses, each of 0 3 ml of vaccine, were given at four weeks' interval Each dose was halved so that two injections were given into the flexor aspect of each forearm

Oral—Two doses, each of 5 ml, were given in milk at four weeks' interval

Intramuscular—Two doses, each of 1 ml, were given at four weeks' interval

In the first trial, blood samples were taken on the day of vaccination and two weeks later Further blood samples were obtained four weeks after the first dose and four weeks after the second dose In the second and third trials blood samples were obtained on the day the first dose of vaccine was given and again four weeks after the second dose

Tissue-culture techniques and virus-neutralisation tests were similar to those described by Dane, Dick, Connolly, Fisher, and McKeown (1957) Children were considered to have no demonstrable antibody when a 1/4 dilution of sera failed to neutralise 100 TCD$_{50}$ of poliovirus Sera were not titrated beyond a dilution of 1/512 Virus-isolation techniques were similar to those described by Dick, Dane, Fisher, Connolly, and McKeown (1957)

Results

Children of five years of age and under were selected for study since in Northern Ireland they are the age-group most susceptible to paralytic poliomyelitis In the first trial, during May, 1957, 7 children were vaccinated intradermally and 7 others received vaccine by mouth As a control, a further 8 children were vaccinated intramuscularly In the second trial, in November, 1957, 15 children received vaccine intradermally, and in the third trial in January, 1958, another 30 were vaccinated intradermally The age distribution and sex of these children are shown in table I

Intradermal Vaccination

We first studied children who before vaccination were devoid of antibody to all three poliovirus types The antibody response of these triple-negative children four weeks after the second intradermal dose is shown in table II

It will be seen that 3 children devoid of antibody before vaccination remained so and that no child developed demonstrable type-1 antibody

We next studied the antibody response in children who were initially devoid of antibody to one of the three poliovirus types The antibody response four weeks after the second intradermal dose is shown in table III and fig 1

TABLE I—THE AGE DISTRIBUTION AND SEX OF THE CHILDREN IN THE THREE TRIALS

Route of administration of vaccine	No of children in each age-group					Sex		Total
	1–2	2–3	3–4	4–5	5–6	M	F	
Intradermal	12	24	5	8	3	30	22	52
Oral	1	2	3	1	0	4	3	7
Intramuscular	0	4	2	1	1	2	6	8

TABLE II—THE ANTIBODY RESPONSE 4 WEEKS AFTER TWO INTRADERMAL DOSES OF VACCINE IN CHILDREN INITIALLY DEVOID OF ANTIBODY TO ALL 3 POLIOVIRUS TYPES

No of children without antibody to any poliovirus type	No of children with antibody response to			No of children without antibody to any poliovirus type after vaccination
	type 1	type 2	type 3	
5	0	2	2	3

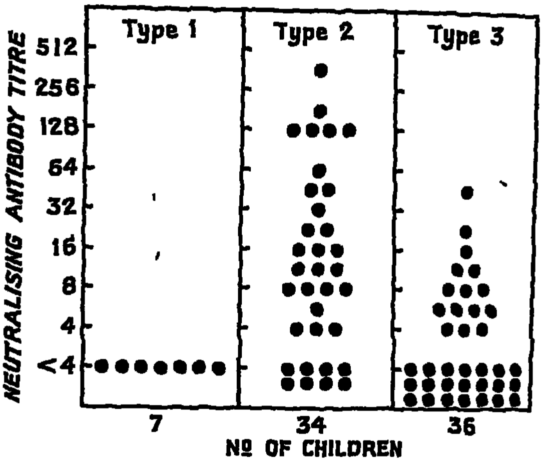

Fig 1—The antibody response 4 weeks after two intradermal doses of vaccine in children initially devoid of antibody to 1 of the 3 poliovirus types

It will be seen that, again, no child produced any demonstrable type-1 antibody The proportion of children producing type-2 antibody was highest The number of children in this age group who were initially devoid of type-1 antibody is small, possibly because of an epidemic of type-1 poliomyelitis in Northern Ireland in the summer of 1957

The antibody response four weeks after the second intradermal dose in children who possessed naturally acquired antibody at the time of vaccination is shown in table IV and fig 2

It will be seen that in most cases the pre-existing antibody is boosted to higher levels by intradermal vaccination. In 3 children the type-1 antibody was not boosted, in 2 the type-2 antibody was not boosted, and in 1 the type-3 antibody was not boosted

Of the control group of 8 children, 5 had no type-1 antibody and 1 had no antibody to any of the three poliovirus types Four weeks after the second intramuscular dose of vaccine only 1 child had not produced any type-1 antibody, while all children of this group showed a type-2 and type-3 antibody response

TABLE III—THE ANTIBODY RESPONSE 4 WEEKS AFTER TWO INTRADERMAL DOSES OF VACCINE IN CHILDREN INITIALLY DEVOID OF ANTIBODY TO ONE OF THE 3 POLIOVIRUS TYPES

Antibody type	No of children without antibody	No of children developing antibody	Percentage antibody response
1	7	0	0
2	34	26	76
3	36	15	42

TABLE IV—THE ANTIBODY RESPONSE 4 WEEKS AFTER TWO INTRADERMAL DOSES OF VACCINE IN CHILDREN ALREADY POSSESSING ANTIBODY

Antibody type	No of children possessing antibody	No of children showing booster response	Percentage antibody response
1	45*	37	93
2	18†	9	82
3	16‡	14	93

* Five had a prevaccination titre of 512 or more and were excluded

† Seven had a prevaccination titre of > 512 and were excluded

‡ One was excluded since insufficient serum was obtained for estimation of type 3 antibody titre

TABLE V—THE ANTIBODY RESPONSE 4 WEEKS AFTER TWO ORAL DOSES OF VACCINE

No of children given oral vaccine	No of children with antibody response to			No of children without antibody response to any poliovirus type
	type 1	type 2	type 3	
7*	1	3	1	4

* A fourth sample of serum was not obtained from one child

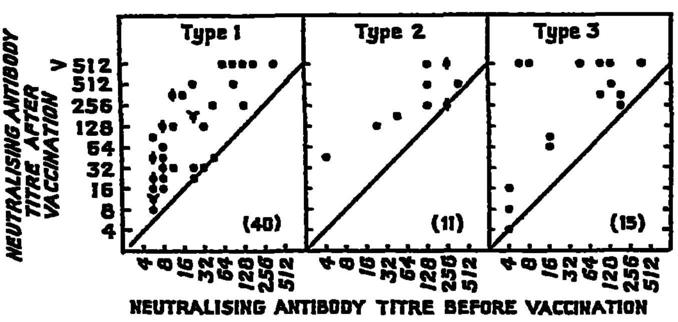

Fig 2—The antibody response 4 weeks after two intradermal doses of vaccine in children already possessing antibody

Oral Administration

The antibody response in 7 children who were given two doses of vaccine by mouth is shown in table V and fig 3

3 children had no antibody to any of the three poliovirus types before receiving vaccine and all failed to develop antibody The number of children responding to type-2 was greater than the number who responded to either type-1 or type-3

After each oral dose of vaccine fæcal samples were collected for ten days to exclude coincidental natural poliomyelitis infection. Because live virus was not detected, it was concluded that the antibody responses in this group were due to the vaccine Children who failed to respond to intradermal or oral administration were later vaccinated intramuscularly

Discussion

In children devoid of antibody to all three poliovirus types there was a poor response to intradermal vaccination (table II) This contrasts with the findings of von Magnus (1957) who in one trial showed that, of 6 children devoid of antibody to all three poliovirus types, 4 developed type-1 antibody and all developed type-2 and type-3 antibodies after two doses of 0·2–0·3 ml of vaccine at four weeks' interval Salk (1955) has shown that the antibody response to vaccination is less in children who are initially devoid of antibody to all three poliovirus types than in those who at the time of vaccination possess antibody to one or more poliovirus types

Again our results show a much poorer antibody response than those of von Magnus (1957) in children who at the time of vaccination were devoid of antibody to any one of the three poliovirus types (table III and fig 1) In the Danish trial of children initially devoid of antibody to one poliovirus type, 21 out of 30 developed type-1 antibody, all of 32 developed type-2 antibody, and 34 out of 35 developed type-3 antibody. Sigurdsson et al (1958) obtained a poor antibody response in Icelandic children who, when vaccinated intradermally, were devoid of antibody

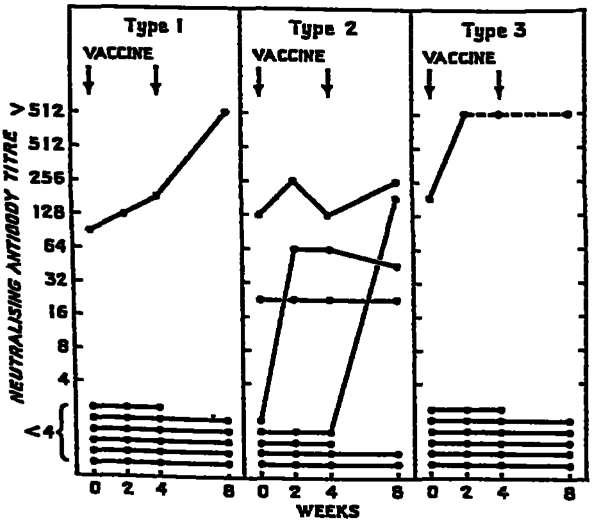

Fig 3—The antibody response 4 weeks after two oral doses of vaccine.

Our results show that in most cases a booster response occurs in children already possessing naturally acquired antibody

In assessing the results of vaccination it is important to know the antigenicity of the vaccine used The British vaccine was tested by the manufacturer and the Medical Research Council before it was released Dr W Wood informed us that, in the batches of vaccine used, the type-2 component was more antigenic than either the type-1 or type-3 component when tested in rhesus monkeys This may account for more children showing a type-2 antibody response as seen in table III and table V Salk (1955), however, has shown that the type-2 antibody response is enhanced by the presence of type-1 antibody and to a lesser degree by the presence of type-3 antibody Of those children vaccinated intradermally who were devoid of type-2 antibody, 27 had type-1 antibody and 8 had type-3 antibody The heightened type-2 antibody response may therefore be related to the presence of type-1 antibody. Salk (1957) has further shown that the proportion of people who respond to a vaccine, and the degree of response, is related to the mass of antigen administered He demonstrated that the booster response to an intramuscular dose of 1 ml. was lower in those who initially had been vaccinated with two intradermal doses each of 0·1 ml at two weeks' interval than after two intramuscular doses of 1 ml He concluded that the intradermal method does not increase the efficiency of the antibody response sufficiently to permit reduction in the quantity of vaccine without sacrificing the effect in people who require more than very small quantities to produce an antibody response While a third intradermal dose of vaccine may increase the number of people who respond (von Magnus 1957) it seems unlikely that the number responding will ever be so large, or the antibody titres so high, as in those who received a greater mass of antigen intramuscularly It therefore appears that, in the absence of a more potent vaccine, the intradermal method has little to commend it for primary vaccination.

The response to formalinised poliomyelitis vaccine by mouth was poor, but the type-2 component appeared to be most antigenic. Because poliomyelitis is primarily an alimentary infection, Sabin (1956), Koprowski et al (1956), Dane et al (1957), and Dick et al (1957) gave living attenuated poliomyelitis vaccines by mouth and antibody was subsequently produced. It is interesting that oral non-replicating polioviruses induced an antibody response in some children, and possibly the response might improve by using a larger dose or a more potent vaccine.

Summary

52 children under the age of five were given two intradermal doses of formalinised poliomyelitis vaccine and the antibody response was studied This method was found to be unsatisfactory for primary vaccination in children initially devoid of antibody Most children who possessed naturally acquired antibody showed a booster response

Although an antibody response occurred in some children after two oral doses of formalinised poliomyelitis vaccine, this method has no practical application at present

We wish to thank the parents who gave consent for their children to take part in these trials, also Dr B R Clarke, Dr Sheila Balmer, and Dr W J McLeod who gave valuable assistance The work was supported by grants from the National Fund for Poliomyelitis Research, the Medical Research Council, and the Northern Ireland Hospitals Authority

One of us (J H C) was in receipt of a fellowship from the National Fund for Poliomyelitis Research during part of this study

AMONG diabetic patients a group can be recognised in which, besides hyperglycæmia and glycosuria, ketosis and rapid loss of weight usually develop unless insulin is injected In a study of the plasma-insulin activity in these patients using the rat diaphragm technique, it has been shown that, if the blood-sugar level is raised at the time of the test, no plasma-insulin activity is found Moreover, when insulin is added in vitro to the plasma from these patients its activity is apparently inhibited (Vallance-Owen et al 1955)

Plasma from normal subjects shows insulin activity and, when a known amount of insulin is added to the plasma in vitro, the activity of the added insulin is not diminished —i e, there is no measurable antagonism (Vallance-Owen and Hurlock 1954) Nevertheless there is evidence that normal plasma contains an insulin antagonist, the action of which is masked Thus if a normal cat is pancreatectomised, the plasma, which was previously inactive in the rat-diaphragm test, then antagonises added insulin (Vallance-Owen and Lukens 1957)

The experiments reported here were undertaken in an attempt to determine the chemical nature of the insulin antagonist, and to elucidate its mode of action

Materials and Methods

Plasma

Venous blood was withdrawn into a heparinised syringe from non-fasting normal subjects and uncontrolled insulin-requiring diabetics who had received their last injection of soluble insulin at least 15 hours previously The plasma was quickly separated by centrifugation

Salt Fractionation of Plasma-proteins

Sodium sulphate (27% w/v) solution in phosphate buffer (pH 7 8, I=0 1) was added either to the fresh plasma or to reconstituted freeze-dried plasma to give various concentrations of the final solution between 15% and 22% The precipitates were removed by centrifugation, and both fractions were dialysed against distilled water and freeze-dried

Preparation of Albumin

Albumin was obtained from plasma by the trichloroacetic acid-ethanol procedure of Debro et al (1957) In this procedure the 1% trichloroacetic acid (T C A) in 96% aq ethanol is added to 0 5 ml of plasma to a final volume of 10 ml The precipitate is removed by centrifugation, and the supernatant dialysed and freeze-dried Later a modification of this procedure was adopted as follows

An equal volume of 10% T C A (w/v) was added to the plasma, the supernatant after centrifugation was discarded, and the precipitate washed with 5% T C A The precipitate was then suspended in 1% T C A 96% aq ethanol in a volume *equivalent to three times the* original volume of plasma After centrifugation the extract was dialysed and freeze-dried

Characterisation of the Plasma-protein Fractions

The fractions were subjected to paper electrophoresis in 'Veronal' buffer according to the method of Flynn and de Mayo (1951)

Measurement of Insulin Antagonism

Insulin antagonism was determined by the rat diaphragm assay procedure previously described (Vallance-Owen and Hurlock 1954, Vallance-Owen et al 1955)

The freeze-dried fractions obtained were dissolved in buffer solution (Gey and Gey 1936) containing glucose (300 mg per 100 ml) Unless otherwise stated, the salt fractionated plasma proteins were dissolved at approximately the same concentration as they occurred in the original plasma

Insulin was added to the buffer alone and to the buffer with the dissolved fraction to make a final concentration of 1000 micro-units per ml

In any one experiment the glucose uptake of the diaphragm was determined in (*a*) buffer alone (basal uptake), (*b*) buffer plus added insulin (standard), (*c*) buffer with dissolved fraction plus added insulin The uptake was ordinarily measured three times in each solution, diaphragms from three different rats being used

Results

Fractionation of Diabetic Plasma-proteins

As was found previously, full saturation of the diabetic plasma with sodium chloride precipitated the antagonistic activity of the plasma (Vallance-Owen and Lukens 1957) The active precipitate did not contain α_1-globulin but did contain a substantial amount of albumin Owing to the poor fractionation of the plasma-proteins by this method, sodium sulphate was employed in subsequent experiments The activity of the fractions obtained by sodium-

TABLE I—INSULIN ANTAGONISM OF FRACTIONS FROM DIABETIC PLASMA

Fraction	Mean glucose uptake above basal level ± standard error of the mean (mg per 100 ml per 10 mg diaphragm)

Number of observations in parentheses

---

* In receipt of a grant from the Medical Research Council

sulphate fractionation of diabetic plasma is shown in table I This shows that the precipitate obtained by saturation with 18% sodium sulphate was devoid of antagonistic activity, whereas the supernatant had such activity

Paper electrophoresis showed that the sodium-sulphate fractionation effected a complete separation of the γ-globulin and albumin fractions—i e, all the γ-globulin was in the precipitate and all the albumin in the supernatant. The other globulin components of the plasma were present in both fractions It was concluded that the antagonistic activity was not associated with the γ-globulin fraction

Attempts to fractionate the antagonistic activity of the supernatant from 18% sodium sulphate by higher concentrations of sodium sulphate were not successful (table I) These results were consistent with the idea that the activity was associated with the albumin in the diabetic plasma. Albumin was, therefore, prepared from diabetic plasma by the T C.A.-ethanol method of Debro et al (1957) As will be seen from table I, this albumin antagonised the effect of added insulin. The inhibition of the added insulin was complete when the concentration of albumin in the buffer was between 3 5% and 5 5% which includes the physiological range. When the concentration was reduced to 1 25% there was still distinct antagonism of the added insulin Paper electrophoresis of these albumin fractions failed to reveal any other plasma-protein.

TABLE II—INSULIN ANTAGONISM OF FRACTIONS FROM NORMAL PLASMA

Fraction	Mean glucose uptake above basal level ± standard error of the mean (mg per 100 ml. per 10 mg diaphragm)	
	Buffer—1000 micro-units per ml insulin	Fraction in buffer—1000 micro-units per ml insulin
Albumin (T C.A.-ethanol) 3·5–5 5%	11·43 ± 0·62 (6)	0·50 ± 0·48 (6)
2·5%	12·63 ± 1·04 (3)	6·60 ± 1·01 (3)
1 25%	11 32 ± 0·74	11 17 ± 0·89 (4)
Albumin (ether fractionation) 5%	12 50 ± 1·40 (2)	2 75 ± 0·45 (2)
Albumin (Cohn Fraction V) 3 5%	12·40 (1)	2·40 (1)
Precipitate from 18% sodium sulphate	11 11 ± 0·34 (4)	15·61 ± 0·70 (4)
Supernatant from 18% sodium sulphate	12·42 ± 0·65 (4)	12 15 ± 0 22 (4)

Number of observations in parentheses

Fractionation of Proteins from Normal Plasma

The demonstration of the presence of an insulin antagonist in the albumin from diabetic plasma prompted us to test the activity of a similar protein fraction from normal plasma. As will be seen in table II, this normal albumin in physiological concentration also had antagonistic activity However, unlike albumin from diabetic plasma, a concentration of 1 25% failed to show any such antagonism. The possibility that this activity of normal plasma-albumin is due to a change in the albumin, associated with the T C.A.-ethanol method of preparation, was tested by examining the activity of two samples of ether-fractionated albumin As is shown in table II, these also inhibited the action of insulin One sample of ethanol-fractionated plasma-albumin (Cohn fraction V) had similar activity The possibility that the antagonistic activity was associated with a substance incapable of precipitation with T C.A.—e g, a polysaccharide—was excluded by changing the method of preparation of the albumin. Thus, when the plasma-proteins were precipitated with 5% T C.A and the albumin was extracted from the washed precipitate with ethanol, this albumin was fully active

TABLE III—EFFECT OF THE SUPERNATANT FROM 18% SODIUM-SULPHATE-FRACTIONATED NORMAL PLASMA ON ALBUMIN FROM DIABETIC PLASMA

Fraction	Mean glucose uptake above basal level ± standard error of the mean (mg per 100 ml per 10 mg diaphragm)	
	Buffer—1000 micro-units per ml. insulin	Fraction in buffer—1000 micro-units per ml insulin
Supernatant from 18% sodium sulphate (7%)—1 25% diabetic albumin	12 38 ± 0·70 (4)	3 20 ± 0·69 (4)

Number of observations in parentheses

Since the albumin from normal plasma inhibited the action of insulin and yet the whole normal plasma did not exhibit any such antagonism, it was of interest to test the activity of fractions obtained from normal plasma by treatment with sodium sulphate. It will be seen from table II that, in contrast with the results with diabetic plasma, the precipitate obtained with 18% sodium sulphate stimulated the activity of insulin, and this supernatant was devoid of antagonistic activity Since the amount of albumin in the supernatant would suffice to inhibit completely 1000 micro-units per ml of insulin, it appears that normal plasma contains a substance which counteracts the antagonistic activity of the albumin This substance could be insulin itself

Effect of Fractions from Normal Plasma on Diabetic Plasma

The failure of the 18% sodium sulphate supernatant from normal plasma to antagonise the activity of added insulin suggested that this fraction might be capable of counteracting the effect obtained with diabetic albumin. That this was not so will be seen from table III This suggests that the amount of substance with insulin-like activity in this normal plasma fraction is just sufficient to counteract the effect of the albumin present

Nature of Insulin Antagonism by Diabetic Albumin

It seems unlikely that the ability of diabetic albumin to counteract the action of insulin on the rat diaphragm is due to a non-specific action on the metabolism of the tissue, for the following reasons (1) the albumin in these physiological concentrations merely reduced the glucose uptake of the diaphragm to that achieved by the tissue in the absence of added insulin, (2) the addition of large amounts of insulin (i e, 10,000 micro-units per ml.) partially counteracted the antagonism of the albumin. The results of the experiments illustrating this point are shown in table IV

Discussion

These observations suggest that the previously described antagonism to insulin found in the plasma of insulin-

TABLE IV—EFFECT OF THE ADDITION OF 10,000 MICRO-UNITS PER ML. INSULIN TO ALBUMIN FROM NORMAL SUBJECTS

Fraction	Mean glucose uptake above basal level ± standard error of the mean (mg per 100 ml per 10 mg diaphragm)	
	Buffer—1000 micro-units per ml insulin	Fraction in buffer—10,000 micro-units per ml insulin
Normal albumin (4%)*	12 33 ± 0·93 (4)	5·93 ± 0·67 (4)

Number of observations in parentheses

* As will be seen from table II albumin at this concentration completely antagonises the effect of insulin at 1000 micro-units per ml.

requiring diabetics resides in the albumin fraction There is apparently similar antagonism in the plasma-albumin from normal subjects However, the albumin fraction from normal subjects is less active in this respect Bornstein and Park (1953) and Hendley et al (1957) studied the plasma of alloxan-diabetic rats They found that there was antagonistic activity in a lipoprotein fraction Owing to the method of preparation of the albumin used in the present experiments it seems most unlikely that the antagonistic activity is associated with a lipoprotein Moreover, the electrophoretic homogeneity of the T C A.-ethanol albumin preparations excludes the possibility that the activity is due to α_1-globulin The homogeneity of such albumin preparations has been repeatedly studied (e g , Schwert 1957) Thus the activity *described here* would seem to be different from that found by Field et al (1957) in the α_1-globulin fraction of the plasma-proteins of severely ketotic diabetic patients

Taylor (1958) has studied the distribution of insulin in fractions of human serum proteins He finds that the maximal activity is in the region of the α_1-globulin when such proteins are subjected to zone electrophoresis, although insulin-like activity is also associated with the β- and γ-globulins These results agree with ours, and explain why the precipitate obtained with 18% sodium sulphate, which contains all the γ-globulin, some of the β-globulin, but no albumin, stimulates the activity of insulin when isolated from normal plasma, but is without activity when isolated from diabetic plasma The inactivity of the 18% sodium sulphate supernatant from normal plasma is probably due to the insulin associated with the α_1-globulin counteracting the effect of the albumin Taylor also reports that the albumin fractions from human serum were inactive with the rat diaphragm test, although radioactivity studies showed that insulin is bound to the albumin even when isolated by the T C A -ethanol method These results are explicable on the basis that the activity of the insulin bound to the albumin is counteracted by the antagonistic activity of the albumin On this basis it is also possible to explain the difference in activity between the diabetic albumin and the normal albumin, for the normal albumin will have some insulin bound to it, whereas the diabetic albumin will be relatively free of insulin

The question as to whether the antagonistic activity is associated with the albumin per se or whether it is due to some substance bound to it must remain open So far it has not been possible to prepare albumin which is devoid of antagonistic activity, but further work is in hand to elucidate this point

In conclusion it would appear that human plasma-albumin preparations are able to counteract the action of insulin in stimulating the uptake of glucose by the rat diaphragm The difference in antagonistic activity between the fractions from normal and diabetic subjects seems to be due to the presence or absence of insulin or an insulin-like substance We suggest that, whatever the site and mode of action of insulin in carbohydrate metabolism, it has first to overcome the antagonistic activity of the plasma-albumin fraction

Summary

Insulin antagonism has been found to reside in the albumin fraction of plasma from uncontrolled insulin-requiring diabetic patients and from normal subjects

The antagonistic activity of the albumin in whole normal plasma is counteracted by some other substa —possibly insulin

At present it is not known whether the antagonism due to albumin itself or to a substance tightly bound to

We wish to thank Professor J McMichael, F R S , and Prof *Dickens*, F R S , for granting facilities for this work, Dr P Ch wood and Dr R A Kekwick for samples of normal human seru albumin, Miss Barbara Kernot for technical assistance, the Med Research Council for a grant for scientific assistance, and Boots P Drug Co for supplies of recrystallised insulin

ARE IMMEDIATE HISTOLOGICAL EXAMINATIONS OF LUMPS IN THE BREAST USEFUL?

A T SANDISON
B Sc , M D St And
LECTURER, UNIVERSITY DEPARTMENT OF PATHOLOGY,
WESTERN INFIRMARY, GLASGOW

IT has been noticed in this hospital that the number requests for immediate examination of lumps in th female breast has been slowly increasing Since thes examinations are rather time-consuming for the pathologist and especially for the laboratory technician, a smal pilot survey of one hundred consecutive cases was undertaken to assess their value as a routine method

A questionnaire was drawn up and completed as far a possible by the pathologist and the surgeon concerned in each instance The information requested included, a well as the patient's name, age, ward, &c , the surgeon's diagnosis (with alternatives) before operation and after examination of the operative specimen, and the pathologist's diagnosis on naked-eye examination, on freehand section by Terry's method (Terry 1927, Lendrum 1951), and on examination of frozen sections stained with hæmalum and eosin In all the cases the final diagnosis was established by conventional paraffin embedding and section

Methods and Material

Technique

Malignancy can often be determined by inspection or, more often, by careful palpation The examination of immediate sections either prepared by Terry's method or frozen is facilitated by using a very bright source of light The most valuable microscope objective is the scanning (40 mm x 4, supplied by Watson's of London), this gives an excellent topographical view of the mammary architecture which is so important in this form of microscopy This can be ideally combined with a X6

TABLE I—AGE-DISTRIBUTION

Age (yr)	Present series (100 cases)	Large series (1010 cases)
20–29	2%	7%
30–39	14%	15%
40–49	52%	32%
50–59	19%	18%
60–69	7%	14%
70–79	5%	7%
80–89	1%	1%

TABLE II—DIAGNOSES ON PARAFFIN SECTION

—	Present series (100 cases)	Large series (1010 cases)
Carcinoma	50%	50%
Fibrocystic	26%	15%
Hyperplastic cystic (epitheliosis)	10%	10%
Fibroadenoma	5%	10%
Fat-necrosis	4%	1%
Involutional change	2%	—
Papilloma	1%	4%
Inflammation	1%	3%
Leiomyoma of skin	1%	—

long-focus wide-angle eyepiece (or eyepieces if a binocular microscope is used)—e g , the 'Complec' (Watson) or the 'Telaugic' (Swift)

Age of Patients

The age-distribution of the patients is shown in table I For comparison the ages in a larger consecutive series of breast operations in the Western Infirmary, Glasgow, are also given (Sandison 1958) It will be seen that immediate examination was requested in women of widely varied ages The highest incidence of request falls in the fifth decade of life

Type of Case

Table II shows the final diagnosis, and again the larger series is given for comparison In both series carcinoma accounted for 50% of cases Immediate examination was requested for a higher proportion of lumps which proved to be fibrocystic disease and for a smaller proportion proving to be fibroadenoma, papilloma, or inflammation

Results

Diagnostic Errors of Surgeon

These are shown in table III The surgeon was wrong in 25% of preoperative diagnoses, and a wrong diagnosis of malignancy (16%) was commoner than failure to diagnose malignancy (9%) At operation no opinion was given in 3%, but the diagnostic error was much reduced (9%), and failure to diagnose malignancy (6%) was commoner than wrong diagnosis of malignancy (3%) In 3 of the failures to diagnose malignancy the pathologist's diagnosis was also wrong on naked-eye examination

Diagnostic Errors of Pathologist

These are shown in table IV

Naked-eye examination —The pathologist improved slightly on the surgeon's rate of diagnostic error—6% against 9% Most of these errors were failure to diagnose malignancy (5%), and in only 1% was a wrong diagnosis of malignancy made

TABLE III—DIAGNOSTIC ERRORS OF SURGEON

—	Preoperative	At operation
Number of cases	100	100
No opinion	—	3
Number correct	75	88
Number of errors	25	9
Failure to diagnose malignancy	9	6*
Wrong diagnosis of malignancy	16	3

* In 3 of these the pathologist also was in error on morbid anatomy

TABLE IV—DIAGNOSTIC ERRORS OF PATHOLOGIST

—	Morbid anatomy	Terry section	Frozen section
Number of cases	100	87	89
No opinion	2	1	—
Number correct	92	97	97
Number of errors	6	2	3
Failure to diagnose malignancy	5	1	1
Wrong diagnosis of malignancy	1	1	2

Freehand section stained by Terry's method.—In this technique a freehand section cut with a razor or a safety-razor blade is stained by polychrome methylene-blue In 12% of the cases this technique was not used, because it was thought unnecessary owing to the obvious diagnosis on naked-eye examination It should be remembered, however, that malignant change may be present in association with large simple cysts In 1 other case no section was made, because of technical difficulty, the specimen being a mucoid carcinoma Of the 87 cases examined, in 1 case no opinion was given, and in 2 the diagnosis was wrong in one case a puerperal carcinoma was not diagnosed, because of the predominantly inflammatory picture, and in the other case a large intracanalicular fibroadenoma was misdiagnosed as sarcoma

Frozen section stained with haemalum and eosin —In 10 cases no frozen section was prepared, because it was thought unnecessary owing to the obvious diagnosis on naked-eye examination In 4 of these cases, all cysts, neither Terry examination nor frozen section was considered necessary In 1 other case no section was made, because of the smallness of the specimen and the necessity of conserving tissue for formal paraffin section In the 89 cases examined 3 diagnostic errors were made· 2 of these were identical with the errors made on freehand section stained by Terry's method, in the 3rd, epitheliosis with lipophagic reaction was misdiagnosed as the intraduct carcinoma of Paget's disease

Credits and Debits

Unnecessary mastectomy was avoided in 8 cases in 4 the surgeon had said he would have done a radical mastectomy if immediate examination had not been available, and in the 4 others the intention had been to do a simple mastectomy

In 2 cases unnecessary simple mastectomies were done on the advice of the pathologist in one case for intracanalicular fibroadenoma wrongly thought to be sarcoma, and in the other for epitheliosis misdiagnosed as intraduct carcinoma

In the case of puerperal carcinoma it had already been decided that no further operation was contemplated, and that radiotherapy should be used if the paraffin section showed carcinoma

Time Factors

In 80 cases the time of interruption of the operation averaged 7 minutes On the other hand, the average time spent by the pathologist in 42 cases was 40 minutes In most cases this was accounted for by time spent in waiting for the specimen to be obtained In the other cases the times were not recorded

Conclusions

In 100 consecutive cases of lump in the breast for which immediate histological examination was requested some observations were made Surgical diagnosis of the presence or absence of malignancy was correct in 75% of cases before operation and in 88% at operation Before operation the tendency was to overdiagnose malignancy and at operation to fail to diagnose malignancy The pathologist made the correct diagnosis in 92% of cases on naked-eye examination In 3% of cases the diagnosis reached on Terry section and/or frozen section was incorrect 8 unnecessary mastectomies (4 of which would have been radical) were avoided, but 2 unnecessary simple mastectomies were done despite immediate histological examination It should be emphasised that these examinations were made by ten pathologists as part of their routine duties The results are not claimed to approach those of pathologists who have made a special study of this method

The technique of immediate section does not greatly interrupt the surgeon but is time-consuming (in terms of waiting) for pathologist and technician This is the major economic argument against the method The materials used cost only a few shillings, the bulk of this being the cost of the carbon dioxide used

On balance it seems that immediate histological examination of lumps in the breast is worth while

Summary

100 consecutive cases of immediate histological examination of lumps in the female breast were studied

There is a place for this technique in handling some cases of lump in the breast

I am grateful to my colleagues in the pathology department of the Western Infirmary, Glasgow, for their patience in filling in the relevant questionnaire, and to the surgeons of the Western Infirmary for assisting in this investigation Dr Bernard Lennox compiled the original questionnaire

THYROTOXICOSIS WITH GLYCOSURIA AND ADRENOCORTICAL HYPERACTIVITY

F D Rosenthal

FORMERLY MEDICAL REGISTRAR †

ROYAL INFIRMARY, SHEFFIELD

We have recently seen three men with thyrotoxicosis in whom the excretion of urinary 17-ketogenic steroids was increased Our attention was drawn to the first of these cases because the patient had glycosuria and gynæcomastia The second patient had glycosuria, and when the third presented with glycosuria and gynæcomastia we felt confident that his 17-ketogenic-steroid output would be increased, and this proved to be the case

The exact relation of thyroid to adrenal cortical function has still not been fully determined

In thyrotoxicosis the urinary excretion of 17-ketosteroids has generally been found to be normal or reduced (Engstrom and Mason 1944, Escamilla 1949) Indirect tests of adrenocortical function, such as the eosinophil response to corticotrophin and the insulin-sensitivity test, have been reported to show no abnormality (Hill et al 1950, Hernberg and Lamberg 1955) Levin and Daughaday (1955) found the urinary excretion of 17-hydroxycorticoids to be normal, but they showed that hydrocortisone disappeared from the plasma more rapidly than in healthy subjects

A raised output of urinary 17-ketogenic steroids in thyrotoxicosis appears to be uncommon In an unselected group of eight men and twenty-four women with thyrotoxicosis Levell et al (1957) found the output of urinary 17-ketogenic steroids to be raised in one man and two women (M J Levell, personal communication) In a highly selected group of two men and five women with thyrotoxicosis and diabetes these workers found the urinary 17-ketogenic steroid excretion to be raised in one man and all five women Two of the women were reported in detail by Hubble (1955), the man is case 1 of the present group of cases

The cause of the increased excretion of 17-ketogenic steroids is at present uncertain, and we have carried out studies in our three cases to try and determine its mechanism Our work throws no light on the problem why adrenocortical activity should be increased in some cases of thyrotoxicosis and not in others The findings of M J Levell (personal communication) do not suggest that adrenocortical changes in thyrotoxicosis are more common in one sex than the other, and we feel that the mode of presentation with gynæcomastia in two of our cases has produced a sex bias in this study

Case-records

Case 1 —A miner, aged 41, was seen as an outpatient on April 30, 1956 After a dental extraction 12 months previously he had lost 24 lb (10 5 kg) in weight For 8 months he had felt tired and had little energy He was thirsty, and as a result of an increased fluid intake passed large quantities of urine. He became intolerant of heat and sweated easily For 6 months he had been nervous and tremulous He noticed palpitations, particularly in bed at night, and was short of breath on exercise For 2 months his breasts had been sore. His sister suffered from diabetes mellitus

On examination he was thin, nervous, and sweating, body-weight 129 lb (58 6 kg) Moderate exophthalmos was present The thyroid was moderately enlarged, lobulated, and firm The hands were warm and moist, there was a fine tremor of the outstretched hands Pulse regular, rate 120 per min, blood-pressure 150/70 mm Hg The breasts were slightly enlarged, firm, and tender The nipples were normal, milk could not be expressed The urine gave an orange reaction with Benedict's reagent

Investigations —A radioactive-iodine-tracer test confirmed the diagnosis of thyrotoxicosis, the 4-hour thyroid uptake of iodine was 69 4% of the dose given, and the 48-hour protein-bound iodine 4 36% of the dose given per litre of plasma The 24-hour urinary excretion of 17-ketosteroids was 13 5 mg and of 17-ketogenic steroids 28 8 mg The fasting blood-sugar was 150 mg per 100 ml, 1 hour after the ingestion of 50 g of glucose the blood-sugar was 265 mg per 100 ml, and after 2 hours it was 125 mg per 100 ml Radiographs of the skull and chest were normal The Wassermann reaction was negative The erythrocyte-sedimentation rate (E S R) was 28 mm in the 1st hour (Wintrobe), hæmoglobin 14 0 g per 100 ml

Treatment was with carbimazole 10 mg three times daily by mouth

Admission —He was admitted on Aug 7, 1956, for further studies He was found to be myxœdematous with the typical facial appearance and voice change of this condition The basal metabolic rate was −26% (average of four readings) and the serum-cholesterol 455 mg per 100 ml The 24-hour urinary 17-ketosteroid excretion was 9 1 mg, and that of 17-ketogenic steroids 11 9 mg During the administration of prednisolone 20 mg 6-hourly for 3 days the 24-hour urinary excretion of 17-ketosteroids dropped to 3 9 mg, and the 17-ketogenic-steroid excretion rose to 17 2–25 3 mg The administration of corticotrophin 100 units by intravenous drip daily for 2 days raised the 24-hour urinary excretion of 17-ketosteroids to 34 1 mg and of 17-ketogenic steroids to 87 8 mg The fasting blood-sugar was 105 mg per 100 ml, following the ingestion of 50 mg of glucose the blood-sugar was 224 mg per 100 ml after 1 hour, and 156 mg per 100 ml after 2 hours The patient was discharged on Aug 19, 1956

Second admission —He was readmitted on Oct. 12, 1956, having had no antithyroid treatment in the meantime He was thyrotoxic, the basal metabolic rate was +40% (average of four readings) and the serum-cholesterol 230 mg per 100 ml

---

* Present address Department of Neurology, Queen Elizabeth Hospital, Birmingham, 15

† Present address Department of Neurology, Royal Infirmary, Manchester, 13

The 24-hour urinary 17-ketosteroid excretion was 14·8 mg, that of 17-ketogenic steroids 31·6 mg. Following the administration of prednisolone 20 mg 6-hourly for 3 days the 24-hour urinary excretion of 17-ketosteroids was 11·5 mg and of 17-ketogenic steroids 10·1 mg. The administration of corticotrophin 100 units by intravenous drip daily for 2 days increased the 24-hour urinary excretion of 17-ketosteroids to 14·7 mg and of 17-ketogenic steroids to 45·8 mg. The fasting blood-sugar was 84 mg per 100 ml, following the ingestion of 50 g of glucose the blood-sugar level was 216 mg per 100 ml after 1 hour, and 105 mg per 100 ml after 2 hours. A further glucose-tolerance curve showed the fasting blood-sugar to be 90 mg per 100 ml, following ingestion of 50 g of glucose the blood-sugar was 264 mg per 100 ml after 1 hour, 156 mg per 100 ml after 2 hours, and 120 mg per 100 ml after 2½ hours.

Progress.—The patient was discharged on Oct 27, 1956, and the thyrotoxicosis has since been controlled by carbimazole 10 mg three times daily. His gynæcomastia has disappeared.

Case 2.—A car deliverer, aged 55, was seen as an outpatient on Dec 24, 1956. He had not been well for about 10 months, during which time he had lost 35 lb (16 kg) in weight. For 9 months he had sweated easily, had been trembly, disliked warm weather, and suffered palpitations with shortness of breath on exercise. For 3 months his eyes had been prominent and occasionally he saw double. He had become nervous and depressed.

On examination he was thin, nervous, and sweating, body-weight 142 lb (64·5 kg). Both eyes, especially the right, were prominent and both eyelids were œdematous. The thyroid was only just palpable, it was smooth and firm. The hands were warm and moist with a fine tremor. He had auricular fibrillation with heart-rate of 116 per min, blood-pressure 140/70 mm Hg. The urine gave a yellow reaction with Benedict's reagent.

Investigations.—A radioactive-iodine-tracer test confirmed the diagnosis of thyrotoxicosis, the 4-hour thyroid uptake of iodine was 67·5% of the dose given, and the 48-hour protein-bound iodine 1·23% of the dose given per litre of plasma. The 24-hour urinary excretion of 17-ketosteroids was 10·6 mg, of 17-ketogenic steroids was 24·8 mg, and of gonadotrophins 8 mouse units. The fasting blood-sugar was 110 mg per 100 ml, following the ingestion of 50 g of glucose the blood-sugar level was 160 mg per 100 ml after 1 hour, and 79 mg per 100 ml after 2 hours. Radiographs of the skull and chest were normal. An electrocardiogram confirmed the presence of auricular fibrillation. The Wassermann reaction was negative. The E S R was 11 mm in the 1st hour (Wintrobe), the hæmoglobin was 13·2 g per 100 ml.

Admission.—The patient was admitted on Jan 15, 1957, for further studies. The basal metabolic rate was −28% (average of four readings) and the serum-cholesterol 245 mg per 100 ml. The 24-hour urinary excretion of 17-ketosteroids was 8·7 mg, of 17 ketogenic steroids 36·5 mg, and of gonadotrophins 5 mouse units. During the administration of prednisolone 20 mg 6-hourly for 3 days the 24-hour urinary excretion of 17-ketosteroids fell to 5·8 mg, and that of 17-ketogenic steroids varied between 23·2 and 42·5 mg. During the administration of corticotrophin gel 20 mg 12-hourly intramuscularly for 2 days the urinary 24-hour excretion of 17-ketosteroids was 9·5 mg and 13·3 mg, and that of 17-ketogenic steroids was 40·5 mg and 47·7 mg. The fasting blood-sugar was 70 mg per 100 ml, following the ingestion of 50 g of glucose the blood-sugar was 204 mg per 100 ml after 1 hour, and 108 mg per 100 ml after 2 hours.

Progress.—The patient was discharged on Feb 5, 1957, and since then his thyrotoxicosis has been controlled by carbimazole. When he was seen as an outpatient on Nov 18, 1957, his auricular fibrillation had ceased and his pulse-rate was 80 per min. He appeared euthyroid and the serum-cholesterol was 250 mg per 100 ml. The 24-hour urinary excretion of 17-ketosteroids was 10·0 mg and of 17-ketogenic steroids 15·4 mg. The fasting blood-sugar level was 100 mg per 100 ml, following the ingestion of 50 g of glucose the blood-sugar was 150 mg per 100 ml after 1 hour, and 60 mg per 100 ml after 2½ hours.

Case 3.—A telephone engineer, aged 48, was seen as an outpatient on Sept 12, 1957. He had not felt well for about 9 months during which time he had lost about 14 lb (6·5 kg) in weight. He sweated a great deal and had become intolerant of warm weather. He felt nervous and trembly, on exercise he was short of breath and had palpitations. He had started to be thirsty, and as a result of the increased fluid intake passed large quantities of urine. For 2 months his breasts had been tender and painful, so that he had to give up wearing braces.

On examination he was nervous and sweating, body-weight 139 lb (63 kg). The eyes were prominent and the eyelids œdematous. The thyroid was impalpable. There was fine tremor of the outstretched hands. The pulse was regular, rate 108 per min, blood-pressure 130/70 mm Hg. The breasts were slightly enlarged, uniformly firm, and tender, the nipples were normal, milk could not be expressed. The urine gave a yellow reaction with Benedict's reagent.

Investigations.—A radioactive-iodine-tracer test confirmed the diagnosis of thyrotoxicosis, the 4-hour thyroid uptake of iodine was 79·8% of the dose given, and the 48-hour protein-bound iodine was 2·34% of the dose given per litre of plasma. The 24-hour urinary excretion of 17-ketosteroids was 15·4 mg and 11·1 mg, of 17-ketogenic steroids 23·7 mg and 27·2 mg, and of gonadotrophins 25 mouse units. The fasting blood-sugar was 83 mg per 100 ml, following the ingestion of 50 g of glucose the blood-sugar was 160 mg per 100 ml after ½ hour, 140 mg per 100 ml after 1 hour, and 75 mg per 100 ml after 2 hours. The serum-cholesterol was 140 mg per 100 ml. Radiographs of the skull and chest were normal. The Wassermann reaction was negative. The E S R was 15 mm in the 1st hour (Wintrobe), the hæmoglobin was 14·2 g per 100 ml.

Treatment and progress.—The patient was treated with carbimazole 10 mg three times daily by mouth, and when seen as an outpatient on Jan 9, 1958, he appeared euthyroid. The gynæcomastia had disappeared. The serum-cholesterol was 280 mg per 100 ml. The 24-hour urinary excretion of 17-ketosteroids was 8·6 mg and of 17-ketogenic steroids 8·2 mg. The fasting blood-sugar was 73 mg per 100 ml, following the ingestion of 50 g of glucose the blood-sugar was 120 mg per 100 ml after 1 hour, and 55 mg per 100 ml after 2 hours.

Discussion

Thyrotoxicosis with exophthalmos is generally regarded as pituitary in origin (Naffziger 1954). In our three cases in addition to a state of thyroid stimulation there was increased excretion of adrenocortical hormones—which suggested that adrenocortical stimulation was also present. In the study of his two cases of thyrotoxicosis with diabetes mellitus and adrenocortical hyperactivity, Hubble (1955) thought that panhyperpituitarism was the primary abnormality. One of the most striking features of our cases was that when a euthyroid or myxœdematous state was reached adrenocortical hyperactivity ceased. This suggested that the thyrotoxicosis itself was the cause of the adrenocortical overaction. Hubble (1955) in one of his cases also found that the adrenocortical hyperactivity decreased once the thyrotoxicosis was under control.

In thyrotoxicosis uncomplicated by diabetes the fasting blood-sugar is normal, but the renal threshold is commonly lowered and rapid absorption of glucose may raise the blood-sugar sufficiently to produce glycosuria (John 1932, Spence 1953). This appeared to be the cause of the glycosuria in the present case 3, and his oral glucose-tolerance curve became normal once the thyrotoxicosis was controlled It was probably also the cause of the glycosuria in case 2, but it was difficult to explain the first fasting blood-sugar of 110 mg per 100 ml and also the fasting blood-sugar of 100 mg per 100 ml once he was euthyroid In patients who have recovered from thyrotoxicosis the incidence of diabetes is greater than in the general population (John 1932) This is unlikely to be of adrenocortical origin as steroid diabetes has been reported to be nearly always reversible once adrenocortical hyperactivity ceases (Frawley 1955) Houssay (1944) has shown that prolonged administration of thyroid extract to normal dogs has no permanent effect on glucose tolerance, but that in non-diabetic partially depancreatised dogs irreversible diabetes frequently results Case 1 as well as case 1 of Hubble (1955) had a family history of diabetes, and the failure of their diabetes to improve once the thyrotoxicosis was controlled may have been due to their being potential diabetics before the onset of thyrotoxicosis

Gynæcomastia in thyrotoxicosis was already known to von Basedow (1848) and more recently has been observed by Sterling (1932), Starr (1935), and Ballinger (1947) One of the cases of Starr (1935) had testicular atrophy, and the case of Ballinger (1947) had undescended testes, but their gynæcomastia only developed with the onset of thyrotoxicosis The gynæcomastia in these two cases, as in the second case of Starr (1935), disappeared following thyroidectomy Gynæcomastia appeared in the present cases 1 and 3 as the symptoms of thyrotoxicosis became prominent, it regressed when the patients became euthyroid on carbimazole Gynæcomastia cannot be regarded as indicating hyperpituitarism and may occur in many endocrine and non-endocrine conditions (Menville 1933, Spence 1953) It can be of purely adrenal origin and has been observed after administration of adrenocortical extracts and deoxycortone (Edwards et al 1938, Laurence 1943)

In our cases there were no features suggesting acromegaly, and estimation of the urinary gonadotrophins in cases 2 and 3 showed their excretion to be within normal limits In our three cases and in the two cases reported by Hubble (1955) only the excretion of urinary 17-ketogenic steroids was increased and the urinary 17-ketosteroids were normal These results suggested hypertrophy of the zona fasiculata, the main secretor organ of glucocorticoids, and a normal zona reticulata, which produces androgens (Landing 1955) Such findings were in agreement with those of Deane and Greep (1947), who in thyrotoxic dogs found the zona fasiculata hypertrophied and overactive, but the zona reticulata unaffected The increased output of 17-ketogenic steroids in our patients was unaccompanied by the usual signs of glucocorticoid overproduction and moon-face, hypertension and polycythæmia were not seen This combination of increased glucocorticoid excretion without the signs of Cushing's syndrome has been shown by Ingle (1952) to characterise the response to stress by the adrenal cortex Such conditions have been observed after surgery and have occasionally been seen in cases of cancer (Hardy et al 1953, Hardy 1953, Jepson et al 1956)

The mechanism of the adrenocortical hyperactivity does not appear to us to be of primary pituitary or of primary adrenal origin, as control of the thyrotoxicosis resulted in normal adrenocortical function This result was achieved by carbimazole, which has no direct action on the pituitary or adrenal It seems clear that the thyroid overactivity acting through the pituitary or the adrenal cortex may have been the fundamental cause of the overactive adrenal cortex This appeared to be the most important result of our investigations It is strongly supported by the work of Deane and Greep (1947), who showed that the administration of thyroid extract to thyroidectomised dogs rendering them thyrotoxic produced hypertrophy and hyperactivity of the zona fasiculata and the zona glomerulosa It seems to us most likely that the effect of the thyrotoxicosis is on the pituitary, being comparable with reactions to other systemic diseases which have been described as inducing an increased output of corticotrophin (Currie and Symington 1955)

Summary

Three cases of men with thyrotoxicosis, in whom a high urinary excretion of 17-ketogenic steroids indicated adrenocortical hyperactivity, are described

All three patients had glycosuria, and two had gynæcomastia

On treatment with carbimazole the patients became euthyroid or myxœdematous, adrenocortical hyperactivity ceased, and the gynæcomastia disappeared

There were no signs of acromegaly or of Cushing's syndrome, and the urinary excretion of gonadotrophins was normal in the two cases where they were estimated

Apparently the primary cause of the increased adrenocortical activity was the thyrotoxicosis, and the adrenocortical hyperactivity was not primarily pituitary or adrenal in origin

We wish to thank Dr H P Brody, under whose care these patients were admitted, for his encouragement, and Mr M J Levell for the steroid estimations

" On the humanitarian view all crime is pathological, it demands not retributive punishment but cure This separates the criminal's treatment from the concepts of justice and desert, a 'just cure' is meaningless On the old view public opinion might protest against a punishment (it protested against our old penal code) as excessive, more than the man 'deserved', an ethical question on which anyone might have an opinion But a remedial treatment can be judged only by the probability of its success, a technical question on which only experts can speak Thus the criminal ceases to be a person, a subject of rights and duties, and becomes merely an object on which society can work And this is, in principle, how Hitler treated the Jews They were objects, killed not for ill desert but because, on his theories, they were a disease in society If society can mend, remake, and unmake men at its pleasure, its pleasure may, of course, be humane or homicidal The difference is important But either way, rulers have become owners "—Prof C S Lewis, *Observer,* July 20, 1958

VAGOTOMY IN HYPERTROPHIC PULMONARY OSTEOARTHROPATHY ASSOCIATED WITH BRONCHIAL CARCINOMA

MIDDLESEX HOSPITAL, LONDON, W 1

Since Hippocrates first described clubbing of the fingers and toes in the 5th century B C there have been numerous descriptions of the condition, including an important publication by Mendlowitz (1942) Some of the underlying pathological causes include pulmonary and cardiac conditions, ulcerative colitis, steatorrhœa, cirrhosis of the liver, roundworm infestation, and, rarely, thyroidectomy (Mendlowitz 1942)

In some cases finger clubbing may be associated with incapacitating hypertrophic osteoarthropathy

The most common cause of severe osteoarthropathy is bronchial carcinoma The proportion of bronchial carcinoma reported as showing painful osteoarthropathy varies from 1–2% (Semple and McCluskie 1955) and 5–10% (Flavell 1956) up to 50% (Alvarez 1948) The incidence is probably well under 5% It is peripheral carcinoma rather than the central tumour which is more commonly associated with osteoarthropathy The peripheral type is a relatively uncommon form of lung carcinoma, and is often a localised lesion involving neither pleura nor hilum It is usually surprisingly small in view of the severity of the symptoms in the limbs

Often a quite astonishing improvement takes place after pneumonectomy or even after local removal of the tumour There is often complete loss of pain within a few hours and the effusions in the joints may improve after a few days The clubbing of the fingers and toes sometimes progressively improves, the nails returning to normal as the nail grows out (Flavell 1956)

The satisfactory results of resection in man are also seen in the dog (Lumb and Carlson 1956) Simple operations have had an equally satisfactory effect on pulmonary osteoarthropathy—e g , ligation of the pulmonary artery on the side of the lesion (Wyburn-Mason 1948) and denervation of the lung hilum in inoperable carcinoma (Brea 1948, Hansen 1954) In these operations division of the nerve-supply was apparently the deciding factor in relieving the joint symptoms, rather than any direct interference with the tumour Following these observations and his own previous results of attempted removal, Flavell (1956) denervated the hilum in two cases of inoperable carcinoma with equally satisfactory results The effect was then tried, in three cases, of simple division of the vagus immediately above the hilum without disturbing the hilar structures, the pulmonary osteoarthropathy in all three cases subsided immediately

In view of the remarkable palliation observed by Flavell, vagotomy was done in two advanced cases of unresectable pulmonary carcinoma with severe osteoarthropathy In one case the osteoarthropathy was so incapacitating, with both hands and feet extremely painful and swollen, that the patient was completely crippled

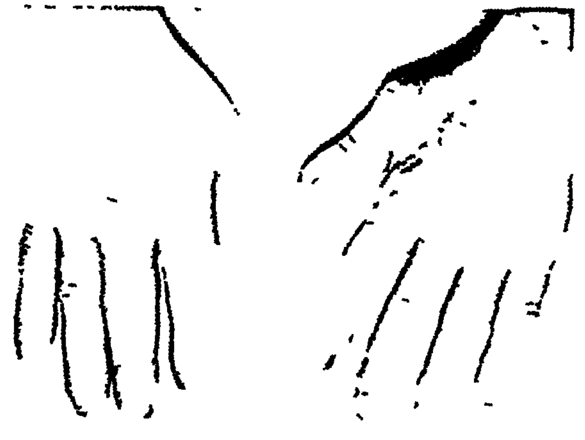

Fig 1—Case 1 œdema of hands and clubbing of fingers

Case-reports

Case 1—A man, aged 64, was admitted to hospital in May, 1956, with advanced pulmonary osteoarthropathy Severe pain limited the movements of his hands, elbows, feet, and knees He was bedridden The symptoms had started in March, 1956, a week after an attack of pneumonia He had been a coalminer many years previously and had been a heavy smoker

On examination his general condition was poor His hands were swollen with œdema and showed severe clubbing (fig 1) Pain was particularly severe in his right hand, wrist and, elbow He had massive œdema of his ankles and feet with extreme tenderness Air entry was diminished over his left upper lobe, and numerous rhonchi were heard over his left lung He was dyspnœic on the slightest exertion and had marked bilateral gynæcomastia There were no other relevant findings

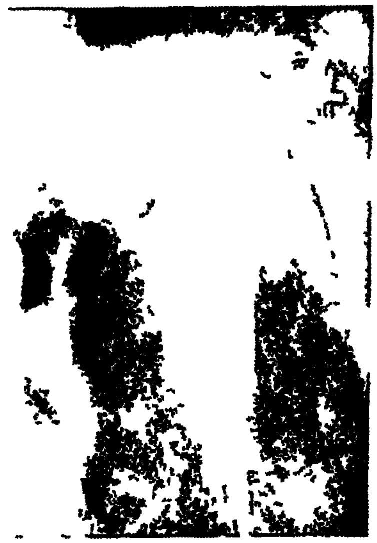

Fig 2—Case 1 tomograph showing rounded mass in upper lobe of left lung

Radiography of his chest showed a peripheral rounded opacity in the upper lobe of the left lung Tomography showed that this opacity was homogeneous and had rather ill-defined margins, suggesting a bronchial carcinoma (fig 2)

Bronchoscopy showed no abnormality Severe bronchitis contra-indicated resection

Treatment—Three days after admission, deep X-ray therapy was begun and a tumour dose of 3485r was given over thirty days In spite of this there was no improvement in the severe pain of the osteoarthropathy, the dyspnœa was not alleviated, and the patient remained completely bedridden Although his very poor condition made him a grave operative risk, it was thought justifiable to try the effect of vagotomy, without attempting to remove the tumour

Operation—A left lateral thoracotomy was done in June, 1956, by Mr J R Belcher The vagus nerve was identified and divided beneath the arch of the aorta immediately below the point where the recurrent laryngeal nerve was given off No other structures were disturbed

Postoperative course—Within twenty-four hours all the pains in the bones and joints were relieved, the swelling and œdema of the hands and feet were regressing, and the movements of the hands and fingers had much improved In three days the œdema had completely disappeared, the dyspnœa was considerably improved, and the patient got up At the end of ten days he was walking round the ward pain-free

Discharge and follow-up.—He was discharged from hospital on the thirteenth postoperative day On the twenty-fifth postoperative day he walked into the outpatients clinic without any pain, œdema, or gynæcomastia He was last seen nine months later, when he complained of considerable loss of weight and vomiting His general condition was deteriorating, and his liver was grossly enlarged, but he still had no pain or œdema, although the clubbing was still present He was not dyspnœic and had no gynæcomastia

Case 2.—A man, aged 57, was admitted in August, 1956, complaining of feeling unwell and of having lost weight since an attack of "influenza" in February Since May, 1956, he had noticed clubbing of his fingers and toes and had increasing painful swelling of his ankles and knees Mild dyspnœa had been present for the same period He had smoked heavily for forty years

On examination he had marked clubbing of his fingers and toes and swelling of his ankles and knees Movement of these joints was painful and limited

Radiography of his chest showed a large rounded mass in the right mid-zone, extending outwards to the chest wall in the axilla (fig 3)

Bronchoscopy showed a submucous infiltration of the lateral wall of the right main bronchus, and biopsy of this area disclosed a poorly differentiated carcinoma

Operation.—A right thoracotomy was done in August, 1956 by Mr J W Jackson A growth was found in the right upper lobe, extending across the oblique fissure but not adherent to the parietal pleura Large lymph-nodes involved by carcinoma in the hilum made the growth inoperable The vagus nerve was therefore identified above the hilum and divided

Postoperatively the relief of pain was immediate and the œdema disappeared within forty-eight hours On the thirteenth postoperative day a course of deep X-ray therapy to the primary tumour and to bilateral supraclavicular glands which had appeared since the operation, was begun A tumour dose of 2834r was given over three weeks The patient was discharged from hospital on Sept 24, 1956

Follow-up.—In January, 1957, he had a second palliative course of deep X-ray therapy to secondary deposits in his pelvic bones, ribs, and cervical lymph-nodes Despite progression of his metastases he had no further symptoms from his pulmonary osteroarthropathy There was no change in the degree of clubbing His general condition continued to deteriorate, and he died in March, 1957

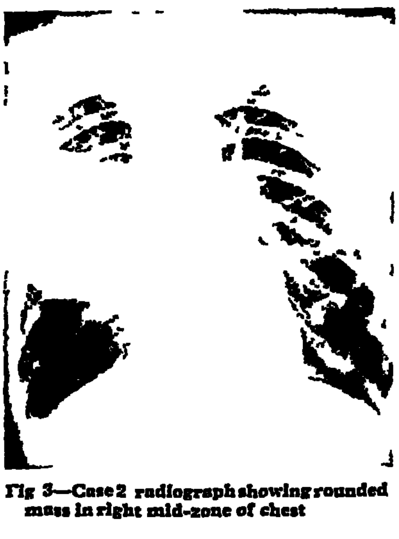

Fig 3—Case 2 radiograph showing rounded mass in right mid-zone of chest

Discussion

Both patients had severe pulmonary osteoarthropathy, of which pain was the prominent symptom This pain completely overshadowed the pulmonary symptoms of carcinoma

The rapid and complete relief of pain in the joints, followed by resolution of the swelling and œdema, confirm the finding of Flavell (1956) An unusual feature was the bilateral gynæcomastia in case 1, which regressed after vagotomy The association of gynæcomastia with carcinoma of the bronchus has been noted previously, Stephens (1928) reported an incidence of 7%, and Semple and McCluskie (1955) of 8 3% No case has hitherto been reported which had been successfully treated by vagotomy

Although the causation of osteoarthropathy is unknown, the nervous theory of Cudkowicz and Armstrong (1953) appears to be the soundest They postulate a pulmonary autonomic systemic vascular reflex by which ischæmia in parts of the lung distal to the tumour reflexly cause systemic arteriovenous anastomoses to open up in the limbs

In the present two cases the following points support the theory that hypertrophic pulmonary osteoarthropathy is primarily due to a nervous and not a chemical mechanism

(1) If osteoarthropathy were caused by a chemical substance liberated by the tumour, one would expect that the most severe manifestations would be associated with tumours with extensive secondary deposits Local removal of a small tumour, however, may give remarkable and usually permanent relief from osteoarthropathy It is uncommon for pain and swelling to occur after resection, even though extensive metastases develop later

(2) The associated gynæcomastia could be explained by the pulmonary autonomic systemic vascular reflex theory, arteriovenous anastomoses opening up in the breast as in the limbs

(3) Many lesions, totally different in ætiology and pathology, produce the manifestations of hypertrophic pulmonary osteoarthropathy A common autonomic pathway could be postulated for most of these, but would meet with many difficulties by a chemical or a hormonal explanation In the present cases simple division of the vagus produced relief of the pain and resolution of the œdema, although the pulmonary lesion was undisturbed (It might be objected that the deep X-ray therapy to the primary lesion might have had an effect, but this is extremely unlikely because in case 2 the beneficial effects of the vagotomy were clear before the X-ray therapy was started)

The complete relief of the pain and the disappearance of the œdema, despite the progression of the disease and the persistence of clubbing, appear, from the follow-up in these cases, to be permanent

Many patients with hypertrophic pulmonary osteoarthropathy associated with an inoperable carcinoma of the bronchus might receive much benefit from vagotomy (which might be done through a thoracoscope)

Probably all patients undergoing thoracotomy for inoperable carcinoma of the bronchus, should also undergo routine vagotomy on the side of the lesion, irrespective of whether they have osteoarthropathy at the time or not

In this way patients who have, or may have, one of the most painful manifestations of carcinoma of the bronchus may be saved a great deal of pain and discomfort and will therefore be able to spend several months of active life

Summary

Two patients with inoperable pulmonary carcinoma and severe hypertrophic pulmonary osteoarthropathy treated by vagotomy obtained immediate complete relief of disabling pain Associated œdema and, in one case, gynæcomastia also disappeared

The possible mechanism of hypertrophic pulmonary osteoarthropathy is discussed, and a nervous reflex is favoured

Despite the fact that this condition is rare, patients who undergo thoracotomy for an unresectable carcinoma of

the bronchus should have a vagotomy on the side of the lesion done as a routine In inoperable cases with hypertrophic pulmonary osteoarthropathy this should be done where possible By this relatively minor operation these patients will not only be saved much pain and misery but will also possibly live many months of active life

We are grateful to Prof B W Windeyer, Mr T Holmes Sellors, Miss M D Snelling, Mr J R Belcher, and Dr A M Jelliffe for permission to publish these cases, and we wish to thank Mr M. Turney and the staff of the photographic department of the Middlesex Hospital for their invaluable help with the illustrations

PENICILLIN SENSITIVITY IN PATIENTS WITH BURNS

MARY R DAVIES
M.B Edin.

RESEARCH REGISTRAR, MEDICAL RESEARCH COUNCIL
BURNS RESEARCH UNIT, BIRMINGHAM ACCIDENT HOSPITAL

WITHIN recent years there have been a number of deaths from penicillin therapy (Wilensky 1946, Waldbott 1949 *British Medical Journal* 1951, Thompson 1952, Harpman 1952, Kern and Wimberley 1953, Feinberg and Feinberg 1956) and an increase in sensitivity reactions (*Lancet* 1957) The reported incidence has varied from 1 2% (Lepper et al 1949) to 60 5% (Cormia et al 1945), but 5–6% seems to be the usual reaction-rate following intramuscular injection (Mayer et al 1953, Feinberg and Feinberg 1956) Detailed reports of reactions following local application of penicillin are few, but Kern and Wimberley (1953) stated that it leads to sensitivity more commonly than any other mode of administration, and figures of 10–20% have been cited (Templeton et al 1947) By contrast, Collier (1958) found no sensitivity reactions in about 11,000 minor burns and wounds treated with penicillin ointment.

Penicillin cream has been used as the routine treatment for burns at the Birmingham Accident Hospital since 1945 It was introduced as a result of the observation in Glasgow that penicillin cream was efficacious against hæmolytic streptococcal infection of burns (Clark et al 1943), and it has been proved to have considerable prophylactic value against the same organism (Jackson et al 1951)

In the past, sensitivity reactions to local penicillin in this unit have been few and transient (Bull et al 1954), but, in view of the reported increasing incidence of sensitivity reactions, the risks involved in the continued use of local penicillin have been freshly assessed

Method

All patients were reviewed who attended the burns unit for the first time between Jan 1 and June 30, 1957 The clinical staff were informed of the intended survey and recorded any possible allergic reaction The use of 1% cetrimide as a cleansing agent was discontinued for the period of the review, since it can also cause sensitivity

Penicillin cream was made in the following base

Ol ricini	28%
'Lanette Wax S.X.'	14%
Glycerin	10%
Aqu. ad	100

TABLE I—FORMS OF PENICILLIN TREATMENT

Form	Inpatients	Outpatients	Total
Cream	82	1046	1128
Powder	49	266	315
Spray	25	10	35
Jelly	0	8	8
Eye ointment	1	1	2
Oral	7	6	13
Intramuscular	15	26	41
No receiving more than one form	59	197	256
Total	120	1166	1286

The usual concentration of penicillin was 1000 units per g, but some patients had 10,000 units per g for treatment of streptococcal infection Penicillin powder was made up in a lactose powder base (10,000 units per g)

1419 new patients attended during the six-month period. Of these, 1260 were outpatients, 135 were inpatients, and 24 were treated initially as outpatients and were admitted later This last group has been included with the outpatients, since most of the penicillin cream was applied before admission 436 outpatients (34%) and 68 inpatients (50%) were under 14 years of age.

1286 patients received penicillin during treatment, most of them having it locally (table I)

Results

Reactions

No anaphylactic reaction occurred In 35 cases a rash developed In some patients this was obviously due to a cause other than penicillin (for example, measles), but in 10 patients it was considered on clinical grounds that the rash might be a penicillin sensitivity reaction (table II) Other possible sensitising agents had been given to four of these patients—namely, plasma (3), blood (1), streptomycin (1), and a jelly of unknown composition (1) 4 of the reactions followed the systemic administration of penicillin (3 intramuscularly, 1 orally) combined with local therapy. In the majority the rash occurred twelve to sixteen days after burning, in 3 it occurred on the fourth to fifth days, and in the remaining patient on the twenty-second day a few hours after the first injection of penicillin No rash lasted longer than four days, and in the majority it subsided within forty-eight hours 6 of the 10 patients had penicillin cream applied again, three days to six months later, with no reaction

Only 1 patient had any systemic upset accompanying the rash

This patient sustained an 8% burn of face and hands The hands were dressed with penicillin cream and the face was treated by exposure with penicillin powder The dressings were changed on days 1, 4, 11, and 14 On the evening of day 14 an urticarial rash developed on the legs and trunk. The patient was given mepyramine 100 mg t.d s, and calamine lotion was applied locally The following day the rash continued, she complained of abdominal pain and vomited twice On day 16 the dressing was changed to tulle-gras, and the rash faded. Skin-grafting was carried out on day 19 and tulle-gras dressings were continued. On day 31, group-A hæmolytic streptococci were found on the hands, which were then dressed with penicillin cream 10,000 units per g This dressing was repeated on days 32, 34, 36, 37, 39, and 40 There was no reaction to these later applications

2 other patients had a definite allergic reaction, but as neither had received penicillin in any form the reaction could not be attributed to this cause

If the rashes have been correctly attributed, then the total incidence of penicillin reactions was 0 8% (10 out of 1286) The incidence in inpatients was higher (3 3%) than in outpatients (0 5%) Although this could be due to more extensive application of the cream, it seems more

TABLE II—RASHES IN 1419 PATIENTS

Type of reaction	Inpatients	Outpatients	Cause to which rash attributed				No penicillin before rash	"Penicillin" rash, no reaction to later penicillin
			Penicillin	Infection	Irritation	Other		
Urticarial with systemic upset	1	0	1					1
Urticarial only	3	1	4					3
Measles	4	0		4				
Chickenpox	1	0		1				
Scarlatinaform with hæmolytic streptococcal infection	2	1		3			1	
Generalised erythematous (other than above)	2	5	4	1		2*	2	2
Localised	3	12	1	4	10		2	
Total	16	19	10	13	10	2	5	6

* 1, tulle-gras, 1, blood-transfusion

likely to be the effect of a larger number receiving systemic therapy The overall incidence of reactions in those receiving local application only was 0 5% (6 out of 1232), and in those having systemic therapy, usually combined with local, 7 4% (4 out of 54)

Since a number of outpatients had minor burns and did not attend hospital more than once or twice, these figures may be falsely low 203 outpatients receiving penicillin were transferred, or did not attend more than twice If, for this reason, these patients are excluded, then the total incidence of reactions was 0 9% (10 out of 1083), in outpatients 0 6% (6 out of 963), from local application only 0 6% (6 out of 1030), from combined systemic and local administration 7 6% (4 out of 53)

History of Previous Sensitivity

14 outpatients (1 1%) and 3 inpatients (2 2%) gave a history of allergy to penicillin 7 of these had penicillin cream applied during treatment, and none had a reaction

One patient with a history of penicillin sensitivity had a reaction

This patient had penicillin injections on account of a septic finger in 1955 Eighteen months later (December, 1956) he sustained a 1 5% burn of the forearm, which was treated with penicillin powder and boracic fomentations at work When he was referred here two weeks after injury, the area was rather swollen Penicillin cream was applied, and three days later he had a sensitivity reaction The dressing was changed to tulle-gras, but he returned the following day with the arm more swollen and painful, and a vesicular eruption over the whole burned area The reaction gradually subsided with local calamine lotion and systemic antazoline In June, 1957, he sustained a small burn of the opposite forearm This was dressed with tulle-gras, and two days later he returned with swelling of the forearm and a vesicular rash over the area covered with tulle-gras The rash and burn healed in two weeks It is apparent that this patient was sensitive to tulle-gras which he had on both occasions, as well as to penicillin

Discussion

In assessing the incidence of penicillin sensitivity, the first difficulty is correct diagnosis Where patients are exposed to several possible sensitising agents, this may be extremely difficult Skin tests are generally considered to be unreliable (Farmer 1953, Tuft et al 1955, Feinberg and Feinberg 1956) and penicillin sensitivity may be lost spontaneously (Matthews et al 1956) 6 of our patients with "penicillin sensitivity" had no reaction to repeat applications within six months, either they must have lost their sensitivity very rapidly, or the reaction was wrongly attributed to penicillin Similarly, of the 17 patients who gave a history of previous allergy, 7 were exposed to the drug with no reaction

None of the reactions in these patients endangered life, nor are we aware of any serious reaction during the thirteen years the drug has been used routinely here Most of the reactions were mild and transient, and some would not have been noted had the review not been in progress Only a few patients had any appreciable discomfort from the reaction

Comparing the incidence of reactions in this series with other published results, the reaction-rate after systemic administration (7 4%) is of a similar order to that found by other workers (Lyons 1943, 5 7%, Mayer et al 1953, 6%, Vickers et al 1958, 5%) Our incidence after local application only (0 5%) is much lower than other reported figures Reports of reaction to local therapy have usually been on patients with dermatitis, who are probably particularly susceptible (Kolodny and Denhoff 1946) The present results, in patients without skin disease, show a very low reaction-rate to local application of penicillin, and much lower than to systemic administration

The necessity of incurring even this small risk may reasonably be questioned, and there would be no justification if there was another agent which was as effective and safer Local penicillin cream is at present the best prophylactic agent against colonisation with *Streptococcus pyogenes*, which so frequently causes graft failure In a controlled trial of cases of burns, *Str pyogenes* infection developed in only 3 7% of cases treated with penicillin cream, compared with 47 4% in a control group (Jackson et al 1951) In view of its obvious advantages and the low incidence of reactions penicillin cream can justifiably be applied prophylactically

Summary

1419 patients with burns were observed for evidence of any sensitivity reaction

0 5% (6 out of 1232) of patients receiving local penicillin had a reaction possibly attributable to penicillin, compared with 7 4% (4 out of 54) of patients receiving systemic penicillin Most of the reactions were mild, and none lasted longer than four days

Accurate diagnosis is often difficult, and the sensitive state may be transient, as is illustrated by the fact that 6 of the 10 patients with "penicillin sensitivity" had no reaction to subsequent local application of the drug

OTOLOGIST

MAIDA VALE HOSPITAL FOR NERVOUS DISEASES, LONDON, W 9

DISTURBANCES of balance resulting from vestibular disorders have long been known to lead to severe anxiety (Gowers 1893, Cawthorne 1957) The recent finer analysis of affections of the eighth nerve, in particular by Hallpike and his colleagues (Cawthorne et al 1956, Carmichael et al 1956), has led to improved diagnosis of these patients The factor of positional nystagmus of the benign paroxysmal type in causing some of the symptoms of the post-traumatic state has been emphasised (Gordon 1954, Harrison 1956), together with the importance of differentiating these symptoms from those of psychological origin Less attention has been paid to the mental features displayed by patients with disturbances of balance

On the other hand, complaints of disturbance of balance are a classical feature of hysteria and anxiety states (Mayer-Gross et al 1954) and are then generally accepted as being without organic basis We review here 12 cases (see table) in which anxiety states followed directly on disturbance of balance and the symptoms attributable to anxiety predominated The prognosis of these anxiety states appeared to depend on the recognition and treatment of the primary disturbance.

Illustrative Case-reports

Case 1 —A clerk and housewife, aged 24, developed attacks of unsteadiness, feeling " as if mildly drunk " and as if she had just been subjected to rotation, brief initially but later more persistent, and increasingly accompanied by panic attacks, depression, fears of dying, and a feeling of vibration in the head with preoccupation about her symptoms (She had no rotatory vertigo until six months after the onset.) She had previously been free from neurotic symptoms, apart from a tendency to worry When seen five weeks after the onset caloric responses were minimal No diagnosis, however, could be made by otological examination. She improved slowly at first with sedation and reassurance, and more rapidly when she was instructed in a range of balancing exercises seven weeks after the onset She returned to work six weeks later, and her symptoms continued to improve When seen six months after the onset her caloric responses showed no change, she reported that this test led to rotatory vertigo followed by her non-rotatory unsteadiness A year after the onset she had been symptom-free for five months

Case 3.—A male factory worker, aged 43, had had occasional attacks of vertigo lasting up to five minutes since the age of 12 years He had rotatory vertigo if the attacks came on when he was lying down, but in the erect position his surroundings seemed to tip to the right Of late he had become increasingly fearful of an attack, was never at ease sitting in a cinema even when at the back in the end seat, and felt particularly tense in the barber's chair In addition, apart from his attacks, for a month or so he would feel that he must walk on the left side of the pavement, and used to sweat if he had to walk on the right side He was adopted, had an unhappy childhood, walked once in his sleep, wet the bed until the age of 6 years, and occasionally stammered when flustered His caloric responses were normal but reproduced the sensation of vertigo No otological diagnosis was made He had not improved on anticonvulsants, but improved promptly when he was instructed in a range of balancing exercises His attacks of vertigo became somewhat less frequent, his feelings of anxiety vanished, and he reported that he was still well in this respect a year later

Case 12 —A housewife and hairdresser, aged 38, reported that, nine months previously, after a period of overwork, she developed a muzzy feeling with continuous headaches and depression, and three months later spent three weeks in bed feeling exhausted, during this time she had a continuous feeling that she was falling through the bed. She had previously been free from neurotic symptoms She continued to be depressed and to have dizziness and nausea, and did not improved with sedation and superficial psychotherapy Seven months after her first attendance she reported an attack in which her surroundings went round and round and she staggered, she then recalled that she had had this sensation fifteen months before her first attendance and earlier than that for very brief periods On otological examination her caloric responses were normal, apart from a minimal response to water at 44°C in the right ear, but she reported that the sensation she had experienced during irrigation was similar to her spontaneous dizziness and nausea No otological diagnosis was made She was then given bending exercises and promethazine chlorotheophyllinate (' Avomine ') 25 mg t.i d and reported an immediate improvement in her dizziness, maintained during follow-up

Symptoms

Of the 12 patients 8 (see table) had episodes of frank rotatory vertigo, usually of brief duration Case 5 had paroxysmal nystagmus of the benign positional type

Non-vertiginous symptoms attributable to vestibular disorder occurred in 9 patients and were described variously as giddiness, dizziness, unsteadiness, or impairment of balance In 5 patients (cases 4, 6, 8, 10, and 12) these symptoms were worse on movement, in case 2 after getting off a bus or a train, and in case 9 only during rapid movement of the head

Of the psychological symptoms the most common were panic attacks (7 patients), fears of travelling (5 patients), reactive depression (5 patients), feelings of tension (3 patients, in 2 of whom it was particularly severe in the barber's chair), and exhaustion (2 patients)

Treatment

An explanation that the primary disorder is an organic affection of the balancing mechanism often affords great relief to the patient, who may have been fearing insanity or a grave organic disorder Balancing exercises not only give confidence but also appear to hasten the disappearance of feelings of unsteadiness Three forms of balancing exercise were given, the simplest (cases 4, 5, 7, 11, and 12) being putting the head between the knees from a standing position ten times in succession, to be repeated several times a day (" bending exercises ") A full range of balancing exercises, from eye and head movements to vigorous bending (Cawthorne 1946, Cooksey 1946), was given to some of the patients, and was continued either at home (by cases 1, 3, 9, and 10) or in the physiotherapy department (by cases 2, 6, and 8) The simple bending exercises may suffice, but better results were obtained with the full range of balancing exercises Sedatives by day or night

ANALYSIS OF CASES

Case no	Sex	Age (yr)	Duration vestibular disorder (yr)	Rotatory vertigo	Non-rotatory vestibular symptoms	Reproduction of vertigo (V) or non-rotatory vestibular symptoms (I) by caloric test	Anxiety symptoms		Previous neurosis (severity 0–3)	Duration of follow-up after first being seen (yr)	Progress after treatment
							Severity (1–4)	Duration (yr)			
1	F	24	1/12	Late	+	V+1	4	1/12	1	1	Recovered
2	M	52	11	−	+	1	4	6	1	2 1/2	"
3	M	43	31	+	−	V	2	5	1	1	"
4	M	43	8/12	−	+	−	4	8/12	2	3/12	Improved
5	F	57	27	+	+	V	4	27	1	11/12	"
6	M	28	7	+	+	−	4	2	1	2	Recovered
7	F	26	9/12	+	−	−	2	6/12	0	5/12	"
8	F	16	6/12	−	+	?	4	9/12	3	6/12	I S Q
9	M	40	2	+	+	V	1	8/12	1	1 3/12	Recovered
10	F	28	6/12	−	+	1	4	3/12	0	7/12	Improved
11	F	25	1 6/12	+	−	V	3	1 6/12	0	1	I S Q
12	F	38	1 5/12	+	+	1	3	9/12	0	9/12	Improved

were given when they seemed required, but cases 7 and 9 recovered when bending exercises were introduced and sedatives stopped Antihistaminics were given to 5 patients (dimenhydrinate 50 mg t i d in cases 4, 5, 10, and 11, and promethazine chlorotheophyllinate 25 mg t i d in case 12) at the same time as exercises, and any independent effect they may have had could not be determined

Discussion

Vertigo has long been known to cause anxiety and the fear of further attacks On the other hand, complaints of unsteadiness, subjective and objective, are a classical feature of anxiety states and hysteria The present patients were all considered to have a vestibular disorder, 4 without rotatory vertigo and 3 without symptoms of unbalance between their attacks of vertigo In all the patients the outstanding and disabling symptoms were attributable to anxiety consequent on the vestibular disorder Usually those without previous neurotic traits were less severely affected as regards their anxiety symptoms, as would be expected, but their outcome was no better Absence of rotatory vertigo was an unfavourable prognostic symptom 3 patients (cases 2, 5, and 12) had had long periods of psychiatric treatment without any improvement until the organic basis of their disability was recognised The response to treatment by explanation and exercises was encouraging, 6 patients becoming free from anxiety, and 4 others showing definite improvement

From the otologist's point of view these cases present considerable difficulty The tests for vestibular disturbance are still relatively undeveloped, and while the differential caloric test of Fitzgerald and Hallpike (1942) is most helpful it cannot provide conclusive evidence in every case The difficulties of the test are well known the test needs an expert to apply it, and the margin of error of the test should lead to reserve about its interpretation in the absence of other signs In vestibular neuronitis there may be a complete lack of vestibular response on one side, whereas the other may be normal, and in this event a diagnosis can be made with certainty On the other hand, the equally well-known condition of benign paroxysmal nystagmus, when transient vertigo develops with the head in certain positions, may be associated with a normal response to the differential caloric test In benign paroxysmal nystagmus the signs may wax and wane, so that a patient may have this disease and yet, if his visit to hospital coincides with a period of freedom, may show no sign to the examiner The possibility, therefore, that a patient with this disorder may be thought to be entirely neurotic should make for hesitation in assessing a patient who is described as a victim of vertigo These patients should certainly be examined as thoroughly as possible, and it is a reasonable suggestion that no one who can complain in detail of an apparent movement of objects should be considered neurotic Whether this complaint can be confirmed by objective evidence is uncertain, it clearly can sometimes, but there is often doubt because the available vestibular tests are not sufficiently accurate That a patient with an established disorder—such as Ménière's disease—can develop a neurosis is equally well known All otologists will know of patients with Ménière's disease who were considered to be neurotic, simply because the neurosis which had developed was so obvious that it concealed the Ménière's disease There is no reason why this should not happen in other vestibular disorders, and in future more precise methods of examination may supply proof of organic disease in patients who would otherwise be considered neurotic

The caloric responses of the present patients cannot be attributed to anxiety, because they differ from those found by Hallpike et al (1951) in 35 patients with severe anxiety neurosis, who showed greater overall sensitivity with a greater degree of variance than did a healthy group

Our patients were extracted from 466 consecutive patients without organic disease of the central nervous system referred to one of us (R T C P) for psychiatric opinion by the physicians of the neurological hospital over a period of three years Thus the syndrome appears to be common, although it may be over-represented in the material of a neurological hospital

The association between vertigo and endogenous depression is also of interest Of 146 patients with endogenous depression seen over the past three years at this hospital, in 14 a complaint of vertigo was made and was considered to have a basis in an organic vestibular disorder In 10 of these patients the attacks of vertigo and of depression were independent, in 3 the onset of vertigo led directly to a recurrence of a depressive state, and in 1 the onset of vertigo led to the initial attack of endogenous depression It is therefore possible that vestibular disorders may be counted among those physical illnesses incriminated by Roth and Kay (1956) as responsible in some patients for the precipitation of an attack of endogenous depression

Summary

An account is given of 12 patients in whom anxiety states directly followed disturbances of balance and in whom the symptoms attributable to anxiety predominated

The prognosis of these anxiety states depended largely

on recognition of the primary disorder and on treatment by balancing exercises.

We wish to thank our colleagues at Maida Vale Hospital for referring these patients to us, and Dr. Eliot Slater and Dr. Alick Elithorn for their advice and criticism.

SKELETAL muscle necrosis leading to acute tubular necrosis of the kidneys is a rare complication of carbon-monoxide intoxication.

Günther (1921) recorded fatal renal damage, with oliguria, in an adult male following eleven hours' coma due to exposure to carbon monoxide in a cold atmosphere; an abnormal pigment, described as hæmatoporphyrin, was found in the urine. The necropsy findings in the same case (Scharmann 1921) revealed degeneration of the muscles in the areas affected by postural pressure.

Hedinger (1948) reviewed 30 cases of muscle necrosis in carbon-monoxide poisoning; the affected muscles were painful and swollen, and in 12 cases histological confirmation was obtained.

In Fowler's (1954) case of gangrene in a lower limb, following carbon-monoxide poisoning, peripheral vascular disease was probably an important factor. The patient, a man aged 58, had a previous history of intermittent claudication, and his femoral artery, on amputation, showed gross atheroma with medial calcification. No reference was made to renal lesions in this case.

Mautner (1955) described a case of attempted suicide with carbon monoxide, in which temporary oliguria with a non-protein-nitrogen level of 85 mg. per 100 ml. was associated with brawny œdema of the right shoulder, upper arm, and thorax, and muscle necrosis was found on biopsy. Mautner credits Larrey (1812) with the first description of muscle necrosis in carbon-monoxide poisoning. Probably, however, the sacral and scapular lesions were superficial pressure sores rather than areas of muscle necrosis. There was no reference to renal lesions in these cases.

The present paper records the clinical and pathological findings in a fatal case of acute tubular necrosis of the kidneys following myonecrosis in coal-gas poisoning, and emphasises the importance of frequent clinical and laboratory assessment of such cases in view of the particular biochemical hazards in renal failure from this cause.

Case-report

A female Indian student, aged 23, was found unconscious in a gas-filled room on Sept. 24, 1957. On admission to hospital an hour later she had recovered consciousness but complained of pain in her back and in both legs.

On examination she was an obese girl of healthy appearance, who made no spontaneous movements of either leg and had a variable degree of hypoæsthesia to pinprick. Direct questioning revealed no history of suicidal intent, the accident having occurred through ignorance of the mechanism of gas-heating. She had probably been unconscious for at least seven hours, and the position of her lower limbs on discovery suggested an initial squatting posture.

Progress.—Next day she vomited several times and passed less urine (not accurately recorded). Within the next twenty-four hours she passed only 180 ml. of urine, and on Sept. 27 her blood-urea level had risen to 163 mg. per 100 ml. Her blood-pressure was 115/80 mm. Hg, and she had no anæmia. Gynæcological examination revealed no abnormality. No past history of renal disease, diabetes, or exposure to known renal toxins was obtained. Catheterisation of the bladder on Sept. 28 produced 90 ml. of urine with Sp. gr. 1·016 and moderate proteinuria but no glycosuria. Conservative treatment of acute renal failure was instituted with hypertonic dextrose solution administered through a polyethylene catheter into the superior vena cava.

On Sept. 30 an extensive soft-tissue swelling, with œdema of the overlying skin, was observed to involve the inner side of the right thigh and to extend above the inguinal ligament. There was extreme local tenderness but no superficial bruising. Limitation of internal rotation at the right hip-joint was present, and the limb was held in a position of external rotation. There was, however, no shortening of the leg. Tendon-reflexes were absent on the right side, and neither plantar response could be elicited. Appreciation of pinprick was impaired, but a segmental distribution could not be defined.

At this stage, six days after the onset of oliguria, acidotic breathing was noted, though the patient remained fully conscious, with blood-pressure 120/85 mm. Hg, optic fundi normal, and both kidneys enlarged and tender. The blood-urea level had risen to 325 mg. per 100 ml. and the serum-potassium level to 5·9 mEq per litre. Electrocardiography showed minimal peaking of T waves in precordial leads. There was a significant acidæmia, with serum-bicarbonate level 16·9 mEq per litre. The hæmoglobin level was 13·9 g. per 100 ml., white blood cells numbered 4000 per c.mm., and the erythrocyte-sedimentation rate was 12 mm. in the first hour (Westergren). Radiography of the lumbosacral spine and hip-joints was normal.

On Oct. 1 the patient passed only 90 ml. of urine. Her blood-urea level was 335 mg. per 100 ml., serum-potassium level 6·8 mEq per litre, and serum-bicarbonate level 12·8 mEq per litre. Soluble insulin was added to the intravenous infusion, and an attempt was made to give ion-exchange resin by mouth though vomiting was still frequent. On Oct. 2, although the blood-urea level had risen to 470 mg. per 100 ml., the patient's general condition was satisfactory and vomiting less troublesome. There was no impairment of consciousness, and she could now move the affected leg, which, however, was still swollen. Her serum-bicarbonate level remained at 12·7 mEq per litre, and her serum-potassium level was 7·0 mEq per litre. Preparations for hæmodialysis with an artificial kidney were being made, when the patient collapsed suddenly at 6 A.M. on Oct. 3 with impalpable pulse and unrecordable blood-pressure and died within a few minutes.

Necropsy findings.—The body was that of a well-built obese young Indian woman. The upper third of the right thigh appeared swollen, and incisions into it revealed œdema of the subcutaneous tissues The underlying adductor-muscle group, for about twelve inches of its length, was abnormally pale, yellowish-grey, and patchily mottled Some areas presented a “ fish-flesh ” appearance The muscles of the other limbs showed no abnormality The meninges and cerebral hemispheres were congested, and the brain was œdematous The heart was normal in size, with healthy valves, coronary arteries, and aorta There were bilateral terminal congestive changes in the lungs, with a normal pulmonary arterial tree Acute congestion of the liver was present The kidneys were pale and swollen, weighing 210 and 220 g The tense capsule stripped readily from the renal substance, and the cortex was pale, moist, and increased in width The medulla was mottled dusky red, and its junction with the cortex was indistinct There was no occlusion of the renal vessels The uterus and adnexa appeared healthy

Histology —Sections from the affected muscle revealed changes varying from loss of striation to complete degeneration of fibres (fig 1) Most fibres appeared waxy, with fragmentation, vacuolation, and shrinkage of degenerate sarcoplasmic remnants In some areas phagocytosis of dead muscle by histiocytes was seen, while elsewhere empty sarcolemmal sheaths were evident Areas of hæmorrhage between the muscle bundles were prominent in one section There was interstitial œdema with invasion by polymorphs, eosinophils, and lymphocytes No calcification was seen Many arterioles showed fibrinoid necrosis with intraluminal thrombi in some instances There was much perivascular cuffing with polymorphs and mononuclear cells There was no abnormality of the larger vessels Sections of the kidneys revealed glomeruli which were normal apart from an eosinophil coagulum in some of the capsular spaces (fig 2) The distal convoluted and collecting tubules contained dense benzidine-positive casts Some of the proximal tubules were intact, but others were dilated and lined by flattened regenerating epithelium There was some œdema of the interstitial tissue, with infiltration by chronic inflammatory cells, and in the cortex there was evidence of a focal perivascular histiocytic reaction adjacent to ruptured tubules Sections of blood-vessels from other organs in the body showed no abnormality.

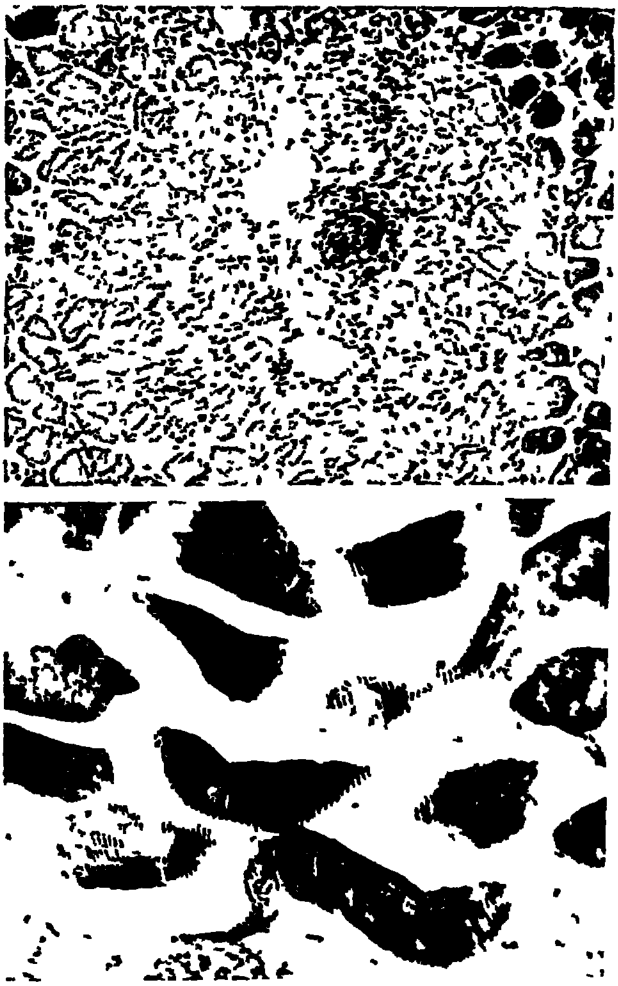

Fig 1—Section of adductor muscle showing upper part, disruption of fibres, arterial necrosis, and cellular infiltration (hæmatoxylin and eosin, ×93), lower part, loss of striation (phosphotungstic acid hæmatoxylin, ×177)

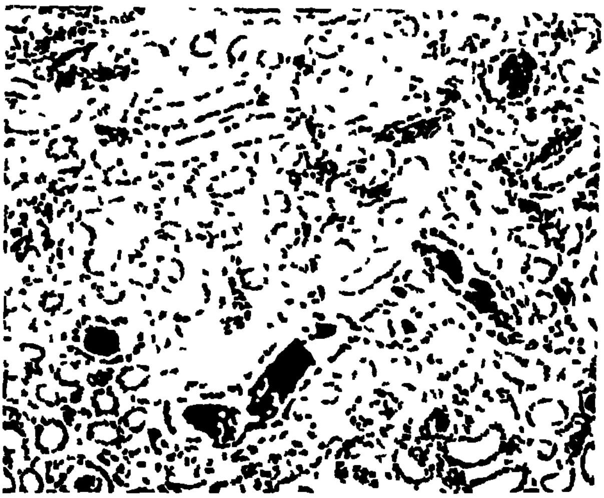

Fig 2—Section of kidney showing tubular casts and regenerating epithelium (hæmatoxylin and eosin, ×158)

Discussion

The association of myoglobinuria with acute tubular necrosis of the kidneys is well recognised Myoglobinuria results from damage to skeletal muscles, of which the main causes, in man, are trauma and Haff disease (Hed 1955) The latter condition, believed by some to be a seafood allergy, has been reported mainly in East Prussia Other non-traumatic causes, listed, by Hed, include arterial occlusion with ischæmia, convulsions, myositis, muscular dystrophy, and paroxysmal myoglobinuria without progressive muscular dystrophy The traumatic group comprises crush injuries, high-voltage shocks, and localised muscle necrosis due to postural pressure

In the present case muscle necrosis followed seven hours’ exposure to carbon monoxide, with presumed immobilisation of the patient, and was restricted to a localised area of one leg Probably the combined factors of local ischæmia due to pressure, particularly in an obese person, and anoxæmia, due to carbon monoxide, were responsible for the muscle damage The importance of decreased arterial oxygen, due to carbon monoxide, has been emphasised, perhaps in such cases the gas interferes directly with the oxidative enzymes of muscle by forming carboxymyoglobin Histologically there was no evidence of generalised arterial disease, sections of vessels from other organs being quite normal

Pressure necrosis of muscle has been reported to follow unconsciousness due to other agents, including alcoholism, alcoholism plus “ sleeping tablets ” (Jasinski and Brutsch 1952), barbiturates (Touzé and Thierry 1952), alcoholism plus barbiturates (Fahlgren et al 1957), and general anæsthesia (Gordon and Newman 1953) In some of the published cases the patients were obese, and the assumption of an abnormal posture during immobilisation has been emphasised

Most of the published cases of muscle necrosis following prolonged coma have been followed by acute renal failure In some such cases myoglobin pigment was found in the urine during life, whereas in others pigment casts in the renal tubules were found at necropsy In the present case myoglobinuria was not found, but the typical casts were present in the kidneys The histological findings were those of acute tubular necrosis, the large numbers of casts in the collecting tubules, some interstitial reaction, polymorph invasion of casts in the cortical zone, and evidence of regeneration of tubular epithelium being consistent with a duration of ten days There was no evidence of antecedent renal disease.

Early recognition of renal involvement in cases of muscle necrosis is important for the institution of a suitable regime for treating acute tubular necrosis of the kidneys Exact diagnosis depends on the spectroscopic demonstration of myoglobin in the urine, but, since this is early and probably transient, it is unlikely to be found at the stage of clinical renal failure. It is important to exclude muscle necrosis in patients developing acute renal failure after coma, particularly where it is associated with anoxæmia. A suspected clinical diagnosis can be confirmed or refuted by muscle biopsy

The renal lesion associated with muscle necrosis is potentially reversible, but the biochemical hazards, in particular that of sudden hyperkalæmia, seem less predictable than in tubular necrosis from other causes—e g ischæmic "shock" and drugs Of Fahlgren's (1957) 5 patients with myonecrosis and myoglobinuria following alcohol and barbiturate poisoning 2 died from hyperkalæmia. Hed's (1955) patient with renal failure, following the allied idiopathic condition of paroxysmal myoglobinuria, died with a serum-potassium level of 12 3 m.Eq per litre and gross electrocardiographic evidence of hyperkalæmia In the present fatal case the cause of death was presumed to be a further sudden rise in serum-potassium level above the last recorded figure of 7 0 m Eq per litre It is imperative, therefore, that such cases should have at least twice-daily estimations of serum electrolyte levels, particularly potassium, and electrocardiography Where possible they should be transferred, at an early stage, to a centre where hæmodialysis is available, if control by conservative therapy seems unlikely to prove adequate Dialysis should be considered at a relatively lower level of serum-potassium than is customary, in view of the great risk of further sudden releases of this cation into the circulation as muscle breakdown continues

In conclusion, it is emphasised that the cause of this accident was the victim's ignorance of the mechanism of gas-heating Visitors from overseas who are unfamiliar with the use of coal-gas should be instructed in its dangers

Summary

A case of fatal renal damage following skeletal muscle necrosis in carbon-monoxide intoxication is described The clinical course was that of acute, oliguric renal failure with terminal hyperkalæmia.

Postmortem examination revealed extensive muscle necrosis in one lower limb, and the changes of acute tubular necrosis with pigment casts in the kidneys

Our thanks are due to Dr G L B Thurston, H.M. Coroner, London, West District, Dr M D Milne, and Dr N F Coghill for advice and permission to publish, and to Prof T Crawford for the photomicrographs

Preliminary Communication

SELECTIVE PLACENTAL TRANSFER OF SERUM-PROTEINS IN THE RHESUS

THE transfer of antibodies from mother to young before and after birth has been studied in many laboratory animals and in man[1] Nearly all the evidence for their transmission to the fœtus has been based on immunological studies comparing the titre of specific antibodies in maternal blood with their titre in fœtal or cord blood. Although it has been assumed that in man their transfer is directly via the placenta, comparative studies in orders other than the primates have led Brambell et al[2] to suggest that the route in primates may be via the amniotic fluid, selection of γ-globulins taking place at the entodermal lining of the fœtal gut.

The transmission of other serum-proteins from mother to fœtus has received little attention Whipple et al[3] studied the transfer of ^{131}I-labelled serum-proteins in rabbits and dogs Labelled protein (unspecified) was found in the rabbit fœtuses but not in the dog The transfer of heterologous albumin has been demonstrated in the rabbit, using immunological measurement[4] So far, however, there has been no study of the transmission of homologous serum-proteins to the fœtus of any animal

Since a hæmochorial placental system comparable to that of man is found only among the catarrhine and anthropoid primates, the problem in relation to man can be investigated only in Old World monkeys or in apes The placenta of the rhesus (catarrhine) comes to resemble the human placenta very closely in the later stages of pregnancy[5]

We present here evidence of the selective transmission of whole homologous serum-proteins from mother to fœtus in the rhesus monkey, and demonstrate that the amniotic fluid plays an unimportant part in the transfer of whole serum-proteins

MATERIALS AND METHODS

Pregnant rhesus monkeys (*Macaca mulatta*) (B, C, D, and F) weighing 6–8 kg, and a green monkey (*Cercopithecus æthiops*) (E) weighing 5 2 kg, were used The monkeys were estimated to be within 4–6 weeks of the end of their gestation period (6 months) A sample of their blood was taken, and they were then given iodide water (0·02% NaI) to drink ad libitum for 1–2 days before the experiment and throughout its duration. Of this sample 0 3 ml of serum was iodinated with an average of not more than 1 atom of iodine per molecule of protein.[6]

The doses prepared contained 1 6–1 8 mC of ^{131}I in 20 mg of serum-proteins(350–400 million counts per min), of which less than 2% was free iodide

Undialysed serum-protein samples (1 0 ml) were separated by electrophoresis in borate buffer (μ=0 05, pH 8 5) on treated cellulose columns The columns (38 × 1 cm) were developed for 8$^1/_2$ hours with 600 volts The proteins were eluted with buffer in 2 ml fractions γ-globulins in unhæmolysed serum samples were isolated after dialysis against 0 02 M phosphate buffer (pH 6 2) on 1 g columns of diethylaminoethyl cellulose (D E A E)[7] and eluted with buffer in 2 ml fractions Most serum and liquor samples were also similarly fractionated after passing through ‘Deacidite’ FF (Permutit Co , an anion exchange substituted polystyrine, 100–200 mesh, in sodium form) used to adsorb residual free iodide after iodination of the dose Radioactivity was measured in a well-type scintillation counter with an efficiency of 16 2% for ^{131}I and a background of 130 c per min All samples were counted for a minimum of 4000 counts, except for very weak samples on column fractions which were counted for 1000 counts The protein in each column fraction was measured at 280 mμ in a ‘Unicam’ spectrophotometer and then counted

Red blood-cells taken from the mother at the same time were labelled with 0 8–1 0 mC carrier-free ^{51}Cr for an hour at room temperature in acid citrate dextrose (A C D) After washing thoroughly in saline (final activity=37,000 c per min per mg Hb) they were stored in A C D at +4°C until use within 24 hours Fœtal red cells were washed in saline (6 × 15 ml) and 3 ml of packed cells counted in the scintillation counter

EXPERIMENTS ON TRANSPLACENTAL TRANSFER

(Monkeys B, C, and D)

Procedure

The ^{131}I-labelled serum was mixed with the ^{51}Cr-labelled red cells and injected intravenously into the mother Anæsthesia was induced 8–9 hours later with thiopentone and maintained with cyclopropane in closed circuit or with open ether The lower segment of the uterus was incised down to the level of the fœtal membranes, and through an avascular part 20–80 ml of blood-free amniotic fluid was aspirated with needle and syringe The fœtus was delivered and exsanguinated immediately by open heart puncture A sample of maternal blood was taken just before or just after delivery of the fœtus

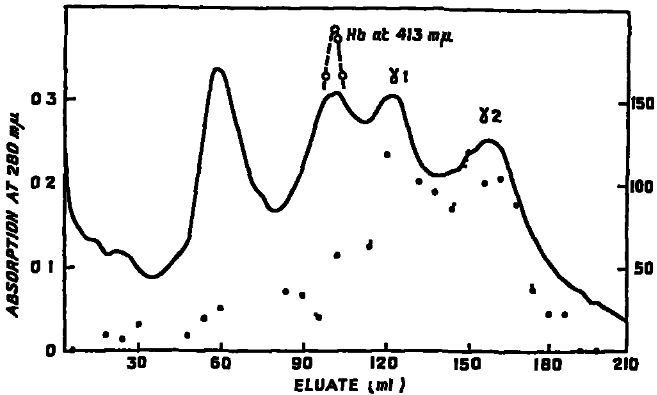

Fig 3—Eluate of column electrophoresis of 1 0 ml of fœtal serum (untreated) showing the presence of labelled γ1 and γ2 globulin 8 hours after the dose (monkey C)

Results

3 ml of packed fœtal red cells gave a count not significantly above background, indicating that there had been no gross contamination with maternal blood due to accidental hæmorrhage in utero Column electrophoresis of the ^{131}I-labelled dose in carrier serum indicated that, although the specific activity of the albumin peak was always 2–3 times the specific activity of the globulins, the count pattern followed the protein (absorption at 280 mμ) pattern closely About 80% of the total counts were with the albumin, about 4% in the γ-globulin isolated chromatographically, and, by difference, about 16% in the other globulins Fœtal serum (fig 1) contained radioactivity in the albumin peak and γ-globulin-fraction peak Some of the activity of the albumin appeared to be due to adsorbed free ^{131}I iodide, which was removed by deacidite FF (fig 2) Dialysis for 48 hours in 5% NaI failed to reduce the specific activity any further There were almost as many counts in the γ-globulin as there were in the albumin, indicating that

7 Peterson, E A , Sober, H A *J Amer chem Soc* 1956 ,78, 756

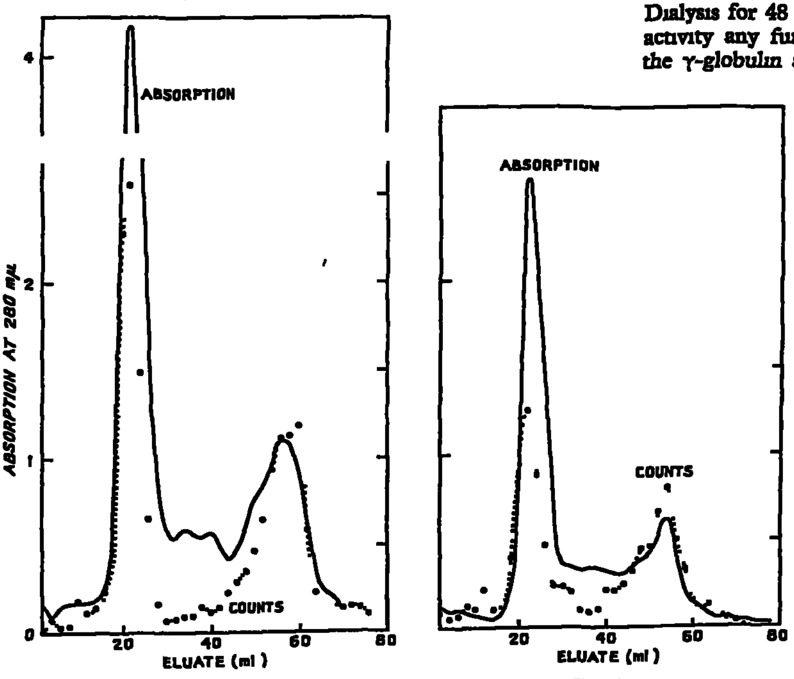

Fig 1 *Fig 2*

Figs 1 and 2—Eluate of column electrophoresis of 1 0 ml of fœtal serum untreated (fig 1) and after treatment with deacidite FF and dialysis against 5% NaI and 0 01% monoiodotyrosine (fig 2) (Monkey D, 8 hours after the dose) This shows the presence of radioactive albumin and γ-globulin (dotted line

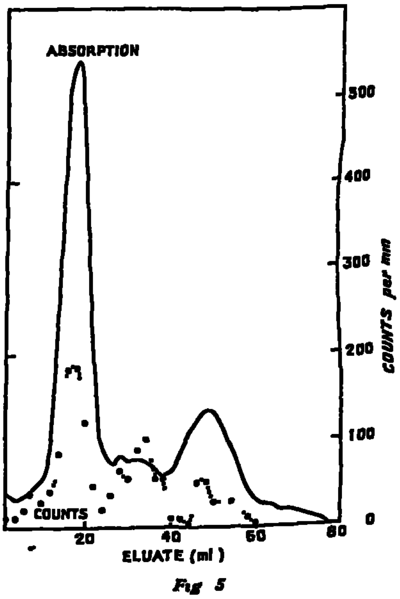

Fig 5

Fig 5—Eluate of column electrophoresis of 1 0 ml fœtal serum after treatment with deacidite FF (monkey F), 24 hours after injecting into the amniotic fluid the same amount of radioactive serum-proteins as was used for transplacental experiments B, C, and D There is little absorption of any specific labelled protein

γ-globulin was transmitted to the fœtus some 15–20 times more easily than albumin. Moreover, the γ-globulin isolated by D.E.A.E chromatography accounted for almost all the counts in the β and γ globulin fractions Fig 3 shows that prolonged column electrophoresis demonstrated the presence of both 1 and γ2 labelled globulin

Electrophoresis (fig 4) showed that the specific activity of the albumin in the amniotic fluid was about 5 times that of the albumin in the fœtus, but apparently no other labelled protein was present in significant quantity The amniotic fluid of the rhesus and green monkeys contained large amounts of a protein which moves on column and paper electrophoresis in the region of the α1 and α2 globulins, no peak of radioactivity was present in this position.

EXPERIMENTS ON ABSORPTION OF SERUM-PROTEINS FROM AMNIOTIC FLUID

(Monkeys E and F)

Procedure

Maternal serum-proteins prepared in the same way were injected percutaneously into the amniotic cavity, using a no 23 gauge needle in the conscious animal, after mixing with 3 ml of amniotic fluid removed previously through the same needle Samples of the fluid were taken at operation 8 hours later (E), and at 3 hours and 6 hours by aspiration through the abdominal wall and at operation 24 hours later (F) Cæsarean section was performed samples of amniotic fluid uncontaminated with blood, and of maternal and fœtal blood, were taken, and the samples were fractionated

Results

The same total amount of activity was injected into the amniotic fluid (volume 100–120 ml) as was injected intravenously in monkeys B, C, and D whose intravascular plasma volume was estimated to be about 250–300 ml

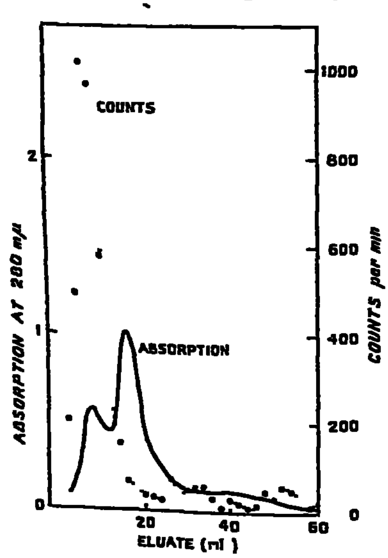

Fig 4—Eluate of column electrophoresis of the concentrate of 4·0 ml of liquor after treatment with deacidite FF (monkey D), 8 hours after the dose The protein pattern shows a small amount of albumin and a large amount of another protein in the α1 and α2 globulin position. Labelled albumin is present but no other significant peak of radioactivity in the region of the globulins

The specific activity of the albumin in the liquor of E and F obtained at 8 and 6 hours after injection was about 100 times greater than that present in the liquor at operation in monkeys B, C, and D Fig 5 shows that, after absorption of the iodide bound to albumin by passing through deacidite FF, only very small quantities of labelled proteins were present in the fœtal serum even after 24 hours Electrophoresis of serum mixed with the contents of the duodenum and jejunum, and the ileum of the fœtus of E, showed an almost normal pattern of labelled serum-proteins present in fairly high concentration. The fœtus had therefore swallowed liquor and had the opportunity to absorb proteins from the gut, and at least some of all the major components of serum-proteins had escaped digestion. The maternal serum at operation 24 hours after the dose (F) contained small quantities of labelled albumin, assuming that it had equilibrated throughout the whole albumin pool of the mother, this labelled albumin would account for very roughly 0 1% of the dose albumin Some of this might well represent some of the dose that had leaked out through the three needle tracks made through the fœtal membranes

DISCUSSION

The validity of these experiments rests on the biological normality of the ^{131}I-labelled proteins

There is now reasonable evidence that proteins iodinated with an average of 1 atom per molecule behave metabolically with close similarity to proteins labelled with ^{14}C-aminoacids, at any rate in rabbits [8 9] If labelled proteins are allowed through the placenta, then one may fairly assume that unlabelled ones can also pass Exact measurements of labelled proteins (albumin in particular) were difficult because of the tendency to adsorb free labelled iodide, which from trichloracetic acid (T C A) precipitation studies was found to be present in relatively high concentration in fœtal serum and liquor, even in the presence of carrier It is believed, however, that passing the serum through deacidite FF stripped most, if not all, of this adsorbed iodide

The experiments demonstrate two main points First, they show the direct transmission of homologous maternal albumin and γ-globulin to the fœtal circulation, this transfer is selective in that γ-globulin is transmitted some 15–20 times more easily than albumin Globulins with a mobility in the α2 and β globulin region (in the conditions of electrophoresis used) do not appear to reach the fœtal circulation This is in accord with the prediction based on studies on changes in protein-fraction concentrations in infants and children [10] Selectivity of serum-protein transfer has been demonstrated (for homologous and heterologous serum-proteins [11] and for homologous and heterologous antibodies [12] by the endoderm of suckling rats Selection of proteins in the rabbit is known to be controlled by the yolk-sac splanchnopleur, which is also entodermal [1 13 14] The transplacental selectivity in the monkey thus appears to be one of the rare instances of selection by a non-entodermal surface The selection of particular types of homologous antibody [15–20] illustrates how discriminating the human placenta can be

Secondly, it has been shown that the transfer of the albumin and γ-globulin to the fœtus is not via the amniotic fluid but is presumably transplacental In the late stages of pregnancy very little, if any, of the proteins was absorbed unchanged from the amniotic fluid This was predicted for antibodies by Wasz-Hockert et al [21] who found that in newborn infants with partial and complete œsophageal atresia the blood-level of diphtheria antitoxin was comparable with that of normal infants The likelihood that proteins are absorbed from inhaled amniotic fluid also becomes remote

The protein composition of the amniotic fluid of the rhesus monkey near term was, however, different from that of human amniotic fluid at term The total protein concentration was about one-tenth that of serum, there was a small amount of albumin, and very small quantities of β and γ globulins About 60% of the protein was of low

molecular weight, and on electrophoresis, under the conditions used, it travelled between the $\alpha1$ and $\alpha2$ globulin Whereas labelled albumin passes to the amniotic fluid from the maternal circulation, only very small quantities, if any, return to the mother Since so little gets into the fœtus we infer that there is proteolysis within the amniotic cavity

These points are under investigation, and a further report, with a quantitative analysis of the above experiments, will be given in due course

SUMMARY

The transfer of ^{131}I-labelled serum-proteins from the maternal circulation to the fœtal circulation has been investigated in near-term pregnant rhesus monkeys

The direct transfer of labelled $\gamma1$ and $\gamma2$ globulin has been demonstrated Albumin is transmitted with much less relative facility, and little, if any, other globulin is transferred Only labelled albumin was found in the amniotic fluid

Labelled maternal serum-proteins injected into the liquor were not found in the fœtal circulation 24 hours later Only extremely small quantities were found in the maternal circulation

The transfer of γ globulin is thus shown to be transplacental in one species of primate, and the placenta is shown to be another rare example of a non-entodermal membrane capable of selective transmission of protein'

It is a pleasure to thank Dr A S McFarlane and Mr R C Holloway for assistance in preparing the labelled serum, Dr K Sykes and Dr P Frost for help with anæsthesia, and Dr C P Farthing and Mr W B Brocklehurst for help at operations, and Mr D Short and Dr F Hawking for assistance in obtaining the monkeys

Reviews of Books

The Kidney

An Outline of Normal and Abnormal Structure and Function

H E DE WARDENER, M B E , M D , F R C P , senior lecturer in medicine, St Thomas's Hospital, London London J & A Churchill 1958 Pp 338 45*s*

THERE are a number of books on the kidney in which physiologists lay down canons of behaviour for the diseased kidney, or pathologists infer from their sections how the kidney must have behaved in life Neither approach has been particularly helpful in the practical management of renal disease, whose study has on the whole progressed through the recognition of clinical syndromes which can be investigated and treated even when their precise ætiology may be a matter of surmise Fuller Albright is reported to have said that we may soon know everything that matters about rheumatoid arthritis, except its cause and cure, a similar thrust could be made at our present clinical approach to renal disease, but a reading of Dr de Wardener's book goes far towards rebutting it

The background of physiology and the description of syndromes are clearly presented, with the authentic touch of the contributor to knowledge and there is also a good, if brief, account of the contribution which renal biopsy and other techniques can make to ætiological diagnosis, a proper emphasis on the importance of the treatable disease, acute pyelonephritis, some indication of the complicated relationship between renal disease or dysfunction and hypertension, œdema, and extrarenal disease, and an adequate survey of available treatment

The manner of presentation sometimes fails to equal the excellence of the matter The sequence of short and unrelated chapters towards the end of the book is irritating, and some rearrangement might help the reader here, though a sentence like the penultimate one on p 247 would defy interpretation in any context, unless perhaps A C T H is a misprint for A D H or D C A Most of the illustrations and charts are helpful, but those students with a perverse appetite for complexity will find satisfaction in figs 36 or 37

These criticisms must not obscure our view that this is a stimulating and valuable textbook, which should be read by all students of renal disease We hope that Dr de Wardener, having achieved a masterly synthesis of refractory material, may go on to excel himself in clarity in the second edition

Leptospirosis in Man and Animals

J M ALSTON, M D , F R C P E , Whittington Hospital, London , J C BROOM, O B E , M D , Wellcome Laboratories of Tropical Medicine, London Edinburgh and London E & S Livingstone 1958 Pp 367 40*s*

THERE is a lot to be said for the monograph The textbook of medicine tells us only so much bacteriology as is useful in diagnosis, that of bacteriology lays more emphasis on morphology and systematics than on epidemiology This monograph includes both and adds much more, and by its wider view allows us to make some reasonable guesses at the place in Nature of the genus Leptospira For many years the authors have been recognised as the final court of appeal in their subject Not only have they added much to knowledge but they have been liberal in their help and advice to others They seem to have read everything which has been written in all civilised tongues and they are generous in their acknowledgment of the pioneer work of the others whose portraits add interest to their book

It would be both pointless and ungrateful to search for omissions a frustrated reader can be assured that a letter to the authors will obtain a speedy and helpful reply The only suggestion which we would dare to make is that the future editions might benefit by the collaboration of a veterinary surgeon By that time it may be easier to be dogmatic on the importance of the infecting strain of leptospira We believe that in man *Leptospira icterohæmorrhagiæ* and *L canicola* produce related but not identical ailments Is there any virtue for the physician in distinguishing between infection with, say, *L australis A* and *L australis B* ? Similar problems are obvious in other branches of bacteriology (for example, with staphylococci and salmonellæ) and the answers may have considerable effect upon the future of diagnostic bacteriology

Psychiatry in the Modern World

E B STRAUSS, M A , D SC , D M , F R C P , lately physician in psychological medicine, St Bartholomew's Hospital, London London Michael Joseph 1958 Pp 70 8*s* 6*d*

IT has always been a pleasure to sit at the feet of Dr Strauss, and his many disciples will not be disappointed with this little book Drawing from his five recent articles in the *Sunday Times*, he discourses amiably about psychiatrists and psychologists, manic-depressives and schizophrenics, psychosomatics and somatotypes always clear, always sensible, and often stimulating The title may suggest a larger or more ambitious work, but the author himself admits he only touches on " the fringe of the fringe " It is a model of psychiatry made easy, however, and can be recommended to the lay public, to students, or to doctors who are looking for " an introduction to an introduction "

Especially commendable about the book is the author's neglect of sensation and his relative self-effacement it is all too easy for the writers of such books to glorify the Ego with long accounts of interesting cases completely cured and invidious comparisons of the views of others with their own Perhaps we should call a halt to these little books now, until there are some new advances for the public to be told about it will in any case be hard to improve on the writing in this one But why does Dr Strauss think that " shock therapy " is an inappropriate name for E C T ?

Effects of Radiation

SINCE the Medical Research Council's committee on radiation hazards made its report [1] in June, 1956, many new data on the biological effects of ionising radiations have been assembled, but the United Nations report,[2] made known on Sunday, shows that more than two years of intense study and analysis have not elicited answers to some disturbing questions The doubt remaining at the root of all disquiet is whether or not there is a threshold at which radiation damage begins and below which no harm results The United Nations committee (whose report is described on p 360) cannot answer this question (indeed, it is doubtful whether it will be answered in the near future) So the fears we expressed [3] two years ago, and to which we have returned from time to time, remain unrelieved

The genetic damage which additional radiation may induce and which may be manifest in later generations has been in the forefront of discussion The medical applications of radiation are here the greatest hazard—in countries where such applications are common The M R C report estimated that diagnostic radiology in Britain contributed a population gonad dose of at least 22% of natural background radiation, and the United Nations committee confirm the "at least" when they say that the values put before them for the genetically significant doses from medical procedures are "of the same order" as the doses from natural sources Background radiation supplies an estimated genetically significant dose of 3 rem in thirty years, and man-made sources (excluding environmental contamination and occupational exposure) are put in the range 0 5–5 rem For this total, diagnostic X-ray examinations are largely responsible, and 80–90% of the diagnostic dose to the gonads comes from a few types of abdominal and pelvic examination The reinforced lesson in these new estimates is that greater efforts must be made to restrict the gonad dose in medical irradiation, and stricter judgment must be used before patients are exposed to the crucial pelvic and abdominal investigations Detailed inquiries into doses administered in radiological practice are in hand in this country and elsewhere, but there is no need to wait for more facts before renewing the advice of the M R C committee that "the time has come for a review of present practice in diagnostic radiology" What has been made known in the past two or three years has already prompted caution in the medical use of radiation alarms should not be so vivid that valuable information is left unsought when it may be of vital concern to the patient, but the words of the U N report must now add a new warning "Medical and industrial procedures tending to increase radiation levels to which human populations are exposed should be carefully weighed as to such benefits or hazards as they may have"

Radiation-induced mutations are in general harmful, and increase in direct proportion to the genetically significant exposure, even at very low doses, and this accepted qualification must temper the apparent reassurance provided by the committee's figures for the genetic effect of environmental contamination by radioactive substances released in the testing of nuclear weapons If weapon tests cease this year the thirty-year "genetic" dose is put at 0 010 rem (which agrees with the M R C committee's view of "less than 1% of natural background") If tests continue according to either of the two assumptions set out on p 361, this dose may increase to 0 06 or 0 12 rem (2% or 4% of background) From these and many other figures before them the U N committee assess ("with wide margins of uncertainty", particularly about the dose required to double the mutation-rate) that a situation of fallout equilibrium, reached after long-continued testing, may be associated with from 500 to 40,000 annual instances of major genetic defect, compared with an estimated natural occurrence of 700,000 to 3 million yearly among a future world population of 5000 million The existing and expected "normal" burden of genetic defect is enormous the estimated addition by fallout is slight, but it is nevertheless an addition

When they come to put a value on the somatic risk, on what may happen to those now living as a consequence of man-made contamination of the environment, the U N committee are more perturbing People who derive most of their dietary calcium from rice and vegetables may experience a mean marrow dose of 7 5 or 17 rem over seventy years if weapon tests continue to equilibrium under one or other of the committee's assumptions In the same period natural sources give an estimated marrow dose of 7 rem Even if weapon tests stop this year, a seventy-year marrow dose of 0 96 rem is possible from fallout products This is a dose equivalent to slightly more than that delivered by 10 strontium units, and the M R C report said that "immediate consideration would be required" if the concentration of radioactive strontium in human bones showed signs of rising greatly beyond 10 strontium units For milk-drinking, rather than rice-eating, peoples the outlook is better At the highest estimate the marrow dose from fallout products will be 2 8 rem in seventy years, and if tests stop now the dose may be limited to 0 16 rem These figures, however, can be given very different meanings while nothing certain is known about thresholds Thus, on the assumption that there is no threshold for leukæmia the U N report estimates that equilibrium fallout may eventually mean 5000 to 60,000 cases of leukæmia a year But if a threshold is put at 400 rem it is unlikely that there will be any additional leukæmia If there is no threshold and tests stop soon, 400–2000 leukæmias a year may temporarily result, if 400 rem is the key level, nothing Even though these estimates are admittedly very uncertain, they must be respected for the long and careful judgment that backs them They are a warning of what *may* happen if the release of radioactive poisons is allowed to continue

As an agreed international statement of opinion based on as wide a survey as possible, the U N document is a notable achievement Its confirmation of so many of the findings of the M R C committee, pronounced more than two years ago, is a striking tribute to that committee

Fertility and Mental Illness

The extent to which people liable to mental affliction procreate has long concerned those administering mental-health policy Between the wars large families among the lower social classes led to fears (now largely dissipated) about declining national intelligence and to the closely related fear that unrestricted breeding among stock of poor mental background was creating an increasing problem of mental disorder Beliefs have sprung up with the most far-reaching effects sterilisation schemes—voluntary, pseudo-voluntary, and compulsory—have been advocated Prof Glanville Williams[1] has given us the most up-to-date and comprehensive survey of the approaches to sterilisation here and in America and argues persuasively for legalisation and wider use, although some of his grounds must remain open to question The importance of these issues and the power with which views on them are expressed make it appropriate that Prof Aubrey Lewis should have examined in detail some of the evidence His critical survey of work on the fertility of the mentally ill (but not of the mentally defective) in a Galton lecture[2] shows how few and contradictory are the facts so far obtained

He pointed out that a hundred years ago the concept of " degeneracy " was put forward by Morel,[3] and until the turn of the century it was thought that inferior stock underwent decay generation by generation, psychopathy breeding neuroses, then at a younger age schizophrenia (the origin of the term " dementia præcox "), the line being extinguished when idiocy in childhood precluded further procreation Such a tidy scheme fitted in well with current religious beliefs on reprobation and the sins of the forefathers being visited on the children, and with Lombroso's views on atavism and criminal types Henry Maudsley[4] in 1862 subscribed to it, and even Adolf Meyer agreed But in the early 1900s the pendulum swung to the other extreme, and David Heron[5] in 1907 expressed the belief that marriages of the insane were *more* fertile than others The idea of Nature's beneficent hand extinguishing its less useful members was now replaced by a fear of unrestricted proliferation among the mentally diseased Despite the exposure of fallacies in method and reasoning, the belief persisted, and it was not until the 1930s that the matter was really put to the test Dahlberg[6] in Sweden and Dayton[7] in the U S A showed independently that the pre-admission fertility of insane married women was significantly *lower* than among a comparable group of women in the general population It remained for Professor Essen-Möller[8] in Sweden to compare the two main diagnostic categories—manic-depressives and schizophrenics From a group of nearly 5000 married patients he deduced that manic-depressives were about as fertile as the general population The schizophrenics, on the other hand, were as a whole about a quarter as fertile as the general population, but more detailed analysis showed that schizophrenic men before their illness had average fertility, whereas women were about half as fertile as normals Over the years both sexes followed the national decline in birth-rate more slowly than was expected, until the pre-schizophrenic women were about as fertile as normals After the onset of the illness the birth-rates, as expected, fell greatly Patients who married after the illness (presumably mild) had developed were normally fertile Paradoxically the birth-rate was higher than expected in the year before admission On close examination this seemed to be a sociopsychological phenomenon due to postponement of admission until after the birth More recently Böök,[9] surveying a shut-off community in North Sweden, found that the fertility of marriages contracted by schizophrenics was very slightly *greater* than normal, but fertility of the unmarried schizophrenics was lower than among others, and as 75% of the men were single the over-all fertility was well below that of the normal population It appeared, therefore, that lowered fertility among schizophrenics might be an index of the lower chances of marriage rather than an effect of the disease itself The preponderance of single persons over married among schizophrenics has often been noted, Norris,[10] for example, found in English male patients about six times as many unmarried as married on first admissions The most probable reason seemed to be that the premorbid " schizoid " personality makes marriage less likely, although the protective effect of an affectionate home life and enhanced likelihood of being sent to hospital may play a part A man who is shy and indrawn is at a special disadvantage in our culture, whereas a woman of this type is more likely, perhaps, to contract matrimony It is evident, though, from Böök's figures that the probabilities vary in different environments his schizophrenic women had a much better chance of marriage than those of other communities studied

Having concluded that the fertility of schizophrenics was low, Professor LEWIS considered the possible factors maintaining the disease at its present level he subscribed to the view that spontaneous gene mutation occurs at a high rate, and he called attention to the Medical Research Council report on the possible effects of radiation [11] Mental illness, it said, is the most important single category of disease determined largely by heredity, and he believed that increased radiation may be raising the mutation-rates for these diseases

The fertility of neurotic persons is almost completely unknown One study [12] suggested a vague link between small families and feelings of inadequacy in the parents, but unpublished work at the Maudsley Hospital on a limited sample has shown no differences in fertility or in the number of single women The psychological mechanisms believed to play a part in sterility, and the sexual disturbances which so often plague the neurotic, may be expected to affect birth-rate, but so far nothing has been proved

Professor LEWIS speculated on the possible consequences of present mental-hygiene campaigns, which, very laudably, seek to instil into the public a more sympathetic and informed understanding of mental illness To play down the differences between mental and physical illness, and to ignore the genetic implications, might, he suggested, lead to higher marriage-rates among those liable to manic-depressive illness or with a schizoid personality a contributory factor might be the increasing use of treatment in the community and shorter periods in hospital With increased birth-rates among these groups there would be more children destined to become mentally ill, and such children would be in the care of parents liable to spend periods in mental hospitals—a thing which he felt no humanitarian person could regard with equanimity On this most important subject we agree with Professor LEWIS that hereditary factors should be squarely faced both by ourselves and by the public, and that the risks of marriage and procreation should be made known as fairly as possible in the light of present knowledge this is already the standard practice in the case of epilepsy, where commonly the normal marriage partner undergoes electroencephalographic examination in order that the chances of epilepsy in the children may be assessed While no-one would wish to ignore the effects of environment in the formative years of life, the psychodynamic view of causation must not be allowed to obscure the work of KALLMANN [13] and others on heredity No person must be deprived, against his will, of the fundamental right to procreate (especially at our primitive level of knowledge), but we as doctors would be doing less than our duty if we did not place the facts, as far as they are known, before our patients and the public Further work is badly needed, and no-one is better placed than Professor LEWIS to see that it is properly carried out

The Anatomy of the Cardia

FOR some time investigation of the lower œsophagus was out of phase, for diseases in this region were well documented while anatomical study lagged behind In hypotheses about the mechanism of closure at the cardia, extrinsic pinchcocks replaced intrinsic valves, while deviationists concerned themselves with the acuteness of the angle between œsophagus and stomach Recently, however, intrinsic valvular mechanisms have returned to favour By marking the anterior edge of the diaphragmatic hiatus at operation with a clip, BOTHA showed that the manner in which the crura embrace the œsophagus at the hiatus can have little effect on the closure mechanism, for when the diaphragm contracts the gastric fundus is pushed downwards in relation to the hiatus,[1] thus opening the gastro-œsophageal angle and vitiating any sling effect the crura might have at that point. Radiographically controlled studies undertaken by him with ASTLEY and CARRÉ [2] pointed to the lower œsophagus as an area which, in the majority of the 18 persons investigated, provided a pressure "barrier" between stomach and upper œsophagus, this lay above the level of the hiatus ATKINSON et al [3] confirmed this finding, they showed that the pressure differentials were removed by swallowing, and that in cases of reflux the pressure barrier was absent That the barrier in no way relies on the diaphragm for its existence they proved conclusively by demonstrating its presence in a case of hiatus hernia without reflux when the barrier was quite definitely above hiatal level In a converse fashion they found that the barrier was eliminated in a case subjected to Heller's operation when particular care had been taken not to damage the hiatus From their radiographic studies they were likewise unable to demonstrate any correlation between reflux and angle of entry of the œsophagus into the gastric hernia in cases of hiatus defect The recent findings thus suggest that a sphincter exists, if not in the palpable anatomical sense, certainly in the all-important functional sense, and in this respect JOHNSTONE's [4] report of a woman who suffered œsophageal reflux only when tired is of interest The understanding of reflux has now a firmer basis, and treatment of œsophagitis, particularly as regards surgical technique, can be designed more rationally

BOTHA [5] has now added to knowledge of the gastro-œsophageal junction by showing that many people have mucosal folds which, when drawn together, act as a cork to close the top of the stomach These folds are not valvular and mechanical but are thrown up longitudinally by contraction of muscularis mucosæ The presence of such folds has been in doubt since MAGENDIE first described them, indeed BOTHA's work left him in doubt until he began to study the living organism instead of specimens (The pathological condition of lower œsophageal ring appears to be due to hypertrophy of the muscularis mucosæ at this site [6], but the outcome is a horizontal shelf) It should occasion no surprise that several factors combine to ensure closure of the cardia, for most physiological mechanisms are complex, BOTHA hints that the relative importance of each factor varies from one person to another

---

There is need for further anatomical study to establish whether or not columnar epithelium in the lower œsophagus is a variant of normal, BARRETT [7] regards its presence there as abnormal and speaks of those with this condition as patients, even though they may be symptom-free, ALLISON and JOHNSTONE [8] presumed that the presence of gastric mucosa of cardiac type in the œsophagus may be a congenital abnormality Yet BOTHA finds that the junction of squamous and glandular epithelium is above the cardia in most people Does it really matter? The discussion which this "ectopic" epithelium has provoked seems to be out of proportion to its probable importance A full study of this histological point should give a firm statistical answer which might remove one distraction in arguments on the causation of peptic ulcer of the œsophagus And if anyone has difficulty in differentiating œsophagus from stomach (as BARRETT [7] points out, the presence of mucosa is the usual indicator) then the pressure barrier might aid in defining the lower limits of œsophagus

Annotations

B C G IN THE U S A

A LARGE trial of B C G vaccination in the U S A has been described by Palmer et al [9] This took place in two localities—Puerto Rico and two counties in Georgia and Alabama The groups studied differed considerably and were apparently subject to different risks of tuberculosis, they are therefore considered separately The Puerto Rican population consisted of children and adolescents under 19 years of age, whereas the population studied in Muscogee and Russell counties contained people of all ages, more than half being over 19 and almost a fifth 40 years old or more Among the 191,827 young Puerto Ricans there were about 40% "positive" to a 10 T U Mantoux test, among the 16,125 under 20 in Muscogee and Russell only 14% were "positive" to a 5 T U test The tuberculin-negative individuals in both trials were divided into vaccinated and unvaccinated groups The morbidity experience of the three groups—initially infected, vaccinated, and unvaccinated—was compared over periods of six to seven years The measure of morbidity was obtained from the number of cases of tuberculosis known to have arisen within these groups through the existing medical, public-health, and vital statistics reporting systems in the two localities, the people in the trials were not individually followed up and examined

Although this method may enable valid comparisons to be made within the two populations studied, it does not permit accurate comparison between them or with other similar trials In Puerto Rico the average annual incidence per 100,000 was 163 among the initially infected, 43 among the initially uninfected and unvaccinated, and 30 among the vaccinated 856 (75%) of the 1149 reported cases of tuberculosis occurred in those found to be infected at the time they entered the trial In Muscogee and Russell the corresponding rates were 78, 22, and 14, and 161 (75%) of the 216 reported cases were in those already infected It was concluded that the reduction of tuberculosis attributed to vaccination was 31% in Puerto Rico and 36% in the Georgian and Alabama districts among those not already infected when the trial began If all the uninfected in the Puerto Rican group had been vaccinated there would have been a 7 9% reduction in known tuberculous morbidity in the whole population studied in the period of six to seven years, and a 9 3% reduction in Muscogee and Russell counties

The findings are compared with those of the rather more precise trial carried out by the Medical Research Council [10] In this, the estimated reduction in morbidity that could have been obtained (assessed by individual follow-up) over a period of two and a half years in the initially uninfected was reported to be 82%, compared with the reduction of only about 30% in the American trial These and other differences between the trials are discussed in the report, and it is concluded that the apparent differences in the effectiveness of B C G vaccination are inexplicable But the two trials are not comparable in many respects—in particular, the ages of the subjects The British trial concerned only children aged 14–15, adolescents approaching the time of leaving school The efficacy of vaccination among these may not be the same as among infants, young children, or adults, even of the same race and in the same environment

Palmer et al conclude that extensive vaccination is not indicated in the United States They state that "because B C G cannot help those who are already infected, nor those who will not become infected, and may be helpful only to a portion of the decreasing few who will become infected in the future, it is apparent that vaccination cannot be very useful in controlling tuberculosis in this country" Presumably this is meant to apply to all large-scale vaccination of groups of people, whether defined by age, or by special risk of exposure to infection (such as nurses medical students, laboratory workers, and the families of known tuberculous patients) The assertion loses some of its force by containing such an indefinite attribute as "very useful" To gain even a 30% chance of preventing tuberculous illness in a baby exposed to an infectious mother might be thought very useful by the parents, and to prevent one person within each affected household from becoming ill could be considered a very useful contribution to controlling tuberculosis within the community

Whether widespread and expensive public-health endeavours to vaccinate large numbers of people is justified can be determined only by taking into account epidemiological, economic, and political factors unknown to those who are not intimately acquainted with that community A recommendation to limit or avoid using B C G vaccination as a centrally controlled public-health measure may well be right in a particular situation But such a recommendation does not condemn vaccination in all other situations—as is clearly recognised by Palmer et al —or in individual cases A measure may not be very useful for maintaining the health of the public, but it may be invaluable for preventing an individual dying The committee on therapy of the American Trudeau Society has just issued a statement on the role of B C G[11] It states that B C G has a place in preventing tuberculosis and suggests certain groups in which it might profitably be used. These are almost the same as the groups now being vaccinated in Great Britain, with the exception of the adolescent children throughout the country, the committee including only children living in areas with a high prevalence of tuberculosis The statement concludes "It is the responsibility of the physician to weigh the advantages and disadvantages in a particular situation."

SPREAD OF STREPTOCOCCI

THREE months ago[12] we drew attention to a current study by Holmes and Williams[13] of streptococcal infections and their probable sources among a large population of children in a residential Dr Barnado's Home over a period of 3½ years The reduction of so large a mass of epidemiological data to a useful form is no easy matter, Holmes and Williams have ordered their material so as to provide maximum information with maximum clarity in a way which deserves much admiration In their concluding chapters[14] they have attempted not only to assess the factors influencing individual susceptibility to streptococcal infection under institutional conditions but also to analyse the many differing effects which the organism, the host-carrier, the environment, and the method of treatment may have on the epidemic pattern in such a community

In the matter of susceptibility, the pros and cons of tonsillectomy have been much discussed Holmes and Williams' analysis shows that their tonsillectomised children individually derived moderate benefit, in that subsequently they suffered from few streptococcal sore throats The effect of tonsillectomy, however, seemed to be less in protecting the children's throats against colonisation by streptococci than in preventing clinical illness accompanying infection A potential social disadvantage which may follow tonsillectomy is the high nasal carriage-rate of streptococci during or after streptococcal throat infection, and Holmes and Williams find some indication that the non-type-specific immunity which follows exposure to group-A streptococci (whose existence was strongly corroborated by this study) may be impaired when tonsils have been removed. Moreover, type-specific immunity was found to be a significant factor in protection against reinfection under communal conditions, affording considerable protection on re-exposure to the homologous type Some evidence, too, was obtained that type-specific immunity was evoked by exposure without frank clinical infection.

Analysis of spread of infection within the subcommunities studied showed the importance of the introduction of new types of group-A streptococci Reinfection on re-exposure to a given type was rare Consecutive large epidemics were never due to the same type, and where there had been an epidemic due to one type the number of cases observed at a subsequent introduction was roughly inversely proportional to the number in the original outbreak Whether certain types of group-A streptococci are more communicable than others remains undecided It may be significant that the prevalent types showed a rather greater frequency of nasal carriage among both cases and carriers

"Dangerous carriers" are those with heavy nasal infection[15] and Holmes and Williams confirm this In the groups of children studied, the presence of nasal carriers (whether in the incubating stage or convalescent) and the arrival of new children in the community combined to cause continued spread of infection within it The fact that tonsillectomised children provided the majority of such dangerous carriers suggests that tonsillectomy has no place in controlling the spread of streptococcal infection. A much more effective measure is the eradication of streptococci from the throat by adequate penicillin treatment[16] (convalescent carriers were responsible for at least 25% of the secondary cases noted in this study) Much less important are environmental control measures bedding and air disinfection play little part in disseminating streptococci

The detailed analysis to which Holmes and Williams have submitted their data provides many valuable conclusions The underlying lesson perhaps, is that transmission of streptococcal infections is a matter of direct spread from infected individual to individual The most effective transmitter is a person incubating an infection, it probably takes a healthy or convalescent carrier longer to transmit as much

MIDGET ANÆSTHETIC MACHINES

NITROUS oxide is still the anæsthetic most commonly used for outpatients, but sometimes a more potent inhalational agent is valuable Cyclopropane has been recommended for this purpose,[17] and two highly portable apparatuses have been developed to enable a few minutes of surgical anæsthesia to be produced with this agent.

One apparatus, developed in the United States,[18 19] delivers 40% cyclopropane with 30% oxygen and 30% helium It incorporates a very small carbon-dioxide absorption canister of about 100 c.cm capacity, accordingly a closed system of anæsthesia can be obtained for 3–20 minutes This machine is also adaptable for resuscitation with 100% oxygen The other apparatus, of English origin,[20] is more simply designed to give about 1½ minutes' anæsthesia without carbon-dioxide absorption from a mixture of 50% cyclopropane, 25% oxygen, and 25% nitrogen The gases for both machines are compressed in tiny disposable cylinders Helium or nitrogen is necessary to render the mixture non-ignitable

Such simple machines have several advantages they are extremely portable, and they deliver a fixed concentration of gases that is known to produce good, though brief, surgical anæsthesia without hypoxia The safety of a single dose of a high concentration of cyclopropane can reasonably be regarded as established by the many patients who have now been satisfactorily dealt with in this way without major complications[19 21 22]

The title of Sir JOHN STOPFORD has been gazetted as BARON STOPFORD OF FALLOWFIELD, of Hindley Green in the County Palatinate of Lancaster DR STEPHEN TAYLOR becomes BARON TAYLOR, of Harlow, in the County of Essex.

EFFECTS OF ATOMIC RADIATION

United Nations Report

The United Nations Scientific Committee on the Effects of Atomic Radiation was charged by the General Assembly with the task of studying and assessing observations supplied by member states on the levels of ionising radiation and radioactivity in man's environment and their effect upon him The committee was established in December, 1955, and the report published this week records the results of a long and intensive study of a mass of information collected from all over the world The text of the report is brief far longer are the detailed annexes which summarise and analyse the technical data submitted to the committee The report represents the most complete picture of the situation yet assembled, and we publish here some extracts from it

The States represented on the committee were Argentina, Australia, Belgium, Brazil, Canada, Czechoslovakia, Egypt (later the United Arab Republic), France, India, Japan, Mexico, Sweden, U S S R , the United Kingdom, and the United States The United Kingdom was represented at the committee's first session by Prof W V Mayneord and at subsequent sessions by Dr E E Pochin

LEVELS OF RADIATION

The committee has estimated the average amounts of radiation likely to be received by populations during specified periods An averaging period of 30 years has been used as relevant to transmissible genetic changes and 70 years as far as somatic injury during the lifetime of an individual is concerned Estimates for medical examinations and occupational exposures were based upon " the present situation in certain countries with developed facilities, rather than on a forecasted world average "

Natural Sources

In certain parts of the world the natural background radiation dose may be as much as ten times greater than the worldwide average and the report points to the relevance of inquiries into the health of people living in such parts in expanding knowledge of chronic low-dose irradiation Harmful effects attributable to radiation from natural sources are not known with any certainty, but, the report adds, it seems likely that some genetic, and possibly some somatic, injury is caused in this way

Medical Procedures

In countries with extensive medical services, the radiation given for medical purposes makes the largest artificial contribution to the irradiation of the population, but no data are available for countries less fully provided with medical resources The reported values of genetically significant doses are of the same order as the doses from natural sources The contribution from diagnostic X-ray examinations greatly exceeds that from radiotherapy and radioisotope applications, and 80–90% of the total diagnostic dose to the gonads is due to relatively few types of examination of the abdomen and pelvis

The significant dose to bone and bone-marrow from medical procedures has been less closely studied than the genetically significant dose, although it may be of importance if bone tumours or leukæmia are induced by low doses of radiation Although individual marrow exposures vary very widely, the average is unlikely to differ greatly from that received by the marrow from all natural sources

Occupational Exposure

Even in countries where occupational exposure is probably greatest it is estimated to contribute to the total irradiation of the population a dose of only about 2% of that from natural sources But, the report goes on, with an increasing use of nuclear reactors and radioactive materials and probably of medical and industrial radiological procedures " this is clearly a figure which should be kept under close review "

Fallout

The committee's estimates for the genetically significant and mean marrow doses from stratospheric fallout of nuclear-test material have been computed from worldwide average deposits The radiation due to stratospheric fallout from weapons exploded so far will contribute, it is estimated, a 30-year gonad dose of 0 010 rem [1] and a 70-year per-capita mean marrow dose of 0 16 rem and 0 96 rem for two populations deriving most of their dietary calcium from milk and rice respectively The corresponding estimated doses from natural sources are shown in the accompanying table For 70-year mean marrow doses, a conversion factor of 14 turns rems into strontium units [2]

Cæsium 137 (^{137}Cs) is responsible for most of the gonad radiation from fallout It becomes distributed more or less evenly throughout the tissues, causing uniform irradiation of the whole body, and when present in the surroundings, its penetrating α-radiation causes a similarly uniform irradiation of tissues

Strontium 90 (^{90}Sr) is not a gamma-emitter and does not contribute significantly to the irradiation of any part of the body from without, but its selective concentration in bone raises problems that do not appear with ^{137}Cs The highest concentrations of ^{90}Sr in bone have been observed in children from a few months to five years old The bone-marrow exposures from fallout shown in the table are due to the ^{90}Sr content of bone and refer to the concentrations estimated for children of these ages

The ^{90}Sr concentration in bone is also affected by dietary habits and agricultural conditions and by the ratio of the amounts of ^{90}Sr to calcium in the diet, and the committee has assembled much useful data on these points The estimates for bone-marrow exposures due to fallout are given for different conditions one based on observations in the United States and the United Kingdom, where milk is the main source of dietary calcium and ^{90}Sr, and where soil calcium contents are commonly high, and the other based on data from Japan where milk products are much less used and where rice and other vegetable products form the main source of dietary calcium and ^{90}Sr and where low calcium soils are common

It is evident, the report sums up, that the exposures from fallout which are most likely to be of significance are

(*a*) Those from short-lived fission products and radioactive material from local or tropospheric fallout

(*b*) Those of the gonads and other organs from ^{137}Cs due to stratospheric fallout

(*c*) Those of bone and adjacent tissue from ^{90}Sr which also comes largely from the stratosphere

BIOLOGICAL EFFECTS OF RADIATION

Present uncertainty about the effects of low dose levels makes it imperative, the report declares, that as much relevant information as possible be collected about groups of persons chronically exposed at these levels and

---

[1] Dose in rem = dose in rad × relative biological effectiveness (R B E) R B E = 1 for X, γ, and β rays and 10 for α rays

[2] 1 strontium unit = 1 micromicrocurie of ^{90}Sr per g of calcium

ESTIMATED DOSE FROM DIFFERENT RADIOACTIVE SOURCES

Sources	Genetically significant dose (rem) (Maximum for any 30-year period)		Per capita mean marrow dose (rem) (Maximum for any 70-year period)			
Natural sources	3		7			
Man-made sources (except environmental contamination and occupational exposure)	0·5–5		Ranges beyond 7			
Occupational exposure	Less than 0·06		0·1–0·2			
			Estimates for countries deriving most of dietary calcium from milk		Estimates for countries deriving most of dietary calcium from rice	
Environmental contamination (hypothetical cases)						
Weapon tests cease at end of 1958	0·010		0·16		0·96	
	Assumption *a*	Assumption *b*	Assumption *a*	Assumption *b*	Assumption *a*	Assumption *b*
Weapon tests continue until equilibrium is reached in about a hundred years	0·060	0·12	1·3	2·8	7·5	17

Assumption *a* is that the injection-rate of radioactive material is such as to maintain a constant fallout-rate of ^{90}Sr and ^{137}Cs. Assumption *b* is that weapon tests equivalent in release and stratospheric injection of fission products to the whole sequence of weapon tests from the beginning of 1954 to the end of 1958 will be repeated at constant rate.

for whom adequate control groups exist—for instance, certain populations in areas of high natural radiation and workers in uranium mines. A W.H.O. expert committee has recently been planning such an inquiry, and they have in mind the monazite region of Kerala in India.

Genetic Effects

Exposure of gonads to even the smallest doses of ionising radiations can give rise to mutant genes which accumulate, are transmissible to the progeny, and are considered to be, in general, harmful to the human race. A dose of between 10 and 100 rads per generation would probably be required to double the natural mutation-rate in human populations. Besides increasing the incidence of easily discernible disorders, increased mutation may affect certain universal and important "biometrical" characters, such as intelligence and life-span. Continued small genetically significant exposure of a population may affect not only a correspondingly small number of individuals seriously but also most of its members to a correspondingly small extent. From the genetic facts it studied the committee concluded that exposures to ionising radiation should be reduced wherever possible, and that medical and industrial procedures tending to increase radiation levels to which human populations might be exposed should be carefully weighed as to such benefits or hazards as each may have.

Threshold or No Threshold?

The dose-effect relationship may be of two general types: the effect may be directly proportional to the dose, or there may be a threshold below which no effect occurs. Intermediate relations may be assumed to exist, represented by a curved line, showing extremely little effect at low dose, thus indicating an "apparent" threshold. All studies of the dose-effect relationship are complicated by the unavoidable presence of natural radiations. In man the annual dose from natural radiations is about 100 millirem. It is assumed that a certain amount of genetic damage in man is caused by these radiations; it is conceivable that analogous changes may occur in somatic cells and that such changes, being cumulative with age, may have adverse influences. But there is at present no evidence for such an assumption.

In human adults it is difficult to detect the effect of a single exposure to less than 25 rem, or of continuing exposure to levels below 100 times the natural. Morphologically recognisable damage may be induced by total or partial, continuous or intermittent irradiations much in excess of the currently accepted "maximum permissible levels" of occupational exposure—such damage as leucopenia, anæmia, and leukæmia. As the dose of radiation is reduced below the amounts giving rise to acute functional or morphological alterations, the reactions of the organism become more difficult to detect immediately and the effects may be progressively delayed in time. Thresholds are not easily revealed under these conditions of exposure; in fact, for some of the most delayed phenomena, the report adds, it is uncertain whether they exist. "At the present time, due to the fact that threshold doses for the delayed somatic effects of radiation are not exactly known, it must be recognised that the exposure of human populations to increasing levels of ionising radiations may cause considerable and widespread somatic damage."

ESTIMATES OF CONSEQUENCES

The report emphasises that any attempt to evaluate the effects of sources of radiation to which the world population is exposed can produce only tentative estimates with wide margins of uncertainty. Nevertheless, on the basis of the dose estimates and the available data about likely somatic and genetic effects of given exposures, the committee have tried to evaluate the possible effect of natural and fallout radiation in causing leukæmia and major genetic effects. These estimates indicate only the order of magnitude of the frequency with which effects may be produced, and "our ignorance as to whether thresholds exist . . . cause the greatest uncertainty in the estimates".

Leukæmia

The natural incidence per year in the present world population is put at 150,000, of which 15,000 is attributable to natural radiation. *If there is no threshold* and weapon tests stop this year, fallout radiation may produce an estimated 400 to 2000 cases of leukæmia annually, up to an estimated eventual total of from less than 25,000 to 150,000 cases. *If there is no threshold* and fallout is allowed to reach equilibrium after prolonged continuation of tests, the leukæmia-rate due to fallout may be 5000 to 60,000 cases per year (compared with a natural incidence of 250,000, the world population being assumed to have increased from 3000 million to 5000 million). In another series of calculations the committee assumed a threshold of 400 rem. Under these circumstances the estimates for fallout leukæmia drop to zero, unless individual bone-marrow dose exceeds the mean value by a large factor.

Major Genetic Defects

Assuming a future world population of 5000 million, the natural *annual* occurrence of major genetic defects is put *in the range 700,000* to 3 million cases Of this total, natural radiation may account for 25,000 to 1 million If tests stop in 1958, a total of 2500 to 100,000 cases may arise over subsequent years as the result of genetic damage due to fallout radiation If tests go on to equilibrium the estimate for fallout-determined genetic defects is 500 to 40,000 cases per year

CONCLUSION

In its general conclusions, the committee says that all steps designed to minimise irradiation of human populations will act to the benefit of human health Such steps include the avoidance of unnecessary exposure resulting from medical, industrial, and other procedures on the one hand and the cessation of contamination of the environment by explosions of nuclear weapons on the other "The Committee is aware that considerations involving effective control of all these sources of radiation involve national and international decisions which lie outside the scope of its work" Here footnotes to the report give the text of alternative draft proposals put before the committee by the U S S R and India The Russian view was that the data were sufficient to enable the committee to conclude that there should be an immediate cessation of test explosions This proposal was rejected, Czechoslovakia, U S S R, and the United Arab Republic voting for it and Belgium and India abstaining The Indian wording was "The physical and biological data contained in the report lead to the conclusion that it is undesirable to allow any general rise in the level of world-wide contamination because of its harmful effects and that any activity which produces such a rise should be avoided Nuclear tests are the main source at present which produce such a rise" This proposal was also rejected the voting was 5 for and 5 against, with 5 abstentions At a press conference last week, Dr Pochin said that the Russian draft implied that the committee had considered both the pros and cons of nuclear tests, whereas in fact only the cons had been within their terms of reference

MANAGEMENT OF CHRONIC PSYCHONEUROSIS IN GENERAL PRACTICE *

C A H Watts
M D Durh, D Obst
GENERAL PRACTITIONER, IBSTOCK, LEICS

The chronic diseases seen in this practice have been studied over the past fifteen months All the permanent and the frequently recurring diseases are recorded There are some 8000 patients at risk, and about a quarter of them have a chronic disease Sometimes the disease is serious (e g, cancer or tuberculosis), sometimes it is recurrent (e g, asthma or peptic ulcer), and sometimes it is comparatively trivial (e g, a lazy eye or psoriasis) Chronic mental disorders account for 14% of all the chronic patients (see table) This figure does not include the psychosomatic disorders, which account for another 30% of the chronic diseases recorded

Far and away the largest chronic psychiatric problem in general practice are the psychoneurotics, they stem from three sources chronic anxiety, inadequate personality, and unresolved depression These types of case cannot be neatly pigeon-holed under clearcut diagnoses The patients listed show, in many cases, a mixture of two or even all three sources In other words, a patient with inadequate personality who cannot face the stress and strain of life may become anxious or depressed or both, and become permanently disabled Unless the patient was known before he became ill, it is often impossible to pinpoint the cause of his illness

These patients all have symptoms which worry them but have no adequate physical basis Either their condition is permanent or they are so insecure that the least upset bowls them over, and, once ill, they take longer to recover than most people They do not appear to respond to psychotherapy If not constant attenders at the surgery, they are seen much more often than their more stable brethren Some can work, and a few reach a high standard of proficiency in their work, especially the neurotic tidy obsessional housewives Most are inferior workers, doing labouring jobs which they frequently change, absenteeism is rife, and many are permanently unemployed

CHRONIC MENTAL DISORDERS IN A GENERAL PRACTICE

Illness	No of males	No of females	Total
Psychoneurosis	60	104	164 (56%)
Epilepsy	30	26	56 (19%)
Schizophrenia	12	10	22 (7%)
Amentia	12	5	17 (6%)
Alcoholic addiction	9	4	13 (4%)
Senile dementia	4	8	12 (4%)
Paraphrenia	1	3	4 (1%)
Psychopathic personality	4		4 (1%)
Compensation neurosis	3		3 (1%)
Total	135	160	295

When I first went to Ibstock fresh from a neuropsychiatric centre, I was full of enthusiasm and tried to help some of these patients by psychotherapy

Case 1 —Mary was a single woman, aged 40 Her illness started at the age of 16, when spinal disease was diagnosed and she was put on her back for three months Since then she has always had a "weak back", although no general practitioner or specialist has been able to explain the cause. From the psychological point of view she had enough to break anyone's back She was an intelligent and very capable person, but at the age of 14 all hopes of advancement along her own lines went when she was drawn into the family business because of her mother's illness The family were thrifty and hardworking to a degree of absurdity Work and money-making were the only things that mattered Social life was frowned on, smoking and alcohol were forbidden At the age of 40 her mother still referred to her as a young girl and treated her as such

After a few sessions there was a vast outpouring of hatred against her mother, with floods of tears This psychocatharsis helped, but improvement was only temporary For months I saw her periodically for a painful session of half an hour or more She cannot improve, because she is in a hopeless trap until her parents die, and by then it may be too late She has not the training, resources, or courage to go elsewhere She cannot change either herself or her circumstances, and so she remains a chronic and troublesome neurotic

Case 2 —Susan, aged about 42, was coaxed back to work after ten years on the club with a spurious label of thyrotoxicosis She kept at work for a year or more and then relapsed, and I could not get her back to work a second time She now has a certificate for nervous debility

I tried my hand at several such problems, but with none did I achieve any lasting success My senior partner is a first-class physician, but he claims to have no interest in psychiatry Looking back over twelve years, I realise that I have not cured a single chronic psychoneurotic whom he had failed to cure I was able to help some for a limited time, but in the end I was defeated I believe that, with more time, one might be able to help more of these patients, but the hours of work required are quite out of keeping with those available in general practice

---

* From a lecture given to general practitioners at the Uffculme Clinic in Birmingham on March 19, 1958

Some timid souls, however, are helped by repeated interviews and reassurance, they come to the surgery at short intervals for maintenance doses of the most simple psychotherapy

Case 3 —Jill is an anxious woman who comes of a neurotic family When her son contracted paralytic poliomyelitis, she developed a pathophobia for herself and her family Any trivial complaint brings her to see me, and I encourage her to do this, because it is usually quite easy to listen to her story, to explain what is happening to her, and to reassure her I do not think that she has the mental capacity for deep therapy, which might make her permanently more secure She knows that I will always listen to her She is better employed getting my opinion than that of the neighbours I never deceive her, we understand each other

Case 4 —Sybil is an attractive young woman, aged 27 She keeps her house like a new pin She has been in trouble ever since I have known her First she fell out with her parents and went to live with relations Then she had trouble at work Her next difficulty was with the landlord of her rooms after her marriage After a year of misery she found a house, and then became depressed because no baby was coming along She conceived soon afterwards, and her pregnancy was the best nine months I have known her to have Indeed she has since admitted that it was the happiest time of her life This island of contentment in a sea of anxiety and depression may be significant She had an easy labour, and then troubles began with a vengeance The baby would not conform, and both the health visitor and I were fearful at times for his life and hers She saw a psychiatrist and electroconvulsion therapy was given, with only a doubtful response She now felt that she was labelled and that the neighbours jeered at her because she had been to a mental hospital "It doesn't matter where I go, I am in trouble What is wrong with me?" she asks I see a great deal of her, and although I seem to be unable to help her radically, she seems to be helped by maintenance doses of understanding, sympathy, and reassurance I am the only person she can turn to in trouble She knows I will always listen to her story, bear with her tears, and in general be a kind of safety-valve

Ideally we like to feel that the psychoneurotic patient will respond to some talking type of treatment, improve, and cease to visit us We aim at helping them over a crisis, so that they can stand unassisted on their own feet This never happens with the chronic patient, talking may help a little but never cures All the rules of formal psychotherapy are broken with this type of case A placebo is often essential, sedation is sometimes useful, and repeated examinations are on occasions unavoidable

One class of psychoneurotic looks to his bottle of medicine as an essential part of life, it is a kind of fetish The colour, constitution, or taste does not matter, so long as it is the same each time He has a kind of "apple a day" philosophy "Three doses a day keeps the illness at bay"

Case 5 —Tom was a man, aged 60, when I first knew him twelve years ago He was off work because of hypertension, but there never has been any evidence that it was really the source of his trouble He has a bottle of the same mixture every two weeks We always have a chat about gardening or grandchildren for five minutes, and then off he goes This is a happy arrangement for both of us I keep him well, he does not waste my time We both enjoy the fleeting contact

A rather more time-consuming patient is the one who likes to have a "check up" each time he calls to see the doctor He has his coat off and his chest bare almost as soon as he comes into the surgery He seems satisfied with the most cursory examination, but just feeling his pulse and looking at his tongue is not enough He is really another version of the chap who must do his quota of press-ups and physical jerks each day to prove to himself that he is still fit I think one must just accept it that the examination is just another form of placebo from which one can never wean the patient A periodic examination of these people is desirable because it is rather upsetting to find that the old neurotic has developed an inoperable growth under one's very nose They all have to die sometime, but it is as well to know when this is imminent

Sometimes a drug helps the patient by easing nervous tension, and many of these patients cannot live comfortably without a sedative, a hypnotic, or one of the amphetamine preparations This appears to do them little harm, and apart from an occasional drug rash I have seen no complications We give phenobarbitone quite freely to epileptics year after year without a qualm of conscience, and they rarely come to any harm True addicts are occasionally found These people depend entirely on the drug, which they take in increasing doses, and withdrawal causes a violent reaction This true addiction must be very rare We in Ibstock have covered about sixty years of practice between us and have never had such an addict on our hands, although phenobarbitone and allied drugs are given frequently to the chronic psychoneurotics Apart from the use of chlorpromazine in chronic or recurrent psychotics, I have found no use for modern tranquillisers I certainly do not feel that anything more useful than amylobarbitone, amphetamine, and phenobarbitone has been produced so far

There is little hope of changing the warped personalities of these people, but one can occasionally ease environmental stress Sometimes a change of work is indicated The hysterical man is often an ambitious fellow who, like many immature personalities, has an exaggerated idea of his own capability He comes to grief trying to work beyond his capacity, and by persuading him to take a less exacting job one often helps him at least for a time Occasionally a new house will make all the difference It is well known how quickly slum dwellers can make a new council house into a pigsty, but this does not always happen, and I can think of families where the new house made a big difference The help of social workers here can be most useful Rotherham, in Yorkshire, was years ahead of most places when in the early 1930s it started and completed slum clearance The rent collectors on the new estate were all social workers who had the skill and tact to advise the new occupants to keep the coal in the coalhouse and not in the bath, and so on, and the scheme worked, and very few slum dwellers did not improve in housecraft

Patients with inadequate personalities respond well to suggestions, especially from a kindly parent figure It is important to establish genuine good rapport and to become a good parent, then, even if they cannot be altered radically, the rates and taxes can be kept down by maintaining them at work as much as possible

Case 6 —When old Dan comes along complaining of pains in his testicles, I know he will have at least a couple of weeks on the club To begin with I bow to the storm, I listen sympathetically to his story, I sympathise, I establish myself in the position of the kindly parent Once firmly in that position I begin to prepare him to go back to work, this awful news must be broken to him gently It should never be "You must start work tomorrow ", but rather " You will be all right by the weekend " In this way Dan is levered back to work, and I suppose he does work for 10 months in 12, which is much better for the community than no work at all

Advice on birth control may help the mother who is already overwhelmed by the size of her family Unfortunately few of this type of patient have the wits or the self-control necessary to use it effectively I tried to induce Sylvia to use a contraceptive sponge I showed her how to use it, but she had a better method She attached tapes to it and wore it like a sanitary towel and has had a further 5 children since I gave her that advice

Depressives

Of all the patients we meet in general practice those who suffer from chronic depression are the most pitiful and, I think, the most trying They have usually seen a long list of consultants whose advice has not helped to solve their problems They may have seen a psychiatrist and had electroconvulsion therapy or refused to have it They are usually not bad enough to be certified, but many have had months in mental hospital with repeated courses of electroconvulsions and even leucotomy, and none of this treatment has helped them They are sick people, tearful, depressed, and depressing They wreck all happiness in the home with their misery and self-pity The general practitioner is left with a feeling " I have tried everything I know with this patient, and nothing helps, and I know of nothing I can do or anyone else can do to help " The chronic anxiety and hysterical state can be jollied along with understanding sedative or placebo Nothing appears to help the depressive, and there is always some risk, albeit small, of suicide So far only one of my chronic depressions has successfully taken his own life Some of these patients are reluctant to see a psychiatrist or to have electroconvulsion therapy If such treatment has not been given it is well worth a trial in these cases, even after years of depression

Case 7.—Martha was aged 36 when I first came across her Her troubles had started at the age of 16, when a young man kissed her, and she was sure she would become pregnant She came to me twenty years after this initial upset, depressed beyond words because she had missed a period She was married and claimed to want children She was not pregnant but she could not be convinced until nine months had elapsed Thereafter, though she agreed that she was not pregnant, she remained a miserable and depressed hypochondriac Talking did not help, and, although she saw a psychiatrist, she refused to have electroconvulsions This went on for five long weary years until her sister-in-law developed a depression The younger woman had electroconvulsion and improved so rapidly that my patient agreed at last to have them Much to my surprise and relief she improved a great deal She is not a robust normal person, but she is a pleasure to handle compared with what she used to be

These patients seem to have no insight into their illness, and certainly no ability to help themselves

Case 8—Ruth was diagnosed as a depressive in 1948 She saw a psychiatrist, who suggested electroconvulsion therapy, but she refused to have it, and she was never certifiable A year or two later signs of disseminated sclerosis emerged and she became even more depressed Euphoria is supposed to be characteristic of disseminated sclerosis, but it was not in her case Again a psychiatrist was consulted, but now it was decided that electroconvulsions were contraindicated by the organic lesion She is seen once or twice every week If a visit is missed, I am usually sent for Never have I known a patient with so many symptoms She is always tearful, wishes she was dead, wants to see yet another specialist, and says that surely there must be some cure for her troubles One day I spent hal an hour trying to explain the organic nature of her spasticity and how sometimes one had to accept a disability I explaine how, if a man lost his eyesight through an accident, he coul never grow new eyes, but he could adjust his life I talked t her about Douglas Bader, and I felt most convinced by all m clever arguments When I had at last finished she exclaimed " Wouldn't it be nice if you could find a cure for me ?" and then she dissolved into tears

Spouses should be allowed to unburden themselve and be encouraged by the knowledge that the doctor a least understands something of their troubles In contradistinction to the patient the spouse often shows remarkable insight This is well shown in the following case

Case 9—Elizabeth, aged 56, has been depressed ever since I went to Ibstock She went to a mental hospital as a voluntary patient and stayed only five days Her husband came to see me after Christmas last year to tell me how she had attempted suicide He had gone to do some shopping and on his return found his wife in the rain-butt up to her neck in water " If I had been going to do it I would have gone in head first," was his summing up " I think she waited on the stool until she heard me coming up the passage and then she stepped into the butt just to try and hurt me, to create a scene " I think he was quite correct in his observation

It is important to spot this depressed type of patient They are very sick people in dire need of sympathy They tend to get estranged from their families, and it is most important for the doctor to remain tolerant and understanding, even if he has little to offer by way of active treatment

Conclusions

The general practitioner should not have to carry the burden of these chronic mental patients alone He has useful allies in the district nurse, the health visitor, the duly authorised officer, and the clergy He should make full use of their help In our village the Townswomen's Guild have a rota of volunteers who befriend and visit all the chronic sick This kind of activity on the part of the community should be encouraged and extended Whether we like it or not, the psychoneurotic will remain on our hands until he dies or we die If we can find ways and means of making our association more useful to the patient, we also make it more tolerable to ourselves This section of the community is often a heavy burden on their doctors Today the fate of the chronic mental-hospital patient is under serious review The chronic mental patient in general practice is also a problem worth a good deal of attention and research

---

" Another example of a new plague threatening us now in much the same way as cholera and typhoid used to in the past is injury and death from accidents ! Accident death rates are not actually rising, except among the young men and the elderly, but they are not going down anything like quickly enough, and thus are becoming proportionately more and more important Death and injury by motor vehicles particularly is now very nearly public health problem number one The snag is that it does not lend itself easily to investigation. To begin with, the whole subject is fraught with emotion, people get terribly upset if you start asking them if they drive after having a drink or two (nearly as touchy as when you talk to them about smoking and lung cancer) That is half the trouble about the new plagues in the old days the authorities could remove the pump handle and all would be well In these days it is a matter for the individual *I* have to change *my* habits of eating and drinking or driving or smoking, and that is much more difficult to do than to get someone else to lay on a clean water supply."—Prof E MAURICE BACKETT *Listener*, May 22, 1958, p 839

Occasional Survey

THE FRONTAL LOBES AND HUMAN BEHAVIOUR *

HUGH JARVIE
M.D Glasg , B Sc. Oxon , D P M

SENIOR LECTURER, DEPARTMENT OF STUDIES IN PSYCHOLOGICAL MEDICINE, UNIVERSITY OF LIVERPOOL

It is but seventy years since the first observations were published relating changes of behaviour in man to lesions of the frontal lobes (Welt 1887–88) It is true that Harlow (1868) reported the case of a man called Phineas Gage who, after the passage of an iron bar through his head, showed a complete change of personality Both frontal lobes were severely damaged in this man, but the association between the site of the wound and the appearance of the personality changes escaped Harlow, what interested him was the fact that the patient recovered from so grave an injury

Welt's paper forms a definite point of departure, its title—" Concerning changes in character in man following lesions of the forebrain "—is clear and unequivocal Three years later Oppenheim (1890) introduced the term *Witzelsucht*, which persists today as a kind of spurious hallmark of the frontal-lobe syndrome

Many contributions have followed those early papers of Welt and Oppenheim At first based upon the effects of frontal-lobe tumours, cortical degenerations, frontal-lobe injuries, and frontal lobectomies, they have in recent years largely been derived from the study of prefrontal leucotomy and its sequelæ There is still, however, no generally accepted explanation why these frontal-lobe changes take place, and the changes themselves, and the conditions determining their appearance, remain ill defined Moreover, changes in behaviour follow lesions of other areas of the brain, notably of the temporal lobes and the hypothalamus, and it is not yet known to what extent these changes are qualitatively similar to, or different from, those that follow injury to the frontal lobes Bleuler (1951) said " The so-called frontal syndrome is not characteristic of a frontal lesion but occurs also in most other brain lesions if they are localised "

It is certainly surprising to find that, when you have worked at a particular question for years, other observers consider that it does not even exist I think that Bleuler's view is wrong, but the fact that it was possible for him to come to such a conclusion emphasises the present uncertainty

Permanent Frontal-lobe Changes

What kinds of change in behaviour follow lesions of the human frontal lobes ? To answer this question I will draw on the results of an investigation that I made into the intellectual and behavioural changes in 71 men with wounds of the brain (Jarvie 1954a, 1954b, 1956) In 46 of these men the frontal lobes were damaged

The results showed clearly that certain permanent changes in behaviour took place only when the frontal lobes were injured These changes did not take place in every case of frontal-lobe wound, but when they did they often had a particularly destructive effect on the personality They did not appear at all in cases in which damage to a frontal lobe was only slight, and in only 9 of the 37 cases in which it was severe The distribution of these changes among the 9 cases was as follows

Case no	1	2	3	4	5	6	7	8	9

—, absent, P, present, ?, doubtful

Restlessness

An increase in general activity as restlessness was noted in 5 cases and showed a remarkably consistent pattern the man would move about, to and fro, perhaps following someone, in a way not dissimilar to the quadrupedal pacing after frontal-lobe ablations in the monkey Alternating with the phases of restlessness were long quiescent periods when he stayed in bed

Increased Drive

The restlessness usually made directed activity impossible or difficult, but in 1 case the change in the man's activity took the form of a well-coordinated increased drive, such as has previously been reported after frontal lobectomy (Ackerly 1935, Rylander 1939)

Stereotyped Actions

In the monkey stereotyped actions may be superimposed upon the basic pattern of quadrupedal pacing, the animal, for example, touching a feeding-box over and over again Similar stereotyped actions are seen after wounds of the frontal lobes One man, when given a pencil, began to scribble with aimless repetitive strokes, and it was not easy to stop him, another denuded an area of his skin with repeated scratching

According to Denny-Brown (1952) these limited stereotyped actions seldom persist more than a month after the injury, yet similar actions were noted in 1 man in the present series seven years after he was wounded When interviewed he had attacks of yawning, and he went on yawning as though he could not stop He was also subject to " crazes ", when he would carry out certain actions repeatedly Once it was cleaning shoes " He keeps cleaning all the shoes in the house," said his father, " yet if he went to work in a shoe factory he would soon get tired of it."

Increased Sexual Activity

In 3 men there was an increased desire to carry out the sexual act, and they would solicit their wives persistently for this purpose, both by day and by night With one exception these men made no sexual approach to women other than their wives The exception was a man who had served several prison sentences for indecent exposure This tendency to indecent exposure, like his generally increased sexual desire, only appeared in his personality after he was wounded

Talkativeness

Increased talkativeness was a feature in 8 cases In most of these it simply took the form of a loss of reticence rather than loquacity These men would now butt into conversations, whereas before they were wounded they would have remained silent

In other cases the talkativeness was more obvious, and the man would talk for long stretches at a time There was no sense of pressure behind the talk, and these men could be interrupted, when they would listen quietly to what was being said without attempting to intervene

Inappropriate Talk

In 4 of the men who showed increased talkativeness there was nothing offensive or inappropriate in the content of the talk In the other 4, and in 1 other in whom talkativeness could not be confirmed, the talk was continually, or frequently, inappropriate in one sense or another This inappropriate talk showed many characteristics, being tactless, boastful, hurtful, crude, indiscreet, or sexual Not all these characteristics appeared in each case, but in each man certain dominant themes were apparent

Impulsive Actions

Foolhardy and impulsive behaviour was observed in 1 case.

---

* Paper read at a Symposium on the Frontal Lobes held in the University of Liverpool on March 22, 1958

Emotional Blunting

Changes in the capacity of the man to react with normal emotion to ordinary human situations and events proved exceedingly difficult to assess in these cases A few of the men whose behaviour was socially disturbing sometimes appeared to be emotionally unaware of the repercussions of that behaviour on others, but this was by no means invariable This apparent lack of emotional depth was often difficult to reconcile with their emotional warmth in other directions—for example, in their relations with their wives and families In the present series I was able to convince myself of the existence of a real degree of emotional blunting in only 2 cases

Loss of Anger Response

There was complete loss of the normal response to anger-provoking situations in 1 man, it was impossible to make him angry, even by reviling him

Other Changes

Not all the changes in behaviour that were noted after these frontal-lobe wounds persisted as permanent characteristics of the man's personality In certain cases a decrease in spontaneously initiated activity was a striking feature in the weeks and months following the injury, but this might only be perceptible as a slight decrease in initiative years later For example, one man, four weeks after he sustained a bilateral frontal-lobe wound, sat for over an hour with a thermometer in his mouth without raising any objection Within a year he had returned to his former employment, and was so employed seven years later

Emotional attacks, usually of laughter but sometimes of weeping, comparable to what Rylander has called "affective incontinence", normally disappeared within a few months of the man's being wounded, this was also the case with the excessive appetite that was sometimes reported

In none of the frontal-lobe cases was there convincing evidence of a striking, or sustained, elevation of mood, and certainly nothing similar to the spontaneous happiness and jocularity described as euphoria by Rylander (1939) in a high proportion of his cases of frontal lobectomy A few of the men that I examined within a week or two of their being wounded looked euphoric because they had ruddy complexions, appeared exceptionally well, and smiled rather freely In these cases, however, there was no subjective change of mood in the direction of elation, or such change was slight This appearance of well-being was regarded as being due to a temporary stimulation of those autonomic mechanisms that are known to be located in the basal parts of the frontal lobes and the anterior temporal region

Incontinence of urine was not confined to the men with frontal-lobe wounds, but in such cases its incidence was higher, and it was usually present for a longer time than when the wound was restricted to other areas of the brain

Explosive outbursts of bad temper were equally common in cases in which the frontal lobes were injured and in those in which they were not In many instances this explosiveness tended to persist, but it often became less prominent as time went on

Some Explanations

It is difficult to imagine that so diverse a series of changes could ever have been regarded as due to a single cause, yet two explanations of this kind have been put forward to explain the frontal-lobe changes

Scarring

One of the explanations is that the changes are due to epilepsy resulting from the scar that forms after the wound This view was favoured by Hebb (1945, 1949) Hebb and Penfield (1940) described the case of a man with an epileptic behaviour disturbance due to a scar on the frontal lobe whose behaviour was greatly improved after frontal lobectomy

In the present series at least 1 of the 9 men who showed permanent changes of character began to show changes of this type almost as soon as he recovered consciousness, and before any scar could have been formed, and epileptic attacks have not been recorded at any time in 4 of these men since they were wounded In view of this it is difficult to see how these personality changes could be due to epilepsy unless the term is extended far beyond its legitimate usage

Intellectual Deficit

Goldstein (1923, 1936, 1942) considers that damage to the frontal lobes causes a single basic intellectual deficit on which all the subsequent deviations in behaviour depend, the essential nature of this deficit is the loss in the capacity to abstract, in the intellectual sphere this is shown by the inability of the patient to grasp the essentials of a situation, either in a practical everyday setting or in certain special tests—the Goldstein-Scheerer sorting tests (Goldstein and Scheerer 1941) This deficit is not limited to conceptual tasks but affects general behaviour also The patient is able to grasp only part of a behavioural situation, hence his approach to it is faulty, and in consequence he acts inappropriately

It is not difficult to discover from whom Goldstein's views are derived It was Hitzig (1884) who, having confirmed the "silent" nature of the prefrontal areas by their lack of response to electrical stimulation, suggested that they were concerned with "abstract thinking"

The view that frontal-lobe damage causes loss of the capacity to abstract could not be confirmed in the present study All the men were examined with standard intelligence tests, tests that test processes of abstraction to a high degree Of the 9 cases with permanent changes of character intellectual deficits could be demonstrated in only 3, and in 2 of these the intellectual impairment was doubtful

I did not use the Goldstein-Scheerer tests in this investigation, but recent experience of these tests in examining brain-injured people has convinced me that deficits would be demonstrated on them only in cases in which they could also be demonstrated by more conventional tests

It is still widely held that the frontal lobes are intimately concerned with intellectual function Knight and Tredgold (1955) speak of avoiding damage to the "intellectual pathways" in the operation of orbital leucotomy to minimise personality changes Even Rylander (1939) believed, at least in part, that the personality changes were due to some kind of intellectual change He considered that changes such as tactlessness were partly due to euphoria (not a prominent feature in the cases that I have described) and partly due to a "slight blunting in the higher and more differentiated feelings upon which the social and ethical deportment is founded", but he also thought (paraphrasing Goldstein) that they depended "upon a certain intellectual incapacity to adapt oneself to the situation and to correctly appraise how one's remarks are received"

In the cases that I have described many of the men were fully aware of the change in their behaviour, they could give an account of it and were often emotionally disturbed by it It was therefore impossible in these cases to show that the personality changes depended either on emotional blunting or on a lack of intellectual awareness of the changes that had taken place

I know that mental tests are imperfect instruments, and there are aspects of human intelligence that are far beyond their capacity to assess Mental tests are, however, the best means available for measuring objectively human intellectual function If we are going to continue in the belief that the frontal lobes are some kind of special intellectual organ, we must be prepared to find a valid test that will demonstrate these presumed intellectual changes. I think that the word " intellectual " is a bad one to apply to these personality changes, and there are more accurate ways to describe them.

It is clear that there must be some anatomical basis for these changes—some essential anatomical conditions to be fulfilled before the changes appear. Some of the changes, such as the diminished spontaneity and increased appetite, might well be consistent with a general disturbance of frontohypothalamic coordination, and it has been suggested that the restlessness, which is so striking in man and the monkey, is due to damage to the caudate nucleus rather than to the frontal lobe (Davis 1951, Turner 1957).

I do not think, however, that these changes can depend to any great extent on the amount of frontal-lobe tissue destroyed, as suggested by some workers (Frankl and Mayer-Gross 1947, Meyer 1950). In the first place they may not be very obvious even after bilateral frontal lobectomy, and it is clear from recent reports that they are appearing after limited frontal-lobe operations such as cingulectomy and orbital leucotomy (Tow and Whitty 1953, Tow and Lewin 1953).

So far as I am aware, the men that I examined in the present series are still alive, and, in the absence of pathological studies, it is clearly impossible to draw any accurate anatomical conclusions from this material in spite of the excellent radiological and surgical evidence available. The only conclusion that I would draw is that these changes took place, so far as I could tell, in cases in which only one frontal lobe appeared to be damaged, and this observation is consistent with the appearance of similar changes in the few reports of unilateral leucotomy that have been published (Margolis et al. 1952).

Previous Personality

It has long been known that distinctive personality changes follow in only a small proportion of cases with frontal-lobe damage. Feuchtwanger (1923) recognised this when he studied brain-wounded men from the 1914–18 war, and in the cases that I have described personality changes of a distinctive type appeared in only 25% of the men with severely damaged frontal lobes.

Now this is a most significant fact, and I do not think that the explanation of it can be wholly anatomical. It seemed to indicate that the men who developed behaviour changes were in some way different from those who did not, and that the difference might lie in the personalities of the men before they were wounded. Part of my investigation was therefore directed to a study of the normal personalities of the men who showed significant personality changes.

The men had all been brought up in family situations that could well have affected the way in which their personalities developed. Often one parent was dominant, while the other was a cipher. In childhood they were seldom allowed to express opinions of their own, so, when they grew up, they would rarely enter into conversations or assert themselves. " I would walk away rather than get into an argument with anyone," one of them said, " I wouldn't say boo to a goose." They appeared, at least superficially, to be quiet and inhibited in temperament, hence it was not surprising that their parents looked back on them as model children.

It cannot be doubted, however, that conflicts existed beneath the quiet exteriors. These men must often have wanted to rebel against the prohibitions of their environment by making cutting remarks or to overcome a sense of inferiority by boasting—elements that now appear all too obviously in their present behaviour. The man whose talk was almost entirely sexual was preoccupied with sexual matters before he was wounded, although he was regarded by his father as " rather prudish and not interested in sex." The sexual talk was not just talk that happened, not just obscenity, it represented the now open expression of a conflict that was previously concealed.

In these men with damaged frontal lobes certain features in their personalities that were formerly kept under control come to the surface, as though the braking power in respect of these features had become less effective. This was well understood by most of them. " It's out before I can stop it," said one man referring to his tactlessness.

We are all aware of this braking power in relation to our own behaviour. Many of our behaviour patterns are formulated at a subconscious level before they are allowed active expression as speech or other motor acts. These patterns, however, are subject to a process of judgment when their appropriateness or otherwise is assessed before they are translated into action, either completely, or in a modified form. Often it is only after a pattern of behaviour has been executed that we know that it is in some way different from that originally formulated. We are aware, for example, of something that we were about to say but only realise, when we have not said it, that it would not have been appropriate. After frontal-lobe damage certain inappropriate features may be facilitated and gain motor expression before they can be modified.

Now this loss of inhibition is a very characteristic thing and probably depends exclusively on interference with the normal functioning of the prefrontal cortex. It does not extend to every part of the man's behaviour but only seems to occur in relation to those aspects over which the man had to exert a special vigilance before he was wounded, these aspects in turn depending on his personality.

Frontal-lobe Behaviour

I have tried to show that, after lesions of the human frontal lobes, certain striking changes in behaviour take place which are susceptible of explanation.

When I look at this case material again I wonder what I have missed, there remain many facets of frontal-lobe behaviour that puzzle and intrigue me. Why should disinhibition affect only certain aspects of the man's behaviour? Does this mean that we have now to consider different types of frontal-lobe organisation in different people depending on their environmental experiences? Why is so much frontal-lobe behaviour stereotyped and repetitive—not only the isolated stereotyped acts, but also the talk, the sexual behaviour, and the restlessness? Why did the man who had lost much of his capacity for emotional response look so youthful? A youthful appearance was noted by Rylander (1939) in some of his cases of frontal lobectomy. Was it that, being deprived of the emotional repercussions of living, he aged more slowly than we who are continually subject to them?

Today we seek our understanding of brain function among strange arts. We think of it in terms of the mathematical arrangements of nerve-cells (Sholl 1956), or we look for explanations in the working of calculating machines, or in the gyrations of mechanical animals. No doubt the originators of such theories have an ingenuity of mind that few of us possess, but I cannot help feeling that the answers to our questions about the functions of the human brain will not be found in that way but as they have always been found—in the careful collection of clinical facts and their pathological correlations

The investigation upon which this paper is based was carried out during the tenure of a Beit Memorial Research Fellowship, in the department of neurology, The Radcliffe Infirmary, Oxford, and I am indebted to the head of that department, Dr W R Russell, for the facilities received

Public Health

Chemical Preservatives in Food

THE nutrition panel of the food group of the Society of Chemical Industry met on April 9 to discuss chemical preservatives

Dr M **INGRAM** said that the most commonly used, and at present the most important, chemical preservatives are benzoate, sulphur dioxide, and nitrite All are weak acids, and in each case the undissociated acid is the active preservative, hence, as the pH rises, so does the amount of preservative needed to give an active level in the product All are therefore more active in acid than in neutral substances

Benzoic acid has no odour and no taste and is not volatile, but a fair amount is needed in non-acid materials It is antimicrobial and has no other known effect

The situation is rather more complex in the case of sulphur dioxide The active agent is undissociated sulphurous acid, but, besides dissociation, a series of reversible compounds is formed with sugars such as glucose and other aldehydes (but not with the dissacharide sucrose), greatly reducing the concentration of the active fraction A high limit of 2000 parts per million of sulphur dioxide is set for cordials that are to be diluted A limit of 1500–3000 p p m is set for pulps for jam making, where sulphur dioxide is lost by volatilisation in boiling, the several equilibria in such systems containing sulphur dioxide require time for their adjustment Unlike benzoic acid, sulphur dioxide has other properties—it is a bleaching agent, and inhibits the formation of brown products in food

Nitrite, usually as sodium nitrite, is widely used to cure meat, 200 p p m is the maximum but more may develop naturally from the reduction of nitrate Primarily, nitrite is used to give a good colour but it may have some preservative effect

Sodium diacetate, propionic acid, and sorbic acid have all been proposed for various purposes, but their use is not yet allowed in this country The use of esters has been suggested, but, although many are potent preservatives, they often have pungent odours and are of low solubility

About £10 million pounds' worth of fruit pulp and juice is used in this country in the food industry each year, and storage and transport and handling of this amount of material is rendered possible only by the use of preservatives The attraction of the antibiotics and of atomic radiation is that they may be able to do for the neutral foods what the chemical preservatives have done for the acid ones

Dr J M **BARNES** said that preservatives must by definition be toxic to some forms of life The degree to which they are exposed and qualitative differences in susceptibility account for the death of offending microorganisms while the consumers' tissues escape injury Toxicity tests to evaluate the safety of preservatives must include those assessing the effect of any reaction products formed between the food and the preservative

Benzoic acid has been extensively studied It is quantitatively excreted mostly after conjugation with glycine Up to 4 g has been taken daily by men without ill effect, the margin of safety is therefore very great Sulphur dioxide (or sulphite) has been studied in rats, rabbits, dogs, and man Large doses cause vomiting and abdominal discomfort There is no evidence of any specific reaction to smaller doses

Nitrites, if absorbed, can convert hæmoglobin to methæmoglobin Of the less well-known preservatives, propionates and sorbic acid are metabolised through normal pathways and are probably harmless Borates are undoubtedly toxic and probably cumulative, but the toxicity of formates or formic acid, and of formaldehyde in dilute solutions, is probably much less than has sometimes been assumed

Mr H **AMPHLETT WILLIAMS** cited work by E C Wood which suggests that until a baby is about 6 weeks old it does not produce sufficient gastric hydrochloric acid to inhibit the growth of nitrate-reducing bacteria in the stomach Nitrate *can thus be reduced to nitrite, which can be absorbed with the* formation of methæmoglobin Much water is taken in reconstituted milk, and as little as 30 p p m of nitric nitrogen in the water-supply is now regarded as potentially harmful for infants

Medicine and the Law

Death after Poliomyelitis Inoculation

ON Aug 9 a verdict of death by misadventure was returned by the Manchester City Coroner, Mr G J Pycroft, on a girl aged 2, who had been given an injection of American Salk poliomyelitis vaccine on May 27 and a second dose on July 5[1] The mother noticed no ill effects, but on July 9 the child bumped her head and three days later she died in hospital

Dr Leslie White, the pathologist, said there was no sign of injury but the brain and spinal cord showed acute signs of poliomyelitis infection He did not connect the injections of vaccine with the child's death, because of the time relationship to the fatal illness (the incubation period for poliomyelitis normally being one to two weeks) and because of the absence of any similar incident in other children injected with the same batch of vaccine It was not possible for one dose to be infected and the remainder to be free from infection

The coroner said he must accept the medical evidence, but personally he would have thought there was a strong possibility that the child's death was connected with the second injection of vaccine

Commenting on the inquest,[2] a Ministry of Health spokesman said that the Ministry was not aware that any batch of vaccine issued in this country had proved unsafe Emphasis had always been laid on the fact that vaccination did not guarantee complete protection against the disease Between the start of the vaccination programme in 1956 and the end of July, there had been 35 cases in which poliomyelitis developed within thirty days of inoculation, and with 2 exceptions these were all children During the same period over 6 million children had received two injections of poliomyelitis vaccine

In England Now

A Running Commentary by Peripatetic Correspondents

"No, George," I said firmly into the telephone "I admit that I often don't know what files are in my In-tray, still less in my Pending, but I've just been down to the Eocene layer—there was a faint outline of an ichthyosaurus between the two bottom files—and I can say with confidence that I have not got your file 'Senior Registrars, beards, long, white, as a distinctive mark of'"

When we met at lunch, George asked if I remembered old MacPrendergast. "When he retired he decided to go through all the files in his trays The bottom one, to his surprise, seemed faintly familiar, and he remembered that when he first joined us he had seen a letter dealing with St. Botolph's Hospital for the Rising of the Lights, and had called for the papers The last patient, he found, had been admitted in 1820 following George IV's coronation, and the Turnover Interval before that had been 17 years Being young and enthusiastic he had decided that, even if no other achievement could be set to his credit during his career in the Department, he would at least close this useless and redundant lazar-house After a bit, of course, he lost interest and anyway was transferred to Establishment, but now it all came back Digging down through the file, he soon passed into the longhand era and farther back to the long *ſ* for s ('*Paſſed* to you *pleaſe*')

"The black letter stumped him a bit but he managed to decipher that Thos Cromwell made it a condition of not being nationalised at the Dissolution that St. Botolph's should also admit cases of the Mother and the Wolf, Tissicks, Purples, and Livergrown, as well of course as Rising of the Lights

"He got quite excited over a 14th-century minute with a date-line 'Januarie 1390' 'Pleynte is made and y-written y-wis that in this maysondewe highte sëynte Botolphe ther be scantness of mete save onlie for the Boarde of Governaunce Chaucer was a Civil Servant, could he have written this himself? But soon he was back to a document on vellum with cheerful little illuminations of Lords of the Treasury and other queer creatures which was a draft reply for the Abbot to put up to the Archbishop suggesting that since Botolph had been a local boy who made good, and since, moreover, a Pædiatric Department had been added as a war memorial after the Senlac '*incident*'—it was politically tactless to talk about the Norman Conquest—the local outcry (*clamitatio vicinorum*) at closure would be so great that the Archbishop might wish to say that the matter was still under consideration. My Lord Abbot inserted the word 'active' (*vivida*) before 'consideration' in the draft but otherwise nothing seemed to have happened. But MacPrendergast wasn't satisfied He had at the back of his mind that there had been earlier letters—much earlier—and that in a moment of depression he had slipped them behind his bookcase There were earlier letters but unfortunately he had put them on top, not behind his bookcase, and, as they were stone tablets cut in runic characters, when he moved the bookcase Well, poor old MacP never lived to draw his pension.

"St Botolph's? Oh, still going strong Of course he never had a hope of closing it Children, and all that And yet they used to say the National Health Service would destroy local interest and patriotism about hospitals!"

* * *

Beyond a vague belief that doctors could not be the only people excused from jury service, I have never known who else shared this privilege or disability with our profession. A wrong address has just brought into my hands a summons to jury duty which includes a "List of Persons entitled to Exemption" It begins grandly enough with "Peers—Judges—Sheriffs—Provosts" (this is a Scottish list) We come near the middle, between "Keepers of Prisons—Professors in Universities" and "Certified Midwives—Officers and men . *on full pay*" (Physicians and surgeons, like advocates near the top of the list, must be *practising*, though oddly enough this does not apply to dentists) The list ends with "Income Tax Commissioners—and Lighthouse Keepers" Truly we are in distinguished company

* * *

I fear that my peripatetic colleague (Aug 2) is overhasty in his condemnation of plastic, for sessional crises were not unknown even before its use

Some twenty years ago, when seats were still substantially constructed in wood, a doctor and his wife went to a dance leaving their small child with a student as a sitter-in On their return they could not find the young woman in any of the ground-floor rooms Rushing upstairs they saw to their immense relief that the baby was sleeping peacefully, but strange noises were coming from the bathroom. The horrified doctor immediately remembered that he had varnished the seat that afternoon and had forgotten to mention it to their visitor

When the door was burst open, it was at once clear that his fears had considerable substance In his best professional manner, he reassured the sobbing and slightly hysterical girl and told her that her freedom was only a matter of moments After two unsuccessful tugs he made a third very powerful heave, lost his footing, fell heavily to the floor, and broke his leg

The situation was now serious, further professional aid was sought in the form of a plumber, who in his wisdom attempted nothing heroic but quietly unscrewed the seat An ambulance was summoned and conveyed the doctor, the girl, and the seat to the local infirmary where they were admitted to the appropriate surgical wards

According to an apocryphal postscript, the house-surgeon felt that he was too inexperienced to deal with such a complicated female case and left her for his chief's operating list in the morning Eventually the anæsthetised patient (seat still in situ) was wheeled into the theatre, and the surgeon, turning to a postgraduate student notorious for his omniscience, said "Have you ever seen anything like this?" "Yes, Sir," was the reply, "Many times, but I have never seen it framed."

* * *

I remember reading about the use of body marks (congenital and acquired) for purposes of identification after some disaster, and I seem to remember, too, that textbooks of forensic medicine dilate upon the subject. But the Police had no trouble at all in identifying a nonagenarian who dropped dead on our Transport Department steps In his pocket was a medical certificate given by me half an hour earlier, testifying that he was fit to drive a car

* * *

As headlines screamed "Paratroops fly into Amman" and "G I s land in Lebanon", I settled down to twenty-one days' terminal leave, probably the most recent "demobee" from the R.A.F In fact, the ink was still wet on my signature agreeing to serve for the specified time on the Reserve of Officers—rather a formality, as I was automatically transferred. Still, I appreciated the polite gesture

Cabinet Ministers drove into Downing Street, through a litter of photographer's flash bulbs, engines warmed up on airfields all over the world, the Navy put to sea, soldiers staggered from Q M stores under mounds of tropical kit, and I arrived home to find an ominous, official, O.H M.S letter waiting for me This was it! No sooner had I managed to get out than they wanted *me* back. By tomorrow I would be swinging on a parachute, dodging noisy bangs from bad-tempered Arabs I squared my shoulders and firmly opened the envelope. If my country needed me to defend the Commonwealth, NATO, the Baghdad Pact, UNESCO, and the Sack Line, who was I to hesitate to answer the call After all, my best blue was still almost new

"Dear F/Lt," I read, "Your Personal Clothing Card Form 667B shows that you were issued with two coats (Coats, White, Medical Officer) on Jan. 23, 1957 Please return same as soon as possible or a cheque for thirty shillings to cover Form 664B action."

Letters to the Editor

CHILDREN IN HOSPITAL

SIR,—Your editorial of July 26, What Hospitals for Children? contains such a burden of special pleading and so many mis-statements in regard to infectious hospitals that it cannot be allowed to pass without challenge First you state that these hospitals are full of children suffering from non-infectious diseases Quite shortly and simply, this is not true Then you complain that they take cases of, " pneumonia, meningitis and gastroenteritis " Why not? Must I remind you that pneumonia and meningococcal infections are notifiable diseases for the reception and treatment of which infectious hospitals were expressly set up and which they are obliged to admit if requested Gastroenteritis too is notifiable in many areas and, in my experience, is sometimes almost as infectious as measles Where else should it go?

Your proposals are certainly drastic and simple You would prohibit the admission of children to adult wards, close childrens' wards in general hospitals, small pædiatric units, and fever hospitals, and decant their contents into a small number of big pædiatric units duly equipped with cubicles which are to be set up at some unspecified date I will not dwell on the arrogant and naive assumption that pædiatricians could take infectious diseases in their stride, but even if they could there are a few practical considerations to be taken into account Normally in my unit, and those I visit, at least half the patients are adults, and if the dividing line be placed at 10 years, the proportion would be considerably higher What is to happen to these patients when the fever hospitals are closed? No doubt the pædiatricians of their charity would be prepared to treat them, but that one feels would be to subject their principles to an unbearable strain

This gibe may sound trivial or unworthy but it serves to underline why so many of us regard pædiatrics as the most artificial of the specialties A small nucleus of genuine *expertise* in the management of the first years of life has been inflated beyond all reason or recognition Thus Dr Lawson (Aug 2) tells us he has 550 beds " fully staffed and equipped to deal with *all* types of cases at all ages from 0 to 16 " (my italics), and makes no bones of his conviction that no other hospital should be allowed to admit cases in that age-group while he has an empty bed Could prerogative go further?

But in any case your proposals represent a retrograde step One of the least disputable advantages of the National Health Service is that it has brought the consultant to the patient even in the remotest village No matter how small the hospital, there is now no difficulty in obtaining the opinion of a neurologist, a dermatologist, a surgeon—or a pædiatrician—as required, and there can be no doubt that this has resulted in vastly improved standards of care Your " small number of big pædiatric units " must be not only few but far between Do you seriously suggest that the parents of a child with whooping-cough or dysentery should have to make a journey of 10 or 20 miles to see him—daily of course? If so, then I am constrained to ask, for whom do you think the hospitals exist—for the public or for the doctors who staff them?

By all means let us have big units for special treatment and facilities for X-ray, better bacteriology and virology with an ever closer liaison between all hospitals, general and special The historical separation of the general from the fever hospital has not been a good thing for either, but there was one particularly cogent reason why the fever hospital was relegated to the nearest mountain top surrounded with a stout high wall—to wit, smallpox And unfortunately that threat still exists, indeed, if air travel continues to become cheaper and speedier so that tours to the smallpox areas become commonplace, importations of smallpox are bound to increase. Then we may have repetitions of what happened in a large London general-cum-fever hospital some time ago There, some 700 beds were put out of action and more than 1000 persons set at risk by a case of smallpox disguised as chickenpox and, had not the disguise been penetrated so promptly and the situation handled so competently, grim consequences might have followed as they did at Brighton in 1951 The question is not so simple as it might appear

The truth is, Sir, that, thanks to convergence of scientific and social factors, the centres of gravity in medicine are changing rapidly as we in fevers know to our cost, our beds in the London area having been cut by 90% since 1939 Pædiatrics, it seems to me, must also cut its coat according to its cloth and grin and bear its cross as best it may Like us in the infectious world, pædiatricians have wrought so well as to imperil their own survival and though this may represent a personal tragedy to many of us, we can scarcely deplore it since undoubtedly from the national point of view it is a matter for rejoicing

South Middlesex Hospital,
Isleworth, Middlesex

G E BREEN

SIR,—I should like to record my admiration of Professor Illingworth's many years of work on the problems and needs of children of all ages under hospital conditions, problems which he has felt profoundly and now sums up in his lecture to the Central Council for Health Education published in your issue of July 26 His level-headedness in this subject, which has so many emotional undercurrents, is a great asset, as the reforms which his criticisms indicate are the more acceptable, particularly to those with power of administration But I would like to go on to support the plea made by Dr Jacoby (Aug 2) that " daily visiting is not a target to be aimed at but something to be discarded as insufficient for this purpose " particularly, I would add, for the under-fives Sir James Spence told the pædiatric world for many years that mothers were good nurses (not only for babies) The Pickerills at Auckland showed that nursing by the mother reduced cross-infection But although there is widespread acceptance of the truth of these ideas, a general disbelief in their practicability prevails In the pædiatric units of the hospitals of North Bucks (which include an isolation unit) we have nevertheless in the last few years admitted mothers with rather more than half of the children under five Visiting has in the same period gradually become completely unrestricted Professor Illingworth is right to emphasise that we should be cautious about taking a mother away from other children at home, but from the evidence our mothers have supplied and that of other non-psychiatric outside observers, we feel satisfied that the mental health of children left at home has not been jeopardised

When we admit the mother with the child we are in a sense taking on two patients instead of one She also has her needs, as has anyone in strange surroundings and with a worry on their mind These needs must be met by the pædiatric staff who (to borrow a word quoted in your leader from the Royal College of Physicians report) are " attuned " to the special needs of the mothers of sick children This state of attunement of the staff at all levels, above all of the ward sister, comes only by experience built on an initial attitude of accepting the necessity for the mother to be there The magnitude of this need,

or, as some think, its relative unimportance, is one of the main points of controversy at present The need is seen by many to be fundamental for the under-fives, certain over-fives, and any child with cerebral palsy or mental defect who may have to be admitted to hospital Keeping the mother with the child, when properly managed, certainly provides the best solution for the small child's special difficulties and stresses

This is something that can make a big contribution to the welfare of small children in hospital, but Professor Illingworth mentions the subject extremely briefly (about 1/36th of the whole article), and avoids embarking on the controversy That perhaps was wise, in that his paper as it stands is an authoritative contribution on the total welfare of the unaccompanied child in hospital He does, however, state that "the arrangement presents great psychological advantages to mother and child" Endless examples might follow this statement There is one I should like to give as it concerns attitudes and prejudices It is that when the operation or treatment is over and the time comes for the child and mother to leave the ward, we feel we know them both better as people, better than we know an unaccompanied child and visiting parent They also understand us and our purpose better A psychological advantage has certainly been gained

Stoke Mandeville Hospital,
Aylesbury
DERMOD MACCARTHY

SIR,—Certain of the statements made in Dr Lawson's letter of Aug 2 cannot be allowed to go uncorrected It is quite wrong to say that the South West Metropolitan Regional Hospital Board proposes to close Queen Mary's Hospital within the next few months, the position is that the Ministry has requested the board to examine the practicability of transferring the Fountain Hospital to Queen Mary's

It is true that the Board has no formally appointed pædiatric adviser or committee, but in this, as in other specialties, the practice is to invoke ad-hoc advice when necessary, as was done in March, 1957, when Prof Alan Moncrieff was asked to take part in discussions which then resulted in the decision to continue Queen Mary's as a 550-bedded children's hospital This manifests the inaccuracy of Dr Lawson's statement that the Chairman of the Board refused to consider the use of expert advice, and also that the Board has never shown any serious interest in the provision of beds for pædiatrics

The Board must now proceed to examine the proposal as requested by the Ministry, but the situation will not be helped by the publication of inaccurate and intemperate statements

South West Metropolitan Regional Hospital Board,

E G BRAITHWAITE

ORAL TREATMENT OF PERNICIOUS ANÆMIA

SIR,—We were interested to read Professor Castle's comments (Aug 2) on our article [1] His main criticism appears to be that similar results might have been obtained had crystalline vitamin B_{12} been given orally in the same dosage, instead of the vitamin-B_{12}-peptide complex If this criticism were really valid, then surely the problem of treating pernicious anæmia by oral therapy would have disappeared ten years ago with the discovery of the crystalline vitamin in 1948, for our *average* daily dose over the first eighteen months' treatment has never exceeded 14 μg It has, we think, been clearly established both that absorption of the crystalline vitamin when given by mouth is only about 1% in the pernicious-anæmia patient,[2] and also that the daily body requirement of vitamin B_{12} is between 1 and 2 μg This being so it seems to be an inescapable conclusion that a daily oral dose of the order we have given would have been completely inadequate to maintain a patient in health, unless the absorption of the vitamin-B_{12}-peptide complex had been considerably greater than 1%

In passing, it is perhaps of interest to mention that in an American drug magazine where our findings are criticised on one page in terms similar to those used by Professor Castle,[3] on a different page in the same issue it was stated by another author[4] that although "small doses (1–2 μg) of vitamin B_{12} are effective in causing remission" (when given parenterally) "500–1000 times as much vitamin is required when given orally" Professor Castle wishes both to retain his belief in the intrinsic factor, and also to claim—by inference—that an average daily dose of 14 μg might in any case be sufficient to maintain remission, even if intrinsic factor were absent If this is true, then intrinsic factor—assuming it exists—must be rather an inert substance We cannot help feeling that Professor Castle, by making these two claims, is wanting both the halfpenny and the gingerbread

Furthermore, we cannot share his complete confidence in short-term responses as judged by serial reticulocyte counts, no matter how carefully these are carried out In our view, there are so many variable factors influencing a reticulocyte response that it should not, in itself, be regarded as the ultimate index of the efficacy of any preparation. The only completely reliable test of any new product for the treatment of pernicious anæmia is that of time

We humbly recognise the great debt which all hæmatologists owe to Professor Castle for his work on pernicious anæmia We are, in fact, largely restating his original view[5]—which he now appears to discard himself—that pernicious anæmia is due to a failure of proteolysis However, our reason compels us increasingly to reject the belief in intrinsic factor, as currently understood New cases of pernicious anæmia are not common, and the work we have already published[1] was based merely on the first 6 cases investigated We have now accumulated considerably more evidence which we shall publish in due course, and which, up to the present, in no way conflicts either with our published results, or our interpretation of them

ATHEROSCLEROSIS AND ITS CEREBRAL COMPLICATIONS IN THE SOUTH AFRICAN BANTU

SIR,—We should like to refer to the letters from Professor Becker[6] and Mr Walker and Dr Simson[7]

Talking of apoplexy, Boyd[8] says "two factors are always associated, namely, high blood pressure and arterial degeneration the arterial lesion is nearly always an atheromatous patch It is doubtful if hæmorrhage can occur from a healthy vessel no matter how high the blood pressure" Russell Brain[9] and Fishberg[10] hold substantially the same views For this reason we were content to quote only one case of apoplexy listed by Becker[11] under "atherosclerosis" At that time we

ORAL TREATMENT OF PERNICIOUS ANÆMIA

SIR,—We were interested to read Professor Castle's comments (Aug 2) on our article [1] His main criticism appears to be that similar results might have been obtained had crystalline vitamin B_{12} been given orally in the same dosage, instead of the vitamin-B_{12}-peptide complex If this criticism were really valid, then surely the problem of treating pernicious anæmia by oral therapy would have disappeared ten years ago with the discovery of the crystalline vitamin in 1948, for our *average* daily dose over the first eighteen months' treatment has never exceeded 14 µg It has, we think, been clearly established both that absorption of the crystalline vitamin when given by mouth is only about 1% in the pernicious-anæmia patient,[2] and also that the daily body requirement of vitamin B_{12} is between 1 and 2 µg This being so it seems to be an inescapable conclusion that a daily oral dose of the order we have given would have been completely inadequate to maintain a patient in health, unless the absorption of the vitamin-B_{12}-peptide complex had been considerably greater than 1%

In passing, it is perhaps of interest to mention that in an American drug magazine where our findings are criticised on one page in terms similar to those used by Professor Castle,[3] on a different page in the same issue it was stated by another author [4] that although "small doses (1–2 µg) of vitamin B_{12} are effective in causing remission" (when given parenterally) "500–1000 times as much vitamin is required when given orally" Professor Castle wishes both to retain his belief in the intrinsic factor, and also to claim—by inference—that an average daily dose of 14 µg might in any case be sufficient to maintain remission, even if intrinsic factor were absent If this is true, then intrinsic factor—assuming it exists—must be rather an inert substance We cannot help feeling that Professor Castle, by making these two claims, is wanting both the halfpenny and the gingerbread

Furthermore, we cannot share his complete confidence in short-term responses as judged by serial reticulocyte counts, no matter how carefully these are carried out In our view, there are so many variable factors influencing a reticulocyte response that it should not, in itself, be regarded as the ultimate index of the efficacy of any preparation. The only completely reliable test of any new product for the treatment of pernicious anæmia is that of time

We humbly recognise the great debt which all hæmatologists owe to Professor Castle for his work on pernicious anæmia We are, in fact, largely restating his original view [5]—which he now appears to discard himself—that pernicious anæmia is due to a failure of proteolysis However, our reason compels us increasingly to reject the belief in intrinsic factor, as currently understood New cases of pernicious anæmia are not common, and the work we have already published [1] was based merely on the first 6 cases investigated We have now accumulated considerably more evidence which we shall publish in due course, and which, up to the present, in no way conflicts either with our published results, or our interpretation of them

Letters to the Editor

CHILDREN IN HOSPITAL

SIR,—Your editorial of July 26, What Hospitals for Children? contains such a burden of special pleading and so many mis-statements in regard to infectious hospitals that it cannot be allowed to pass without challenge First you state that these hospitals are full of children suffering from non-infectious diseases Quite shortly and simply, this is not true Then you complain that they take cases of, "pneumonia, meningitis and gastroenteritis" Why not? Must I remind you that pneumonia and meningococcal infections are notifiable diseases for the reception and treatment of which infectious hospitals were expressly set up and which they are obliged to admit if requested Gastroenteritis too is notifiable in many areas and, in my experience, is sometimes almost as infectious as measles Where else should it go?

Your proposals are certainly drastic and simple You would prohibit the admission of children to adult wards, close childrens' wards in general hospitals, small pædiatric units, and fever hospitals, and decant their contents into a small number of big pædiatric units duly equipped with cubicles which are to be set up at some unspecified date I will not dwell on the arrogant and naive assumption that pædiatricians could take infectious diseases in their stride, but even if they could there are a few practical considerations to be taken into account Normally in my unit, and those I visit, at least half the patients are adults, and if the dividing line be placed at 10 years, the proportion would be considerably higher What is to happen to these patients when the fever hospitals are closed? No doubt the pædiatricians of their charity would be prepared to treat them, but that one feels would be to subject their principles to an unbearable strain

This gibe may sound trivial or unworthy but it serves to underline why so many of us regard pædiatrics as the most artificial of the specialties A small nucleus of genuine *expertise* in the management of the first years of life has been inflated beyond all reason or recognition Thus Dr Lawson (Aug 2) tells us he has 550 beds "fully staffed and equipped to deal with *all* types of cases at all ages from 0 to 16" (my italics), and makes no bones of his conviction that no other hospital should be allowed to admit cases in that age-group while he has an empty bed Could prerogative go further?

But in any case your proposals represent a retrograde step One of the least disputable advantages of the National Health Service is that it has brought the consultant to the patient even in the remotest village No matter how small the hospital, there is now no difficulty in obtaining the opinion of a neurologist, a dermatologist, a surgeon—or a pædiatrician—as required, and there can be no doubt that this has resulted in vastly improved standards of care Your "small number of big pædiatric units" must be not only few but far between Do you seriously suggest that the parents of a child with whooping-cough or dysentery should have to make a journey of 10 or 20 miles to see him—daily of course? If so, then I am constrained to ask, for whom do you think the hospitals exist—for the public or for the doctors who staff them?

By all means let us have big units for special treatment and facilities for X-ray, better bacteriology and virology with an ever closer liaison between all hospitals, general and special The historical separation of the general from the fever hospital has not been a good thing for either, but there was one particularly cogent reason why the fever hospital was relegated to the nearest mountain top surrounded with a stout high wall—to wit, smallpox And unfortunately that threat still exists, indeed, if air travel continues to become cheaper and speedier so that tours to the smallpox areas become commonplace, importations of smallpox are bound to increase Then we may have repetitions of what happened in a large London general cum-fever hospital some time ago There, some 700 beds were put out of action and more than 1000 persons set at risk by a case of smallpox disguised as chickenpox and, had not the disguise been penetrated so promptly and the situation handled so competently, grim consequences might have followed as they did at Brighton in 1951 The question is not so simple as it might appear

The truth is, Sir, that, thanks to convergence of scientific and social factors, the centres of gravity in medicine are changing rapidly as we in fevers know to our cost, our beds in the London area having been cut by 90% since 1939 Pædiatrics, it seems to me, must also cut its coat according to its cloth and grin and bear its cross as best it may Like us in the infectious world, pædiatricians have wrought so well as to imperil their own survival and though this may represent a personal tragedy to many of us, we can scarcely deplore it since undoubtedly from the national point of view it is a matter for rejoicing

South Middlesex Hospital,
Isleworth, Middlesex G E BREEN

SIR,—I should like to record my admiration of Professor Illingworth's many years of work on the problems and needs of children of all ages under hospital conditions, problems which he has felt profoundly and now sums up in his lecture to the Central Council for Health Education published in your issue of July 26 His level-headedness in this subject, which has so many emotional undercurrents, is a great asset, as the reforms which his criticisms indicate are the more acceptable, particularly to those with power of administration But I would like to go on to support the plea made by Dr Jacoby (Aug 2) that "daily visiting is not a target to be aimed at but something to be discarded as insufficient for this purpose" particularly, I would add, for the under-fives Sir James Spence told the pædiatric world for many years that mothers were good nurses (not only for babies) The Pickerills at Auckland showed that nursing by the mother reduced cross-infection But although there is widespread acceptance of the truth of these ideas, a general disbelief in their practicability prevails In the pædiatric units of the hospitals of North Bucks (which include an isolation unit) we have nevertheless in the last few years admitted mothers with rather more than half of the children under five Visiting has in the same period gradually become completely unrestricted Professor Illingworth is right to emphasise that we should be cautious about taking a mother away from other children at home, but from the evidence our mothers have supplied and that of other non-psychiatric outside observers, we feel satisfied that the mental health of children left at home has not been jeopardised

When we admit the mother with the child we are in a sense taking on two patients instead of one *She also* has her needs, as has anyone in strange surroundings and with a worry on their mind These needs must be met by the pædiatric staff who (to borrow a word quoted in your leader from the Royal College of Physicians report) are "attuned" to the special needs of the *mothers* of sick children This state of attunement of the staff at all levels, above all of the ward sister, comes only by experience built on an initial attitude of accepting the necessity for the mother to be there The magnitude of this need,

or, as some think, its relative unimportance, is one of the main points of controversy at present The need is seen by many to be fundamental for the under-fives, certain over-fives, and any child with cerebral palsy or mental defect who may have to be admitted to hospital Keeping the mother with the child, when properly managed, certainly provides the best solution for the small child's special difficulties and stresses

This is something that can make a big contribution to the welfare of small children in hospital, but Professor Illingworth mentions the subject extremely briefly (about 1/36th of the whole article), and avoids embarking on the controversy That perhaps was wise, in that his paper as it stands is an authoritative contribution on the total welfare of the unaccompanied child in hospital He does, however, state that "the arrangement presents great psychological advantages to mother and child" Endless examples might follow this statement There is one I should like to give as it concerns attitudes and prejudices It is that when the operation or treatment is over and the time comes for the child and mother to leave the ward, we feel we know them both better as people, better than we know an unaccompanied child and visiting parent. They also understand us and our purpose better A psychological advantage has certainly been gained

Stoke Mandeville Hospital,
Aylesbury

DERMOD MACCARTHY

SIR,—Certain of the statements made in Dr Lawson's letter of Aug 2 cannot be allowed to go uncorrected It is quite wrong to say that the South West Metropolitan Regional Hospital Board proposes to close Queen Mary's Hospital within the next few months, the position is that the Ministry has requested the board to examine the practicability of transferring the Fountain Hospital to Queen Mary's

It is true that the Board has no formally appointed pædiatric adviser or committee; but in this, as in other specialties, the practice is to invoke ad-hoc advice when necessary, as was done in March, 1957, when Prof Alan Moncrieff was asked to take part in discussions which then resulted in the decision to continue Queen Mary's as a 550-bedded children's hospital This manifests the inaccuracy of Dr Lawson's statement that the Chairman of the Board refused to consider the use of expert advice, and also that the Board has never shown any serious interest in the provision of beds for pædiatrics

The Board must now proceed to examine the proposal as requested by the Ministry, but the situation will not be helped by the publication of inaccurate and intemperate statements

To seek some arbitrary standard to mark the start of the malignant phase is to betray a total misconception The malignant phase bears no direct relationship with the pressure itself A diastolic reading of 110 may be accompanied by a malignant fundus in an eclamptic young woman, while in a man of sixty a diastolic level of 150 may have produced only the earliest retinal changes

In short, the recognition of individual prognosis amongst hypertensive patients offers one of the supreme clinical challenges of the day We would do well to confess, however, that as yet the power to make this vital discrimination still largely eludes us

Victoria Hospital,
Blackpool

I McD G STEWART

ASPIRIN AND PEPTIC ULCER

SIR,—We are interested in the conclusion of Dr Flint and Dr Allibone (July 2) that aspirin, "although a gastric irritant, is a rare cause of hæmatemesis "

Since September, 1957, 40 cases of hæmatemesis or melæna were admitted to the Burnley General Hospital Each patient was questioned carefully concerning drugs taken during the week preceding the bleeding episode Close questioning was required since many patients habitually take proprietary analgesic preparations and are unaware of an aspirin content of some of these A history of aspirin ingestion within 48 hours of the bleeding was obtained in 20 cases (50%)

During the months of September, October, and November, 1957, when the influenza epidemic afflicted the community with great severity, 16 cases of hæmatemesis or melæna were admitted to this Hospital In the corresponding periods in 1952, 1953, 1954, and 1955, the numbers were 11, 16, 14, and 14 respectively Since a number of medical beds were not in use in 1956 figures for this year are excluded At the time of the epidemic the considerable publicity in the newspapers and on television advocating aspirin-containing preparations for the relief of influenza, probably resulted in a much greater consumption of aspirin than is usual at this time of year

If aspirin is to be incriminated in the production of frank gastrointestinal bleeding, one would have expected a significant increase in the incidence of hæmatemesis and melæna during the epidemic months The figures for 1957 probably represent the true incidence of hæmatemesis and melæna in this area, since the general practitioners would be more than ever likely to regard acute gastrointestinal hæmorrhage as an indication for urgent admission to hospital in view of their very heavy commitments Our experience would lend support to the conclusions of Dr Flint and Dr Allibone

WORDS AND THINGS

SIR,—When I was asked whether I had written your admirable leading article on Another Renal Symposium (Aug 2, p 247) I replied with Wilde, " I wish I'd said that," and Whistler, it is well remembered, replied, " Oh, but you will, Oscar "

Your article eloquently concludes " it is not yet certain whether some of the concepts expressed will turn out to be words ('the daughters of earth') or things— 'the sons of heaven' in the round Johnsonian phrase "

The quotation is from the preface to the English Dictionary

" I am not yet so lost in lexicography as to forget that *words are the daughters of earth, and that things are the sons of heaven* Language is only the instrument of science, and words are but the signs of ideas I wish, however, that the instrument might be less apt to decay, and that signs might be permanent, like the things which they denote "

Johnson himself was quoting, and apparently incorrectly, for Samuel Madden (1687–1765) wrote in *Boulter's Monument*, L 377 " Words are men's daughters, but God's sons are things "

I am grateful to you, Sir, for sending me back to Johnson's Preface of which Boswell wrote, " I believe there are few prose compositions in the English language that are read with more delight "

Derby

DOUGLAS HUBBLE

N H.S. STAFF COLLEGE

SIR,—Permit me to thank those correspondents who have replied to my letter either privately or in your columns

I ought to have emphasised that the college would be a meeting place for doctors and their colleagues in the service to talk about people There is no suggestion that administrators would meet administrators and talk about administration Too many exclusive coteries have already been created A new start is proposed to avoid any idea that any one section of our profession or of our lay colleagues is trying to steal a march on the rest

W S PARKER
Medical Officer of Health

HOOKWORM AND ANÆMIA

SIR,—May we make some comments on the conclusions of Dr Meiklejohn and Dr Passmore[1] ("   we suggest that a properly financed research project into the association between hookworm and anæmia is now overdue ")?

The view[2-5] that there is seldom a relation between the degree of infestation and the frequency of anæmia in a population was restated in your columns by Foy and Kondi[6] and Trowell[7] on the basis of their experience in India and in Uganda But in particular local situations of infestation, of temperature, and of humidity[8] hookworm infestation is almost constantly associated with severe anæmia, and there is also clinical and experimental evidence that the *Ancylostoma duodenale* first described by Dubini[9] in Milan in 1843 can give rise to a well-defined type of anæmia

So we agree with Foy and Kondi[6,10] that "   although hookworm may play a part in the genesis of the tropical microcytic anæmias, this is probably not a paramount one " because certainly not all the microcytic anæmias of tropical countries may be referred to *A duodenale*, or better to the worm by itself We also agree with Roche[11] that " the role of hookworm in the genesis of some tropical anæmias is probably a paramount one "

A basis for agreement may be found in the proposition that some at least of the tropical microcytic anæmias are primarily due to hookworm infestation

Why does *A duodenale* only exceptionally exert its power to produce anæmia? Recent work on pathogenesis[4,12-14] indicates that deficiency of iron is an essential factor in the production of anæmia Anæmia appears only when the hookworm is able to induce a severe iron deficiency, either by itself or with the help of other influences Without sideropenia, and whatever the degree of infestation, no anæmia develops

did not realise that Becker had listed another 33 cases under a different heading in an earlier article We regret having failed to quote all Becker's cases, but we consider the important point to be that Becker agrees that " on occasion the Bantu can and does develop just as much atherosclerosis as the European in South Africa " We consider his estimate of the incidence of apoplexy to be too low and would agree with Walker and Simson's figure [7] of 3–4% for the Bantu in Johannesburg We cannot agree with Walker's statement [12] that only 19% of Bantu show aortic atherosclerosis at necropsy

In regard to the points raised by Mr Walker and Dr Simson we omitted to mention coronary disease in our article [13] because we intend to devote two further articles to this problem An early note on our views appeared in your columns last year [14]

Much of the misunderstanding which has arisen regarding the Bantu is due to the fact that his relative freedom from myocardial infarction has been attributed to a freedom from coronary atherosclerosis It must be remembered that coronary thrombosis is only one of several manifestations of coronary-artery disease The Bantu does suffer from coronary atherosclerosis and his myocardium also suffers For example, in hypertension (a very common disease in the Bantu) Becker [11] stated " the coronary vessels are frequently diseased and the myocardium is frequently gravely damaged " And Higginson and Pepler [15], comparing Bantu with Americans and Danes, stated " our observations suggest that severe atherosclerosis of the aorta and coronary arteries are less frequent in the hospitalised Bantu of Witwatersrand than among the American and Danish hospital patients *but the differences are not conclusive* " (our italics)

HAZARDS OF CHLOROTHIAZIDE THERAPY

SIR,—I was glad to see the letter by Professor Rosenheim and Dr Ross (July 26) in which they drew attention to hazards of chlorothiazide (' Saluric ') therapy

In common with others I have often found that chlorothiazide leads to an increased loss of potassium in the urine, and the danger of a cellular deficiency of potassium developing in patients who are receiving this drug is therefore very real As is well established such depleted tissues function less efficiently In particular impaired renal function may ensue and digitalis is less well tolerated and a therapeutic dose may also be a toxic dose a potassium-depleted myocardium moreover is subject to arrhythmias Thus the maintenance of adequate digitalisation becomes more difficult and as a consequence the heart-failure may worsen [16,17]

The serum level of potassium is unreliable as an index of body content [18–20], normal or even raised levels may occur in the presence of cell deficiency Moreover, whilst it appears very likely that a low level does nevertheless indicate a cell shortage, in our experience such levels are not often found in congestive cardiac failure In a series of over 450 patients in congestive cardiac failure, under the care of Dr O Brenner, that I studied, lowering of serum-potassium was rare These patients were receiving diuretics other than chlorothiazide, but to date our experience with chlorothiazide is identical It is likely that when the serum level of potassium is low, the cellular shortage is very profound

However, I would like to reinforce their emphasis—namely, that potassium depletion cannot easily, if at all, be diagnosed in the outpatient department let alone in general practice The diagnosis cannot be made on clinical grounds, nor are there simple tests that may be performed to assess its presence

It is, therefore, necessary routinely to supplement with potassium the diet of every patient having chlorothiazide A supplement of about 60 mEq per day is adequate But potassium salts are unpleasant to take and may occasion nausea, vomiting, &c [21] This must be appreciated since there is a real possibility of patients discontinuing their supplements unknown to the doctor It is helpful, in this connection, to see which of the many salts of potassium that may be given are most acceptable to each patient I have used potassium chloride, potassium bicarbonate, potassium dihydrogen phosphate, dipotassium hydrogen phosphate, potassium citrate, and potassium effervescens * Other salts have been used in hospital practice, but cannot be obtained easily in general practice These salts are best taken in solution and the tablets of potassium effervescens may be dissolved in water I have found it helpful to give potassium chloride in concentrated grapefruit juice The amount of each of these supplements to contain approximately 60 mEq of potassium is as follows

Potassium supplement	*Amount containing 60 mEq.K (approx)*
Potassium chloride	4 2 g
Potassium bicarbonate	6 6 g
Potassium dihydrogen phosphate	8 2 g
Dipotassium hydrogen phosphate	5 2 g
Potassium citrate	6 5 g
Potassium effervescens †	22 tablets

DIASTOLIC PRESSURE AND MALIGNANT HYPERTENSION

SIR,—In his letter of July 26 Dr Cruz-Coke maintains that by measuring diastolic blood-pressure levels against a standard scale, adjusted for age and sex, it is " possible to identify patients with malignant hypertension before changes are evident in the fundus and before left ventricular hypertrophy develops It also allows the significance of high blood-pressure to be assessed in old people "

These are large claims If we could learn to pick out in advance those patients in whom hypertension will sooner or later go to the bad, in consequence of fatal or disabling vascular damage, we could then treat them with the new autonomic paralysing drugs in the assurance that we should be doing much to avert their destined fate

Unfortunately the criteria suggested by Dr Cruz-Coke are not enough We all know that raised arterial pressure in a young man presents a threat much more serious than the same pressure in an old lady But we still can foretell very little of individual fortune among the members of parallel groups We know, for example, that out of 10 fifty-year-old men with diastolic pressures of 130 mm Hg 2 or 3 will probably be dead in a year or so of strokes, heart-failure, or malignant renal change But we do not know which 3 Another 2 or 3 may very well survive into old age Again we are unable to identify the lucky ones And Dr Cruz-Coke's tables cannot help us

Nevertheless we can bear in mind some points that will enable us to make a rough selection This, in fact, is what we do, almost subconsciously, when we first assess a new patient with hypertension Together with age and sex we certainly consider also the factors of heredity, lability of pressure, and the trend over a period adopted by its resting level, with a

Granulated on a hot plate

We should like to draw attention to the following features

(1) Without exception the psychotic reactions occurred in a labile premorbid personality with strong emotional conflicts preceding the onset of the psychosis In 2 of the cases physical exhaustion was also present.

(2) Physical and neurological examinations including lumbar puncture did not reveal any abnormalities Repeated electroencephalography gave a normal record in 3 patients The tracings of the 4th were abnormal, but inconclusive Therefore, we failed to demonstrate clinical or electroencephalographic evidence of a correlation between the acute psychosis and a presumptive encephalitis

(3) 3 of the 4 patients were young people under 17 The clinical picture was characterised by a confusional state with psychomotor restlessness, delusions, visual hallucinations, and aggressiveness The acute psychotic symptoms cleared spontaneously on the average within two weeks A short-term relapse of the psychotic incident was observed in a single case whose final outcome was also favourable

(4) On the psychodiagnostic level all patients were found to be of normal intelligence with clear evidence of a disturbance of mental equilibrium No support could be found for the assumption of structural damage to the brain, nor of an acute manifestation of a latent psychosis, with the illness in the role of a trigger Rather do we incline to interpret the psychotic episode as the reaction of a personality lacking full integration, maturity, and flexibility to the disturbance of somatopsychic homœostasis caused by the attack of influenza

NO MORE NEOLOGISMS?

Sir,—Why not "No More New Words?"?

Chesham, Bucks FFRANGCON ROBERTS

Sir,—In reply to the letters by Dr Pappworth and myself (July 26) you rightly emphasise that an editor has a duty to his contributors, and thus you justify the use of new words which we think are often unnecessary and nearly always serve to obscure But, Sir, has not an editor a duty to his readers, and is it not important that the reader should understand what the writer is trying to say? If the reader cannot understand, why should the author bother to write, or the journal to print, the paper?

You allude to the centenary of the hypothesis of natural selection If I remember rightly, the key to that hypothesis was the elimination of the unfit In this context the unfit are words, and our plea is that the unfit should be eliminated by editorial action.

Oxford. GEORGE PICKERING

"EXPERIENCE AND INCENTIVE" AWARDS?

Sir,—I have read Dr Evans' letter last week with interest, but I would like to suggest a more practical basis for administering awards for meritorious work in general practice

The doctor would apply to the awarding authorities in confidence, giving specified credentials such as 7 to 8 years in general practice (at least 5 as a principal) and a National Health Service list above an accepted minimum varying with districts The censors would then visit him (one hopes unexpectedly) and inspect, they would demand a definite standard of work, surgery premises, equipment, organisation, and note-taking Another censor would sit in during a surgery (this time by arrangement), a third would go on visits with him, and yet another (one hopes over coffee) sound him out to see that his basic medicine is still intact, and that he has made attempts to keep up to date If there is a doctor able to stand up to all this, then he is worthy of the encouragement of an award, and even our most modest colleagues might come forward if they knew that their recognition would in honour bound be kept silent

Who would our censors be? Presumably they would be chosen from our most capable practitioners, stiffened by consultants with examining experience It would be understood that our regional examiners would never examine within their own areas

There is one plea I would put forward, and that is that if a doctor fail to reach the required standard he should be told why, and permitted to reapply after a suitable interval without prejudice

London, S.E.3 L I NORMAN

CONGENITAL FIBROELASTOSIS OF THE ENDOCARDIUM, NUTRITIONAL HEART-DISEASE, AND MYOCARDIOPATHY OF UNKNOWN ORIGIN

Sir,—Johnson[1] suggested that congenital endocardial fibroelastosis is caused by anoxia of the endocardium One mechanism by which this may occur is premature closure of the foramen ovale which prevents blood circulating through the left side of the heart in utero Since the endocardium derives its blood-supply from the blood within the heart chamber it is the site that is predominantly affected It would seem reasonable to consider, therefore, whether anoxia could play any part in the production of endocardial fibrosis of adults

One way in which this could occur would be stagnation anoxia of the blood within the heart chambers It is characteristic of so-called nutritional hearts that they are markedly dilated and pulsate so poorly that they resemble pericardial effusions In such a quiet heart stagnation of blood might well be expected to occur Furthermore, one would expect the site most severely affected to be the apex of the ventricle, and this is where the earliest signs of fibroelastosis are usually found

Two investigations would help to clarify the part played by such a mechanism Retrograde aortic catheterisation could compare the oxygen saturation levels of blood samples taken from the aorta and from the region of the apex of the left ventricle Angiocardiography could demonstrate incomplete emptying of the heart in systole, and how long the opaque material stagnates within the ventricles

It could be contended that all dilated hearts should show a similar change This is not necessarily so, because cardiomegaly from other causes is not usually associated with the quiet almost motionless heart seen in nutritional heart-disease and myocardiopathy of unknown origin. Active contractions, even if not associated with complete emptying of the heart chamber in systole, may be enough to maintain a turbulence that prevents a layer of stagnant blood forming over the endocardium

If stagnation anoxia is a significant factor then fibroelastosis and thrombosis become secondary changes The primary disturbance would be cardiac dilatation, the cause of which remains obscure. Such an explanation would serve to bring these myocardiopathies into much

---

[1] *Arch Path* 1952, 54, 237

What are the morphological and biochemical characters of anæmia induced by hookworm? Hookworm produces a typical iron-deficiency anæmia In this conclusion we agree with all who have studied the disease in Italy [15–19] or in other countries (Jugoslavia,[20] France,[21] Portugal,[22] Egypt,[23] Guadalupe,[24] Japan,[25] Brazil [4,26] Of course when other factors are present—either internal (deficiency in production of intrinsic factor, changes in intestinal bacterial flora, production of *infection or infestation, hepatosplenic abnormalities, &c*) or external (deficiencies in B^{12} and folic acid in the diet)—the anæmia may differ from pure iron-deficiency anæmia Though such associations are common in tropical countries, they are exceptional in Europe where ancylostome anæmia is usually of classical iron-deficiency type

Our study of more than 100 anæmic patients brought out these features of hookworm anæmia

(1) Microcytic hypochromic anæmia with red hyperplasia of the bone-marrow caused by inhibition of maturation in the erythropoietic tissue [13,14]

(2) Hyposideræmia (serum-iron under 50 µg per 100 ml) [13,18] hypertransferrinæmia (plasma-transferrin above 350 µg per 100 ml [13,27]), and hyperprotoporphyrinoglobulia (free-erythrocyte-protoporphyrin-9 above 100 µg per 100 ml) [13,28,29]

(3) Intravenous ^{59}Fe is distributed in the typical "iron-deficiency pattern" [14,30]

(4) Constant and quick response to iron therapy [13,14]

Our investigations into other possible ways in which anæmia could be produced, such as excess hæmolysis, or bone-marrow inhibition by hookworm toxins, have clearly shown that hookworm anæmia [13,14] is not determined in any of these ways

The correction of the anæmia by the simple administration of iron, while infestation is still present, is the chief evidence that the anæmia depends exclusively on iron deficiency

The most important question is how the hookworm induces iron deficiency Hookworm may impair the normal gastroduodenal processes by which food iron is dissolved and ionised [14,30] It may also interfere with iron absorption by the duodenal and jejunal mucosa [14,30] *A duodenale* also increases the elimination of iron from the gut by bleeding from mucosal lesions Basing our opinion on our experience with the radioactive method of Gerritsen et al [31] we believe that, *though hæmorrhage, and consequent loss of iron is* very important in the genesis of the sideropenia, hæmorrhage cannot by itself explain all the anæmias in those infested by parasites Severe anæmia may develop in patients with slight blood-loss, and some men with ancylostomiasis may lose about 10–20 ml of blood a day without becoming anæmic

The effect of hookworm may be enhanced by a diet extremely poor in iron or by a diet abnormal in calcium and phosphorus content Such an alimentary factor is of very little significance in Italy and probably in other European countries In other parts of the world, however, [4,32] it is of fundamental importance in the production of iron deficiency The size of iron stores is also relevant, and the exhaustion of these reserves, the first step in the development of anæmia is obviously more easily accomplished in patients with initially low reserves

It is usually a combination of these factors, and not one alone, that explains the development of anæmia in ancylostomiasis We conclude that hookworm anæmia is a real well-defined clinical entity due to iron deficiency induced by worm infestation

SHOULD BIBLIOGRAPHIES GIVE TITLES OF PAPERS?

SIR,—Mr Patey (July 19) has expressed what is a growing concern at the wilfulness of British publishers in not allowing their contributors to provide the title of papers in their references In your own case, the argument is perfectly valid—they would replace a short article *In other journals, and in many English books, the same* practice prevails even when half a page is left blank at the end of an article or a chapter

Now that "the English literature" enjoys a prestige as great as that of "Eng Lit" it is surely mandatory that *it should* be given a final veneer of completeness I suggest, therefore, that *The Lancet* makes the gesture—how I cannot suggest Pressed as you are for space, it is a question of quality versus quantity

REAPPEARANCE OF TABOPARESIS

SIR,—I have just returned from a two months' guest lectureship in Munich, and I can confirm Dr Noel Harris' remarks (Aug 9) from my observations at the Universitaets-Nervenklinik At least four recent cases of general paresis of the insane were admitted during my presence Syphilis of the central nervous system had apparently not become as rare in the large German cities as it was here, but the recent increase in patients suffering from taboparesis has been noticeable It was thought to be due to the turmoil and strife of populations in Europe after the late war when treatment of venereal disease was inadequate or lacking

W MAYER-GROSS

NEUROLOGICAL COMPLICATIONS OF ASIAN INFLUENZA

SIR,—In your issue of July 5 you published four interesting papers dealing with the neuropsychiatric complications of Asian influenza In your accompanying annotation you state that psychotic outbursts related to influenza "are a symptom of encephalitis and do not represent a latent psychosis which has been revealed by a generalised infection"

Following the epidemic of Asian influenza in Israel during November and December, 1957, 4 patients who developed psychotic manifestations during the course of the influenzal illness were admitted to Talbieh Psychiatric Hospital, Jerusalem The psychosis appeared in 3 of the cases within three days of the onset of the influenza The correlation between the *development* of the psychosis and recent infection was ascertained by a progressive rise in titre of the hæmoagglutination inhibition for the Asian virus variety during the psychotic outburst (A detailed report of our cases was recently published in *Dapim Refuim*, Israel, 1958)

to interfere with his everyday life and work His cheerily shouted ‘ hullo ’ used to echo round the blocks as he made his daily visits Only a week before his death he attended the staff club’s horticultural show and made one of those speeches which were always so apt and for which he had a justified reputation Staff and patients alike have lost a real friend.

“ For the last twelve months of his life he held the posts of master of the Worshipful Company of Girdlers and renter warden of the Worshipful Company of Inn Holders The former office was held by his late father thirty years earlier He was unmarried, and in all his work he enjoyed the active interest and support of his mother ”

WILLIAM HENRY CASSWELL SPOONER

M.B Lond

Dr W H C Spooner, of Blandford, Dorset, was drowned at Brest on Aug 1 when his yacht *Remarie* was rammed and sunk at her moorings by a tug His wife and three children, who had joined him a few hours earlier, escaped

He was educated at Epsom College and qualified from St Mary’s Hospital in 1932 After holding house-appointments at St Mary’s and at St James’ Hospital, Balham, and an assistantship in North Wales, he went into practice at Blandford, where his greatgrandfather, grandfather, and father had practised before him. During the late war he served in the Royal Air Force

R Mac K writes

“ Spooner was very modest about himself but he was a very good doctor indeed He looked forward all the year to his summer holiday, for the last ten years he took his family cruising in *Remarie* on the Brittany coast. ‘ Skip ’ was a good navigator and knew the coast well Often his was the only yacht among the fishing boats in the anchorage Last week when, after a week with two companions, he reached Abervrach, he said he was happy to be back on this coast He was a good painter in water colours and oils and played a great part in the Forum Club at which professional and amateur artists of Dorset met at Blandford. He was an excellent host Conservative in his outlook, he was open-minded and could admire the Teddy boys for the originality of their dress Perhaps this was just an illustration of his most thoughtful and courteous way with every one of us He will be very much missed and not only in Dorset ”

A memorial service for Sir Arnold Stott will be held in Westminster Hospital’s Chapel at noon on Thursday, Sept. 25

Notes and News

ACCIDENTS TO CHILDREN

ACCIDENTS have now become the leading cause of death among children both in the United States and in Europe At a seminar held at Spa last month by the World Health Organisation it was pointed out that children must not be overprotected, and should be taught to cope with dangerous situations, but at the same time unnecessary dangers should be removed.

In different countries the prevailing risks differ Drowning is particularly frequent in Scandinavia, the Netherlands, and France In Spain, small children lose their lives or are seriously injured by falling into open braziers—a danger that is gradually disappearing as housing is modernised “ A similar problem exists in the British Isles, where the open fireplace is the usual way of heating the home ” In Italy and Poland, damage from explosives left from the last war is a prominent hazard, which vigorous propaganda has done much to reduce Poisoning of young children is common in the U S.A , Switzerland, and Sweden—countries where many chemicals are to be found in the home Suffocation of small children who, while playing, put their head into a plastic bag is reported as a real danger in France, Belgium, Denmark, and Sweden

“ Small children do not understand dangers and must be protected from them, particularly from life-threatening hazards, but as they grow older they must be taught to cope with dangerous situations They must learn to climb, to jump and to fall, to handle knives, forks and scissors, to swim, to use matches and understand fire, to get along in traffic. The wise parent will thus protect the child as far as ever possible from dangers from which the child can learn nothing and not worry about small accidents from which the child can learn how to avoid them It is through this positive approach combined with the elimination of deadly hazards from the environment of the child that it will be possible to reduce the number of accidents ”

ROYAL MEDICAL BENEVOLENT FUND

DURING 1957 this Fund disbursed £43,942 in grants and annuities The number of cases (398) helped by grants was almost the same as in the previous year, but the grants rose by £2599 Though the number of annuitants decreased by 6, annuities amounting to £12,406 (£455 more than in 1956) were distributed. “ This increase in the amount of grants and annuities to approximately the same number of beneficiaries appears to reflect the rise in the cost of living, and the Rent Act, of course, has made its expected impact This may well become more pronounced in 1958 ” The number of people who benefit is much larger than the number of cases quoted Many of these include married couples, children requiring sustenance and education, and widows with families

In his report for the committee of management, Dr T Anwyl-Davies, the hon secretary, asks for more help in meeting demands which, in spite of the Welfare State, are ever expanding

“ To increase our income, new subscribers are essential We are very grateful to those who subscribe annually and we appeal to them to suggest to their colleagues that they might wish to do likewise Surprisingly enough, many of the profession do not know of its existence or of its work. Many gladly subscribe when their attention is drawn to its purpose of acting as a Good Samaritan to the whole of the medical profession The Fund gives assistance to distressed members of the profession, their wives, widows and children Immediate help is given in urgent cases and all deserving applicants are treated impartially ”

Dr Anwyl-Davies appeals to subscribers, new and old “ to consider the very profitable and simple procedure of signing seven-year covenants ” Some 1275 already subscribe by covenant and last year £5845 was recovered, without further cost to the “ covenanted ” subscribers, from the Inland Revenue He also thanks those who remember the Fund in their wills—however small the legacy may be “ Last year the legacies received came to the welcome sum of £29,495, a very valuable addition to the accumulated funds ”

The report for 1956 mentioned that under the Giffen bequest a house was to be bought and equipped for indigent doctors A large closer alignment and explain why in some cases there is neither fibrosis nor thrombosis

Furthermore, support for some common factor may be found in Bedford and Konstam's[2] account of the postmortem findings in adult Africans dying of heart-failure of unknown ætiology Of 17 of these cases 3 had hypoplasia of the aorta, which is known to be associated with congenital fibroelastosis of the endocardium

INTRADERMAL TESTS FOR SERUM SENSITIVITY

SIR,—We are in full agreement with Dr Tasman and his associates[3] regarding the superiority of the intravenous route over the intramuscular in the antitoxin treatment of diphtheria, but we do think that it is an exaggeration of good therapy to advocate that route for all cases however mild and even for all suspected cases

We differ entirely from them, however, regarding the value of intradermal reactions of any kind as a means of detecting general sensitivity to serum They quote our article[4] of 1957, but do not mention a previous one[5] dealing with the subject generally and not only in connection with tetanus antitoxin administration We would refer them to that article

We both know of instances of severe allergic shock, some of them fatal, which have occurred following antitoxic serum given either intramuscularly or intravenously on the strength of a negative skin test On the other hand, one of us (L J M L) has had experience (in the course of titration of scarlatinal antitoxin on scarlet fever patients) of more than 50 cases, with strongly positive intradermal reactions to serum in a dilution of 1 in 10, but no general reactions whatsoever when given a full dose of scarlatinal antitoxin intramuscularly a few hours later Moreover, many of these patients still had positive skin tests when there could be no more question of general sensitivity remaining We have come to the conclusion—and many of our colleagues in various hospitals have, too—*that skin sensitivity and general sensitivity do not run parallel*

Since skin tests have proved so unreliable, we have used and recommended for years the method of a small trial dose of 0 2 ml of undiluted or diluted serum given subcutaneously for the purpose of detecting *general* sensitivity This method may, on rare occasions, cause allergic shock in hypersensitive patients, but owing to the small dose and the slow absorption this shock can be quickly controlled

ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND

SIR,—I am grateful to you for allowing me to use this opportunity of bringing to the notice of the profession that the College is holding its annual meeting this year on Sept 26 and 27 in Cardiff

As you know, the College has recently adopted the policy of holding meetings from time to time in provincial centres, and the first of these was held in Manchester in 1955 The purpose of the council in holding these meetings is to bring the College closer to its provincial Fellows and Members and to enable them to take part in some of its activities The council is particularly anxious that Members of the College shall join us at this meeting, and any other diplomates will of course be very welcome Fellows have already been notified individually

The meeting will consist of a reception at Cardiff Castle, kindly given by the Lord Mayor and Council of Cardiff, and a subscription dinner, both on Friday, Sept 26 Tickets for the dinner (two guineas each) and invitations for the reception can be obtained from the Secretary of the College, but the numbers for both events are limited and early application is necessary

On Saturday, Sept 27, the morning will be devoted to scientific exhibitions and surgical operations arranged by the local committee at the Cardiff Royal Infirmary, followed by a fork lunch, kindly given by the Board of Governors of the United Cardiff Hospitals

In the afternoon, at 2 30 P M, the statutory annual meeting of Fellows and Members will be held in the Reardon Smith Hall, and this will be followed by the conferment of the Honorary Fellowship of the College on Sir Russell Brain, Bt, who will afterwards deliver a lecture on The Cervical Spine

The council hopes that this meeting will prove to be as successful an event as was the meeting in Manchester, and we trust that our colleagues in Wales will make a special effort to attend

Royal College of Surgeons of England,

J PATERSON ROSS

Obituary

JOHN BROCK BISHOP

M A, B M Oxon, T D

Dr J B Bishop, deputy superintendent of Broadmoor Institution, died at his home on Broadmoor Estate on Aug 4, at the age of 50

He was a scholar at the Merchant Taylors' School and later an exhibitioner at St John's College, Oxford, where he took his preclinical course, gaining second-class honours in physiology His clinical work was done at St Thomas's Hospital, London, and after qualifying in 1931 he served there as casualty officer and house-physician Later he was a clinical assistant at the West End Hospital for Nervous Disorders and house-physician at the Victoria Hospital for Children Until 1939 he was in private practice in Chelsea During the late war he served in the R A M C both at home and overseas in North Africa and Italy He was mentioned in despatches and received the Territorial Decoration with there bars After the war he continued to serve in a hospital ship He remained a keen member of the Territorials until his transfer to the Army Emergency Reserve He went to his last camp only a few weeks ago

In 1948 he joined the staff of Broadmoor, where he worked first as a medical officer and later as deputy superintendent From the outset he regarded this as his life's work Of these years V G S writes

" Brock Bishop's main interest professionally was not in the science but in the art of medicine and its social applications The organisation at Broadmoor gave him wide scope for his particular type of work, and his practical common sense was an invaluable asset in such an institution For two years he sustained practically the whole administration of the institution during the illness of the late Dr S G James, then medical superintendent

" For some years he was handicapped by a neurological condition which with his characteristic tenacity he forbade

GLANDULAR TOXOPLASMOSIS

A SURVEY OF 30 CASES

J K A Beverley
M D B Sc Sheff,
LECTURER IN BACTERIOLOGY
C P Beattie
M A, M B Edin, D P H
PROFESSOR OF BACTERIOLOGY
UNIVERSITY OF SHEFFIELD

IF the results of toxoplasma antibody surveys are to be believed—and there is at present no valid reason to doubt them (Cathie 1957, Feldman and Miller 1956)—subclinical toxoplasma infection is common in this country, as in others. A recent survey in Lincolnshire (Beattie 1957) showed that 36% of country-dwellers and 22% of town-dwellers had cytoplasm-modifying (dye test) antibodies (Sabin and Feldman 1948) to a titre of 1/16 or more.

By contrast, clinical manifestations of toxoplasma infection appear to be uncommon, but perhaps they are not so uncommon as is often thought.

In the two toxoplasma reference laboratories in London and Sheffield in 1950–56 congenital toxoplasmosis was diagnosed by serological and in some cases animal-inoculation methods in 110 cases, and probably many more went undiagnosed (Beattie 1957). Moreover it is estimated that from 20% to 35% of choroidoretinitis is due to toxoplasma infection, mostly congenital (Smith and Ashton 1955, Jacobs et al. 1956, Perkins and Beverley 1958).

Infection cannot all be congenital. Nor would one expect that the manifestations of acquired infection should always, as in the earlier reports, be severe. For these reasons Siim (1951) looked for evidence of toxoplasma infection in patients with fever of unknown origin. He found it, as did Gard and Magnusson (1951) and von Zeipel and Linder (1951), in patients with lymphadenopathy resembling "glandular fever." These results were confirmed in this country by Skipper, Beverley, and Beattie (1954), by Cathie (1954 a and b), and by Bateman (1957). In Denmark Siim (1956a) has encountered over a hundred such cases. He estimates that toxoplasmosis accounts for about 5% of cases of lymphadenopathy of unknown origin. In our experience it accounts for about 7% of cases clinically diagnosed as "glandular fever" but giving a negative Paul-Bunnell reaction.

The Present Series

The purpose of this paper is to direct attention to this glandular form of toxoplasmosis, which appears to be the commonest manifestation of acquired infection. Thirty cases are prescribed in summary form (table I), and the results of antibody studies on the relatives of some of the patients are shown (table II). Some of the cases have been reported already and others will be reported more fully elsewhere.

Discussion

It may well be asked how a diagnosis of toxoplasmosis can be made and on what basis the cases were selected for this report. Isolation of the parasite by animal inoculation is the most trustworthy method.

In cases 7, 11, 14, and 19 the diagnosis was confirmed by inoculation of ground-up gland material into mice. In cases 24, 25, and 29, this failed. Toxoplasms have been isolated by other workers from muscle taken by biopsy, from tonsils, from blood, and from saliva. We failed to isolate toxoplasms from the tonsils of patient 18, but the attempt was made 8 months after the start of her illness, and we also failed to isolate the parasites from the blood or saliva of patients 19 and 20. It should be noted that, as in the present instances, toxoplasms from man often prove of low virulence for, and fail to produce obvious illness in, laboratory animals, yet toxoplasma cysts may be found in their brains a month or more after inoculation.

Rarely is it possible to make the diagnosis by demonstrating the parasite in excised lymph-glands. Indeed this has only once been done with certainty, when Stanton and Pinkerton (1953) after long search found one cyst. This is the only form which can be definitely identified in tissue sections. Nor can the histological picture establish the diagnosis, though it may suggest it.

The morphological changes in lymph-nodes have been described by Stanton and Pinkerton (1953), Siim (1952), Lelong et al. (1954), and Bang (1957). From these accounts it might appear that there is little agreement as to the actual microscopical changes, but this is probably due more to lack of unanimity in nomenclature than to true histological differences. In most cases there is a reactive hyperplasia with scattered foci of histiocytic or epithelioid cells.

Robb-Smith kindly examined sections of glands from some of the patients in this series and reported that those from patients 10, 11, 15, 17, 19, 21, 22, 23, and 24 correspond with his description of "lymphohistiocytic medullary reticulosis" (Robb-Smith 1947). The glands from patients 7 and 25 were not so typical of this. He found a similar appearance in sections of lymph-glands submitted to him by Siim and Bang, who described the change (1957) as a focal medullary reticulosis. The reaction, although characteristic, is not specific. Robb-Smith has found it in kala-azar and in many cases of unexplained ætiology which until recently were not investigated serologically for evidence of toxoplasmosis. It is distinct from the appearances found in infectious mononucleosis with a positive Paul-Bunnell reaction. Recently sera from six patients have been sent to us for serological tests for toxoplasmosis because a histological diagnosis of lymphohistiocytic medullary reticulosis had previously been made. Two of them proved strongly positive (cases 10 and 15). A third was very suggestive (dye test 1/256 but negative complement-fixation test), while the remaining three gave only low titres.

As animal-inoculation methods are not always possible or successful, the diagnosis must often rest on serological tests. Those now in use are the complement-fixation test and the cytoplasm-modifying (dye) test. An important but difficult question is what titres should be taken to signify active infection.

One answer would be to accept titres above those found in the normal population. We have recently found (unpublished) that only 2 out of 1357 adult blood-donors had dye-test titres of 1/256 or more. That titre, in the presence of a clinical picture compatible with toxoplasmosis, might be accepted. Another answer would be to accept titres comparable to those found in persons from whom toxoplasms were isolated. In the present series that would mean dye-test titres of 1/1000 or more, and indeed in twenty-five of the cases here reported the titres are, or are nearly, of this order. On the other hand Jacobs et al. (1954) isolated toxoplasma from the eye of a patient whose dye-test titre before enucleation was 1/64, Prior et al. (1953) from the blood of a healthy young woman (owner of a toxoplasma-infected dog) whose dye-test titre was 1/160, and we ourselves (unpublished) from the ventricular fluid of a baby whose dye-test titre was 1/170 and whose complement-fixation titre was less than 1/5. Sabin et al. (1952) suggest that for proof of active infection the dye-test titre should increase eightfold or more to at least 1/256 and be maintained at or near that level for several weeks. During this time house in Putney is now to be converted into five self-contained flats each consisting of a bedroom, sitting-room, bathroom, and kitchen

During the year the Ladies' Guild distributed more than £13,000 This auxiliary helps with visiting, the education of children, the care of young widows, and the distribution of medical comforts, gifts of clothing, coal and other necessities Parcels of clothing, with the donor's name and address inside, should be sent to the clothes room, Ladies' Guild of the R M B F, Tavistock House (North), Tavistock Square, London, W C 1

At the annual general meeting on July 30 Sir Henry Tidy was re-elected president, Mr F A Juler hon treasurer, and Dr Anwyl Davies hon secretary The Fund's address is 1, Balliol House, Manor Fields, Putney, London, S W 15

THE BIRMINGHAM DENTAL HOSPITAL

The year 1958 is celebrated for many important centenaries in medicine, including that of this unique hospital—unique because it is the oldest dental institution in this country and possibly in the world

It was Samuel Adams Parker, a son of Langston Parker, the famous surgeon on the staff of the Queen's Hospital, who founded the Birmingham Dental Dispensary early in 1858 when he had but recently finished his dental studies at the Middlesex Hospital The first premises were at 13, Temple Street, and it is interesting that the committee set out to undertake not only extractions but also stoppings and scalings as well as "the regulation of children's teeth" C J Fox had in 1855 opened a similar dispensary in London, but it was not to last long The Birmingham Dental Dispensary, on the other hand, prospered and had already moved premises twice before the passing of the Dental Act in 1878 Its more active concern with teaching necessitated in 1882 a third move, this time to 71, New Hall Street When in 1900 Mason's College became the University of Birmingham, another move was soon required, and in 1905 the hospital occupied its present site which it has more than outgrown A fifth move, we hope, will not be delayed long

Mr R A Cohen has gone to great pains in preparing a history of the hospital[1] writing of the many devoted people who have served it so well in this hundred years

University of Oxford

On Aug 2 the following degrees were conferred

D M—G A Rose
B M—M A Pratelli

Shortage of Staff at York

Owing to shortage of junior staff in the surgical departments of York hospitals, admission to the surgical wards has been restricted (*Yorkshire Post*, July 30) At a meeting of the York "A" and Tadcaster Hospital Management Committee the secretary said there should be five house-surgeons at the city, county, and military hospitals, but in fact there was only one, which was not enough for proper supervision of the wards The consultant staff had therefore agreed for the time being to admit only emergency cases, urgent cases from the waiting-list, and some minor cases which would not need much supervision At the York Maternity Hospital, owing to a shortage of nurses, only one ward is being used

Future Role of the Special Hospitals

When he opened a £100,000 ward block at the Royal Orthopaedic Hospital, at Northfields, near Birmingham, on Aug 2, Sir Harry Platt said that there was a powerful school of thought whose adherents held that the day of special hospitals was over This was doubtless true of small special hospitals, situated in isolation and unable to share in the diagnostic facilities of the modern general hospital He was one who believed that a limited number of large special institutions would be needed for many years to come But such institutions must "justify their continued existence not only by providing for long-stay patients a comprehensive range of rehabilitation facilities, but must, under the guidance of the university medical schools, become centres of research and teaching"

Medical Research Council

The Council announce that they have made the following travelling awards for 1958–59

Rockefeller fellowship in medicine—Dr G Burnstock, research assistant, department of pharmacology, University of Oxford, Mr P J Holloway, external scientific staff member, M R C Laboratories, Hampstead, Mr W B Jennett, lecturer in neurosurgery, University of Manchester, Dr A P Mathias, lecturer in biochemistry, University College, London, Dr R P Michael, clinical research fellow, department of experimental neuroendocrinology, Institute of Psychiatry, Maudsley Hospital, London, Dr P H A Sneath, scientific staff member, National Institute for Medical Research, Mill Hill, London

Lederle fellowship in medicine—Dr R J Linden, lecturer in physiology, University of Leeds

Alexander Pigott Wernher fellowship in ophthalmology and otology—Dr G B Arden, research assistant, Institute of Ophthalmology, London

French exchange scholarships in medical science—Miss J E Cremer, scientific staff member, M R C, toxicology research unit, Carshalton, Surrey, Miss S Reiman, assistant lecturer in psychology, Institute of Psychiatry, Maudsley Hospital, London

The following awards have been made after nomination by the Council

Lilly fellowships in medicine—Mr J D Griffiths, senior registrar in surgery, St Bartholomew's Hospital, London, Dr C W M Wilson, lecturer in pharmacology and therapeutics, University of Liverpool

United States Public Health Service, National Institutes of Health, Bethesda, Maryland, fellowships in medical science—Dr B S Hartley, research fellow, department of biochemistry, University of Cambridge, Dr K W Cross, reader in physiology, St Mary's Hospital Medical School, London, Dr A Doig, medical registrar, Royal Infirmary, Edinburgh

Social Security Agreement with Yugoslavia

The convention on social security between the United Kingdom and Yugoslavia, which was signed on May 24, has now been ratified and will come into force on Sept 1 The convention covers cash benefits for unemployment, sickness, maternity, old age, widowhood, orphanhood, industrial accidents and diseases, death, and family allowances

Licence of Ravensburg Doctor Withdrawn

The Schleswig-Holstein Minister of the Interior has withdrawn the medical licence of Dr Herta Oberheuser At the annual representative meeting of the British Medical Association (see *Lancet*, July 19, 1958, p 148) a resolution was passed expressing distress that a doctor who had been convicted of medical war crimes should be allowed to return to medical practice

More Psychiatrists for Birmingham

On the recommendation of their consultant services committee Birmingham Regional Hospital Board have agreed to the appointment of 12 additional consultant psychiatrists in the region (*Birmingham Post*, July 24) Subject to the approval of the Ministry of Health, it is intended to fill 3 of the posts immediately The committee believe that it would be impossible to fill all 12 posts at once

Dr P H C Fowell has left the residue of his estate, almost £30,000, to the Imperial Cancer Research Fund

Surgeon Commander J Alexander, R N V R, has been awarded the Royal Naval and Royal Marine Forces Volunteer Reserve decoration

Surgeon Captain W P E McIntyre is to be promoted surgeon rear-admiral in November when he will succeed Surgeon Rear-Admiral R L G Proctor as deputy medical director-general of the Navy

Dr J T Hayward-Butt has been appointed assistant professor of anæsthesiology at the State University of Iowa

Dr M B McIlroy has been appointed an associate professor of medicine in the University of California

The Royal Society has awarded a Mr and Mrs John Jaffé donation studentship to Dr Jennifer Wildy to work on the biosynthesis of the protein and hæm components of hæmoglobin in the department of chemical pathology of University College Hospital Medical School really ill, and one (30) admitted to no more than having felt "off colour" The shortest duration was 1 week (patient 4) and the longest at least 44 weeks (patient 25) In general, adults and adolescents were more severely affected than children

---

[1] The History of the Birmingham Dental Hospital and Dental School By R A COHEN L D S, F S A Published by the Board of Governors of the United Birmingham Hospitals

Among the first things noticed by twenty of the thirty patients, or by their parents, was swelling or pain in lymph-glands, usually in the neck In five cases (7, 11, 14, 16, 17) so little account was taken of this that 2–8 weeks passed before a doctor was consulted

Any group of neck glands may be affected Sometimes the enlargement was unilateral and sometimes bilateral In addition to glands in the neck, the axillary and inguinal glands were usually enlarged, and in three patients glands in the chest wall In one patient (8) X-ray examination revealed enlargement of hilar glands The size of the glands varied from 1 to 6 cm Some were soft, some rubbery, and some hard They were discrete and not attached to the skin In five patients (3, 8, 22, 24, 25) they were tender, patient 3 cried with pain, and the first symptom noted by patient 19 was glandular aching But in most cases tenderness, if present, was slight The glands as a rule took a long time, sometimes many months, to return to normal size

Sore throat was not a prominent symptom It was noted at the start in seven patients and developed later in three others Other first symptoms were headache, fatigue, depression, and muscle pain None of the patients had a high fever and eleven were afebrile The spleen was enlarged in five patients in two of whom the liver was also enlarged Siim (1956a) states that the spleen is seldom palpable

The patient whose initial symptom was headache (24) had also pain in the back and neck which led to a suspicion of poliomyelitis Three others developed headache during their illness (20, 25, 26), and patient 26 was suspected of having meningismus Here, perhaps, may be seen a transitional stage towards the rare severe cases of toxoplasmic encephalitis

Pain in the joints and limbs was experienced by three patients (19, 24, and 25) and has been observed by Stanton and Pinkerton (1953) and by Garin (1953)

Abdominal pain was present in three (19, 23, 25), from one of whom (19) an apparently normal appendix was removed It seems possible that toxoplasmosis may cause mesenteric adenitis

* Toxoplasma recovered from gland by mouse inoculation † Reported in greater detail by Beverley et al (1958) ‡ Reported in greater detail by Paton et al (1958)
C.F T = complement-fixation test Sl. = slight.

the level of the complement-fixing antibody should either change from negative to positive and rise to a titre of 1/8, or, if positive initially, should subsequently increase at least fourfold A rise in titre is of great value, but repeat specimens cannot always be obtained Moreover the antibody titre may be at its highest when the first specimen is taken

For this report we have adopted an arbitrary level of a dye-test titre of 1/256 and a complement-fixation titre of 1/10 *This does not prove toxoplasmosis but makes it* very highly probable We have departed from this in only two cases—in case 2 because the rise in dye-test titre seems to justify inclusion and in case 4 because the dye-test titre was 1/875 though the complement-fixation titre was only 1/4 The titres chosen have meant the regretted omission of numerous other cases believed to be toxoplasmosis, some of which will be mentioned later

It should be noted that titres may not reach the arbitrary level till some time after the onset of symptoms After laboratory accidents, when the development of toxoplasmosis was expected and the onset of symptoms looked for, the interval has been 1–4 weeks

It was hoped that a study of the case-records would show characteristic features which would enable glandular toxoplasmosis to be diagnosed clinically, but it has not done so The diagnoses considered by the attending physicians were varied Most common was infectious mononucleosis Others were tonsillitis, Hodgkin's disease, mumps, lymphosarcoma, leukæmia, aleukæmic leukæmia, and poliomyelitis

In their nature and variety the signs and symptoms resemble these of infectious mononucleosis Only one thing stands out None of the patients' sera gave a positive Paul-Bunnell reaction This has also been the experience of Siim (1956a)

As with infectious mononucleosis, the incidence is mainly in children and young adults Ten of the patients were under the age of 10, *eleven from 11 to 20, four from* 20 to 30, and five over 30 This predominance in the young is in keeping with the results of serological surveys (Beverley et al 1954) which show that in this country the frequency of toxoplasma antibodies rises to the age of 20 and thereafter changes little

The illness varied enormously in severity and duration Five of the patients (7, 10, 12, 13, and 17) were never

TABLE I—SUMMARY OF THE CASES

of subclinical infection years before Relatives of patients 2, 5, 12, and 20 appear, however, to have been infected about the same time as the patient On retrospective examination glandular enlargement was found in the mother of patient 20 and a brother of patient 12 In the other instances there was no history of recent illness nor were there enlarged glands It is already obvious, from antibody surveys, that sub-clinical infection must be much more common than clinical

Infection in these instances might have been from a common source, might have been from the patient, or might have been from one of his subclinically infected relatives There is as yet no definite evidence of man-to-man transmission Cathie (1954b), however, not only suggested this, but also a possible means of transmission, when he isolated the parasite from the saliva of a child Jacobsson (1953) reported that a father developed a febrile illness a fortnight after the onset of lymphadenopathy in his son Several of Siim's (1951) cases were in members of the same family or in playmates In the present series patient 12 and his 8-year-old brother slept in the same bed Against the theory of human transmission it must, however, be stated that the incidence of positive serological reactions in husbands and wives is no different from what would be determined by the laws of chance

Until more is known it must be assumed that human infection may come from a variety of birds and mammals, including man Toxoplasma has been found in the urine, fæces, and saliva of animals and in the saliva of man Infection might be by direct contamination, by contamination of food, or by consumption of uncooked meat It is very unlikely that consumption of cooked meat could produce infection or even give rise to the production of antibodies, for Rawal (1957) found no difference in the incidence of toxoplasma antibodies in vegetarian Hindus and in meat-eating Christians and Moslems Transmission by an insect vector cannot be ruled out, but many attempts to prove it have failed

TABLE II—ANTIBODY TESTS ON MEMBERS OF PATIENTS' FAMILIES

—	Dye test	Complement-fixation test
Patient 1	1/900	1/40
Father	1/46	<1/5
Mother	1/100	1/5
8 other relatives in close contact—all negative except for one with dye-test titre of 1/46		
Patient 2	1/500	1/5
Father	1/80	<1/5
Mother	1/76	<1/5
Brother, 13 yrs	1/24	<1/5
Sister, 7 yrs	1/880	1/5
Brother, 3 yrs	1/1600	1/10
Brother, 2 yrs	1/5000	1/40
Patient 5	1/1000	1/40
Mother	<1/4	<1/5
Brother, 7 yrs	1/320	1/40
Patient 9	1/340	1/10

Mother	1/80	1/5
2 sisters	<1/8	<1/5
Patient 12	1/820	1/8
Brother 8 yrs (tested 10 months after illness of patient 12)	1/200	1/5
8 other members of household	<1/16	<1/5
Patient 13	1/4800	1/80
Mother	1/160	<1/5
Father and 2 sisters	<1/4	<1/5
Patient 16	1/4000	1/20
Mother	1/8	A C.
Sister	1/5	<1/5
Patient 18	1/50,000	1/20
Father	1/92	<1/5
Mother	<1/4	<1/5
Patient 20	1/900	1/32
Father	1/56	<1/5
Mother (case 29)	1/820	1/16
Brother	1/4	<1/5
Patient 23	1/3200	1/32
Mother	1/40	1/10
Father, 2 brothers, and 1 sister	<1/32	<1/5
Patient 25	1/1000	1/10
Wife	1/15	<1/5
3 children, 1 born while patient was ill	<1/4	<1/5
Patient 26	1/10,200	1/40
Wife	1/47	<1/5
Baby born while patient was ill	1/76	<1/5 (passive transfer)

A C. = anticomplementary

Lymphadenopathy appears to be the commonest manifestation of acquired toxoplasmosis There may be other minor manifestations—perhaps some of the febrile episodes so common in childhood

This is suggested by the finding of high-titre antibodies (dye test 1/1000, complement-fixation test 1/40) in a boy of 2 years (Radcliffe Infirmary no 219832) who developed a few days of fever after a fall He had no glandular enlargement His brother, aged 5, tested nine months later had a dye-test titre of 1/130 and a complement-fixation titre of 1/5 He had not been ill Significant titres were not obtained on serum from the father and mother

Since the commonest manifestation of acquired toxoplasmosis so far recognised is lymphadenopathy which usually begins in the neck, it is tempting to think that infection takes place through the mucous membrane of the tonsillo-pharyngeal region

Summary

Thirty cases of acquired toxoplasmosis resembling glandular fever are reported Four were proved by the isolation of the parasite The others had dye-test antibody titres of from 1/320 to 1/50,000 and complement-fixing titres from >1/5 to 1/80 All had negative Paul-Bunnell reactions

Ten of the patients were under the age of 10, eleven from 11 to 20, four from 20 to 30, and five over 30

Lymphocytosis was found in fifteen and cells of "glandular fever" type were reported in five Sore throat was present in ten

The severity and duration of illness varied enormously Five of the patients were never really ill, whereas in others the illness dragged on for months In such cases fatigue was prominent. None had a high fever and eleven were afebrile

Diagnosis and sources and modes of infection are discussed

We gratefully acknowledge the help given to us by the many physicians and pathologists who supplied us with material from, and information about, the patients We also thank Dr A H T Robb-Smith and Dr R Curran for examining sections and Miss Geraldine Calton, A I M L T, for her skilled technical assistance

Case 21 is published by kind permission of the Director of Medical Services, Royal Air Force

The work was assisted by a grant from the Medical Research Council

references continued overleaf

One patient, not included in this list because, although her dye-test titre was 1/280, her complement-fixation titre was >1/5, had enlarged mesenteric glands 7 months before the enlargement of glands in neck Another had for 2½ years recurrent attacks of pain in the right iliac fossa diagnosed as recurrent mesenteric adenitis or subacute appendicitis A normal appendix was removed but the mesenteric glands were found to be enlarged A month before operation his dye-test titre was 1/540 and his complement-fixation titre 1/80 4 months after operation the results were 1/900 and 1/20 He too has been excluded from the list because confirmation by isolation of the parasite is thought necessary before accepting toxoplasmosis as a cause of mesenteric adenitis unassociated with lymphadenopathy elsewhere

Joseph et al (1957) isolated toxoplasma from an axillary gland of a patient who had mesenteric adenitis, but failed to isolate it from the mesenteric glands of twenty-two others, two of whom had serological reactions indicating recent toxoplasma infection More recently Desmonts (1958) examined the serum of a child who was operated on for appendicitis and found to have mesenteric adenitis The results on a specimen taken 5 days after operation were dye test, 1/100, complement-fixation test, negative 3 weeks later the titres had risen to dye test, 1/2500, complement-fixation test 1/100

Reid and Manning (1956) noted symptoms attributable to mesenteric adenitis in three of their thirteen patients, and in both of Pinkerton and Henderson's (1941) fatal cases of typhus-like toxoplasmosis the mesenteric glands were enlarged Makstenieks and Verlinde (1957) isolated toxoplasms from the mesenteric glands of inoculated monkeys

Fatigue was common and in some cases long-continued Possibly this may be due to infection of the musculature, for toxoplasms have been demonstrated in, or isolated from, muscle tissue (Kass et al 1952, Couvreur 1955, Siim 1956b, Kayhoe et al 1957)

The blood-picture showed an absolute leucocytosis in six patients, while five others, adults, had leucocyte-counts of between 9000 and 10,000 per c mm Lymphocytosis (under 5 years, >6000, over 5 years >3000) was found in fifteen patients In most it was slight and the highest figure recorded was 11,500 per c mm Cells of "glandular fever" type were reported in six patients (4, 14, 19, 22, 27, and 28) while atypical cells not typical of glandular fever were reported in patient 21 A high eosinophilia, 3150 per c mm, was found in only one patient (2) Patients 1, 5, 6, and 25 had eosinophil-counts of from 400 to 700 Of these patients no 1 suffered from asthma and infantile eczema From only one of the patients (19) was bone-marrow taken for examination The hæmatological report on this was that it was normal apart from apparent "glandular fever" cells, but of considerable interest was the discovery of bodies morphologically resembling toxoplasma Unfortunately no bone-marrow was left for mouse inoculation and, as the patient had experienced considerable pain, it was not thought justifiable to repeat the marrow puncture This is to be reported in greater detail elsewhere

In none of the patients was a rash reported, but patient 25, 2 days after he took ill, had a red elevated irregular area on the skin of the outer surface of his left leg In two other probable cases (not included) a rash was found

One was of a boy aged 12 who, besides glandular enlargement, had a discrete, papular, erythematous rash, at first over the body and later confined to the trunk His dye-test titre was 1/190 and his complement-fixation titre 1/16 The other was of a man aged 21 who had a sparse macular rash on the trunk His axillary, inguinal, and posterior cervical glands were enlarged, he had a lymphocytosis, and atypical mononuclear cells were found in his blood His dye-test titre was 1/160 and his complement-fixation titre 1/10 The Paul-Bunnell reaction was negative in both cases

Only one of the patients (25) had pulmonary symptoms They were slight cough and sharp pain in the left lower chest, accentuated by deep breathing In another (8) enlarged hilar glands were found on X-ray examination

No serious sequelæ were observed in the present series, but Wising (1952) and Kayhoe et al (1957) reported choroidoretinitis, and one of Strom's (1951) patients developed myocarditis, meningeal irritation, and encephalitis The second patient of Kayhoe et al had increased protein and cells in the cerebrospinal fluid There is also a possibility, suggested by Finckh (1954) and by Siim (1956a), that malignant changes may take place in the glands

A particular danger is the development of toxoplasmosis during pregnancy, because the infection may be passed to the fœtus As a rule the mother's infection passes unnoticed, but Couvreur (1955) on careful inquiry found evidence of illness in seventeen of twenty mothers In seven it was asthenia and in six lymphadenopathy Farquhar (1950) also noted lymphadenopathy in a woman who gave birth to a child with congenital toxoplasmosis, and Alexander and Callister (1955) and Siim (1956b) have found toxoplasms in both mother and child

The remedy found most effective, so far, in trials on animals is a combination of sulphadimidine and pyrimethamine (Eyles 1956, Beverley and Fry 1957) Jacobs et al (1956) and Perkins et al (1956) found this of some value in toxoplasmic uveitis, and Wettingfield et al (1956) and Kayhoe et al (1957) in toxoplasmosis with glandular enlargement Only one patient in this series (19) was treated with this combination During treatment her temperature fell but her illness persisted

An important question, to which there is as yet no satisfactory answer, concerns the source of human toxoplasmosis Animals have often been suspected and toxoplasmosis has been found in patients closely associated with infected dogs, cats, and rabbits In the present series patient 21 had much contact with 7 guard dogs, 3 of which had dye-test titres of over 1/160 No illness, however, had been noted in the dogs nor did their handlers have high titres Patient 23 was a veterinary student and exposed to particular risk because he had examined toxoplasma-infected dogs post mortem Patient 25 was a carter and had previously kept greyhounds No toxoplasma antibodies were found in the blood of his horse nor in others that he handled Twelve of the patients had contact, in some cases close, with cats

Cats associated with patient 1 had dye-test titres of 1/400 and 1/70, with patient 3 of 1/70, 1/9, 1/5, 1/25, and 1/160, with patient 17 of 1/128, and with patient 23 of 1/85 and 1/95 Toxoplasms were isolated from brain of the cat with a dye-test titre of 1/160 It was not attempted in the cats with dye-test titres of less than 1/50 and failed in the others Jones et al (1957) isolated toxoplasms from 50% of cats with titres of 1/64 or higher

Five of the patients had contact with budgerigars

Patient 14 had as her personal pet a bird which had been sick with vomiting on several occasions from May to September The husband of patient 27 bred budgerigars The birds in contact with patients 1 and 3 did not, however, have detectable antibodies to toxoplasma

In several instances members of a patient's family were also examined for antibodies This yielded interesting results, which are shown in table II In the case of patients 1, 9, 13, 16, 19, 23, 25, and 26 the relatives had either no antibodies or low-titre antibodies believed to be the legacy

TABLE II—EFFECT OF THYROXINE ON MEAN REACTION TIMES OF MYXŒDEMATOUS PATIENTS

Age	Mean reaction time (sec)			
	No of persons	Before therapy	After therapy	Normal mean
<40	4	0 303	0 2287	0 2286
40–50	7	0 322	0 2374	0 2396
50–60	7	0 317	0 2466	0 2546
>60	6	0 423	0 2570	0 2598

These normal ranges are also shown in table I There was no statistically significant difference between repeated readings in healthy people on different dates The reaction times of the 10 severely anæmic patients all fell within these normal ranges The mean values for the reaction times of the 50 hypothyroid patients for each age-group are also shown in table I There is a significant difference between each and the corresponding normal mean It can be seen from fig 2 that the reaction times of 46 of these patients lay outside the normal ranges The reaction times of the 9 myxœdematous patients who had been euthyroid for a considerable period were all within the normal ranges for their ages During therapy the reaction times of the myxœdematous patients decreased, and it can be seen (fig 3) that, when 23 of the 25 patients had become euthyroid, their reaction times lay within the normal ranges This happened both in the patients observed at intervals and in those in whom the test was repeated only when they were euthyroid These changes are statistically significant One patient, while hypothyroid, had a reaction time just within the normal range, but after treatment her "normal" reaction time was faster than normal for her age In a cretin, aged 14, who had neglected to continue her treatment there was also an improvement on further therapy, but, when she was euthyroid, her reaction time was still much prolonged This improvement corresponded to a clinical impression of increased alertness, although she still remained mentally retarded Table II shows the mean reaction times (excluding this case) before and after therapy For each age-group the values when the patients had become euthyroid, approached the mean for healthy people The improvement in the reaction times in the hypothyroid patients after treatment paralleled the changes in B M R

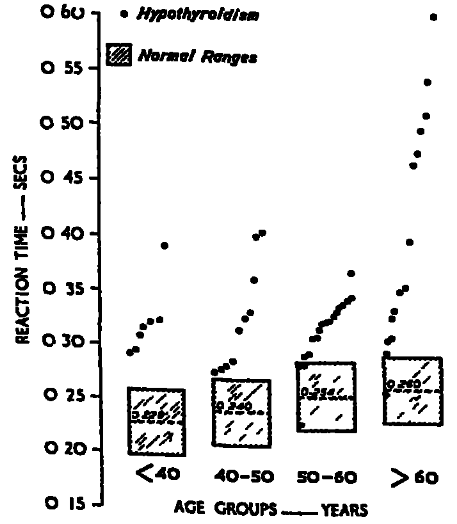

Fig 2—Reaction times of 50 hypothyroid patients showing the prolongation outside normal ranges (hatched areas)

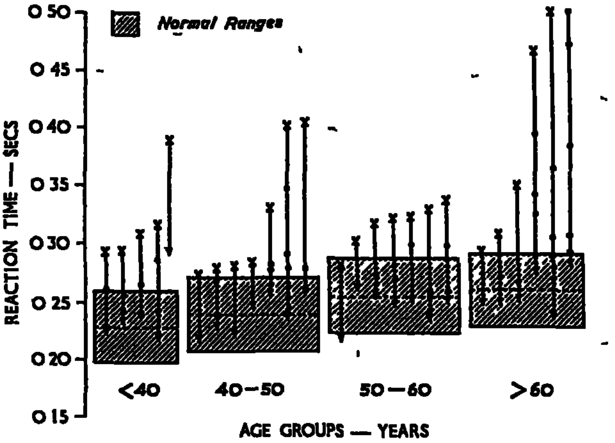

Fig 3—Effect of therapy on reaction times of 25 hypothyroid patients x, initial reading, ●, readings during period of control, v, final reaction time when patient was euthyroid

and serum-cholesterol levels This pattern is illustrated by fig 4, which shows the response to triiodothyronine in a myxœdematous female aged 44 The reaction time improved rapidly and within four days was within the normal range, where it has remained for a year

In both the healthy people and the myxœdematous patients dexamphetamine sulphate decreased the reaction time However, as can be seen in fig 5, this decrease was greater and more prolonged in the myxœdematous patients than in the healthy people The mean maximal quickening for the patients was 0 0524 seconds, compared with 0 0248 seconds for healthy people

Discussion

The method of measuring reaction time used in this study has many advantages over other methods In particular the apparatus is portable and inexpensive and allows considerable accuracy in timing The rapidity with which observations may be repeated also permits allowance

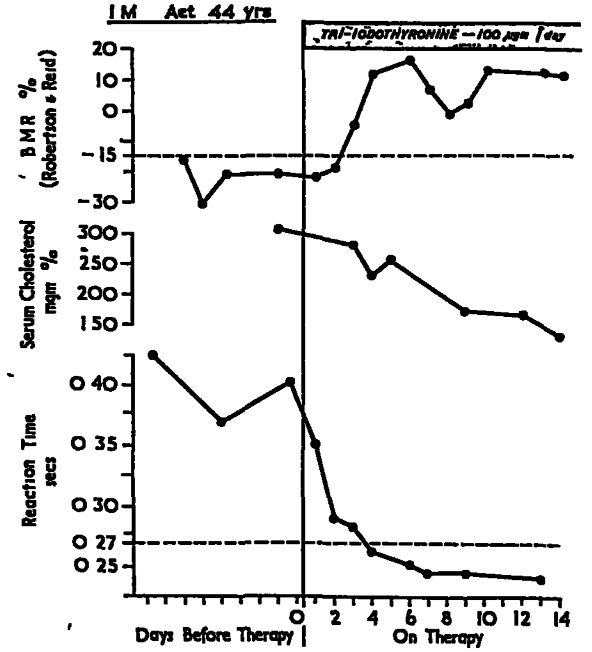

Fig 4—Effect of triiodothyronine on B M R., serum-cholesterol level, and reaction time in a myxœdematous patient

THE REACTION TIME IN MYXŒDEMA

I P C Murray
M B Glasg , M R C P E
HALL TUTORIAL FELLOW, UNIVERSITY DEPARTMENT OF MEDICINE, GARDINER INSTITUTE, WESTERN INFIRMARY, GLASGOW

The reaction time, which measures the interval between the application of a stimulus to a sensory organ and a voluntary response, is known to be influenced by various factors Increasing age and fatigue, for example, lengthen it, as do depressant drugs such as alcohol and the barbiturates It seemed possible that the reaction time would also be prolonged in myxœdema, and that it might be correlated with the degree of thyroid underactivity A simple and rapid method of measuring the reaction time to a visual stimulus was therefore devised and has been used in healthy people, anæmic patients, and patients with myxœdema The effects of specific therapy and of dexamphetamine sulphate on the reaction time have also been studied

Method

The circuit of the apparatus used to measure reaction time is shown in fig 1 After the subject has depressed key 2, the observer depresses key 1, thus closing the relay contacts AB and CD As a result the red lamp lights, and the scaling unit is operated by the relay contacts AB and key 2 acting via the electronic gate The scaling unit records pulses at twice the mains frequency (100 c p s) until key 2 is released by the subject, when the scaler stops (again using the electronic gate) and records the reaction time in seconds up to 9 99 secs

The subject is instructed to depress the button (key 2) and, immediately he sees the red light, to remove his finger from the button as rapidly as possible The operator continues to keep his key depressed until after the scaler has stopped and then resets the scaler Several practice tests were made with each subject to ensure that the instructions were understood Reaction times were measured at irregular intervals of 5–10 seconds to avoid anticipation Long intervals were avoided to prevent the subject's attention from wandering In 5 healthy people and 4 myxœdematous patients a minimum of two hundred consecutive readings were taken After the first ten to fifteen tests had been made, there was little difference between the mean of each succeeding group of ten Accordingly, for each person fifty readings were taken, the first twenty being discarded, and the mean of the last thirty recorded as the reaction time A visual stimulus was used rather than aural because myxœdematous patients often have impaired hearing

TABLE I—MEAN REACTION TIMES

Age (yr)	Healthy			Hypothyroid	
	No of persons	Mean (sec)	Normal range M ± 2S	No of persons	Mean
<40	34	0 2286	0 1974–0 2598	7	0 3200
40–50	21	0 2396	0 2084–0 2708	10	0 3053
50–60	26	0 2546	0 2234–0 2858	18	0 3141
>60	20	0 2598	0 2286–0 2910	15	0 4313
Total	101			50	

Control subjects —This group consisted of 101 healthy people aged 17–83 years and included medical staff, laboratory personnel, and patients in whom there was no evidence of thyroid dysfunction A further 10 persons with normal thyroid function but with anæmia from various causes (hæmoglobin less than 60%) were also studied In 5 healthy people the test was repeated at intervals of several weeks

Hypothyroid patients —50 patients were studied The condition was idiopathic in most cases but in some it was secondary to hypopituitarism, Hashimoto's thyroiditis, thyroidectomy, or radio-iodine therapy Radio-iodine studies and estimations of basal metabolic rate (B M R) and of serum-cholesterol level were made in most subjects If the diagnosis was uncertain on clinical grounds, a final diagnosis was made only after the results of the administration of *l*-thyroxine sodium were known 20 of the patients were reviewed at intervals during therapy, and repeated estimations of B M R , serum-cholesterol level, and reaction time were made In 5 patients the reaction times were determined only before and after return to the euthyroid state to eliminate the possible effects of practice Reaction times were also estimated in a further 9 patients with proved myxœdema who had been euthyroid on thyroxine therapy for periods of six months to two years In all cases it was ascertained that no barbiturate was being administered

Dexamphetamine sulphate —This drug was administered orally in a dosage of 15 mg to 6 healthy people and 7 myxœdematous patients, and the reaction time was recorded at intervals for the following four to four and a half hours

Results

The mean reaction times of the healthy people for the four age-groups analysed are shown in table I The pooled standard deviation is ±0 0156 seconds If M is the mean of a group and S the pooled standard deviation, then, if the members are normally distributed, the range M±2S is one in which 95% of the normal reaction times will lie

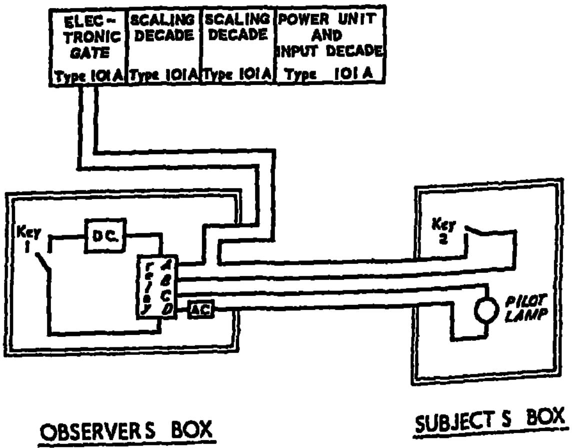

Fig 1—Circuit diagram for apparatus used to measure reaction time

MOVEMENTS OF THE COMMON BILEDUCT IN MAN

STUDIES WITH THE IMAGE INTENSIFIER

W Burnett
M B Aberd, F R.C S
HONORARY LECTURER IN SURGERY

R Shields
M.B Glasg
HALL FELLOW IN SURGERY

UNIVERSITY OF GLASGOW

For many years the method by which bile enters the duodenum has been of great interest to the physiologist and the clinician Most studies, however, have been concerned with the mechanism of emptying of the gallbladder and its functional relationship with the sphincter at the distal end of the common bileduct Little attention has been paid to any active part which might be played by the common bileduct, which is usually considered to be a transmitting tube with a wall mainly composed of fibrous tissue.

In 1889, soon after Oddi's pioneer work, Copeman reported studies on a patient with a complete external biliary fistula associated with a stone which had completely occluded the common bileduct at its distal end He noted that the secretion of bile was not continuous, but that there were "short periods of rest, followed by a flow in a series of jerks, which appeared to be caused by waves of peristaltic contraction" This hint of peristalsis in the common bileduct was followed by Mirizzi (1940), who described possible peristaltic movements in the duct and demonstrated contraction of a sphincter at the distal end of the common hepatic duct. These observations were made from a study of operative cholangiograms This work has not been confirmed

It occurred to us that it might be possible to study the common bileduct under more physiological conditions in the unanæsthetised patient by using image intensification, which would permit fluoroscopic screening with the additional possibility of recording the findings by cineradiography We have so far been unable to make any satisfactory observations by using intravenous cholangiography, owing to difficulty in obtaining definition of the biliary tract of sufficient intensity for satisfactory screening However, studies have been made after surgical exploration by the direct injection of a radio-opaque contrast medium into the common bileduct. We describe here the peristaltic movements which we have seen in the common bileduct in 10 patients after cholecystectomy

Methods and Results

The biliary tree was examined radiologically with an image intensifier one or two weeks after cholecystectomy or choledochotomy A water-miscible contrast medium, 50% or 70% sodium acetrizoate, was instilled at the rate of 1 ml a minute into the common bileduct The injection was made through a ureteric catheter which had been inserted at operation for a distance of about 1 cm. into the common bileduct through the stump of the cystic duct. If the common bileduct had been explored, the injection was made through a short T-tube left in the common bileduct at operation An initial injection of 3 ml was made. Screening was done at this time to observe the filling of the duct As the duct emptied into the duodenum, further increments of the same or less volume were instilled, the amount being determined by the rate of emptying No disturbance was experienced by the patient, and no distension of the common bileduct was allowed to take place at any time. Observations were made both during the injection and afterwards After 5–10 minutes for stabilisation of conditions in the duct permanent records were made on 35-mm film by cineradiography with a built-in 'Arriflex' camera so arranged that screening and cineradiography could be done simultaneously It was found suitable to take the film at a rate of 16 frames a second

Ten patients were studied, similar findings being made in each case

Movements of Common Bileduct and Duodenum

Four different types of movement were observed in the bileduct and the related portion of the duodenum Details of these movements were more obvious in thinner patients because visualisation was easier

Peristalsis of Common Bileduct

We observed waves of peristalsis in the common bileduct in all ten patients studied, whether or not the common bileduct was intact or had been previously explored The peristaltic waves travelled towards the duodenum at the rate of 3–5 or more a minute and lasted 1–3 seconds On one occasion 5 waves were seen in 36 seconds Sometimes a minute or more elapsed without a contraction Not all of the waves were complete and brought the medium into the duodenum, some were abortive, ending near the sphincter, but, when a wave travelled the whole length of the duct, the medium was ejected forcibly into the duodenum, and a successful complete wave was usually followed by several more At the end of a phase of peristalsis a well-marked retraction was seen at the lower end of the duct, which changed from a slender tapering channel to a shorter wider one with what appeared to be a blunt and almost rectangular tip This appearance is similar to that produced by an injection of morphine. These peristaltic movements are seen in ducts which are not under increased pressure and are not being injected with contrast medium at the time of observation

The supraduodenal angle of the duct is a suitable point for orientation when screening This point is situated just distal to the junction of the cystic and common bileducts Distal to the angle the common bileduct changes direction to run downwards and slightly laterally to its termination When contrast medium first enters the common duct through the cystic-duct stump it runs distally towards the duodenum Some minutes later it fills the common hepatic and the right and left hepatic ducts This initial distal movement may be of no significance and result from flow along a distally directed catheter On the other hand, it may support the suggestion made by Mirizzi (1940) that a sphincter is present at the to be made for the effects of practice, which Forbes (1945) and others have demonstrated

Mental sluggishness, lethargy, impaired memory, and lack of concentration are common complaints of patients with frank myxœdema, and even mild cases of hypothyroidism may be present with symptoms of this type Since the reaction time reflects higher mental processes (Evans 1947), it is not surprising to find it lengthened in myxœdema In a few patients with gross mental apathy resulting from hypothyroidism the test was made more difficult as a result of their inability to understand the instructions In many of the other cases the diagnosis of hypothyroidism could only be made after full investigation, including the response to a therapeutic trial In such patients the mental and physical slowing is much less, and it is often this which gives rise to diagnostic difficulty However, in 46 of these 50 patients the reaction times were prolonged The possibility that the anæmia which may be associated with myxœdema might play a part in the prolongation of the reaction time was eliminated by the finding of normal reaction times in severely anæmic patients

The 4 myxœdematous patients who had reaction times within the normal ranges are of special interest One was an electric welder, a skilled occupation which involved quick and rapid movements of the hands, and he had noted that he was not producing such good work as formerly The reaction time of another of these patients lay just within the upper limit of the normal range, but, when she became euthyroid, her " normal " reaction time lay below the lower limit of the normal range, suggesting that there had originally been a considerable prolongation The 2 other patients had only recently become hypothyroid as a result of radio-iodine therapy It seems possible, from these and other patients studied subsequently, that the hypothyroid state must be present for some time before the reaction time increases

When the diagnosis of hypothyroidism is obvious on clinical grounds, there is no need for further investigation, confirmation being obtained by the response to specific therapy For the investigation of cases in which the clinical picture is atypical or incomplete numerous tests have been described, but only a few have been generally adopted In such difficult cases, however, the results even of these investigations may be of doubtful significance—e g, radio-iodine studies on patients partially treated Similarly, electrocardiograms and estimations of serum cholesterol levels and B M R are often helpful but may at times give equivocal results I therefore suggest that, in cases of suspected myxœdema, the measurement of reaction time is a simple and rapid aid to diagnosis which causes minimal inconvenience to the patient Moreover, a useful index of the response of the patient to therapy is provided by the improvement in reaction time In general this parallels the changes in the clinical picture, the B M R, and the cholesterol level (fig 4) One patient stopped therapy on her own initiative, and her reaction time, which had remained within the normal range for five months when she was euthyroid, again became prolonged

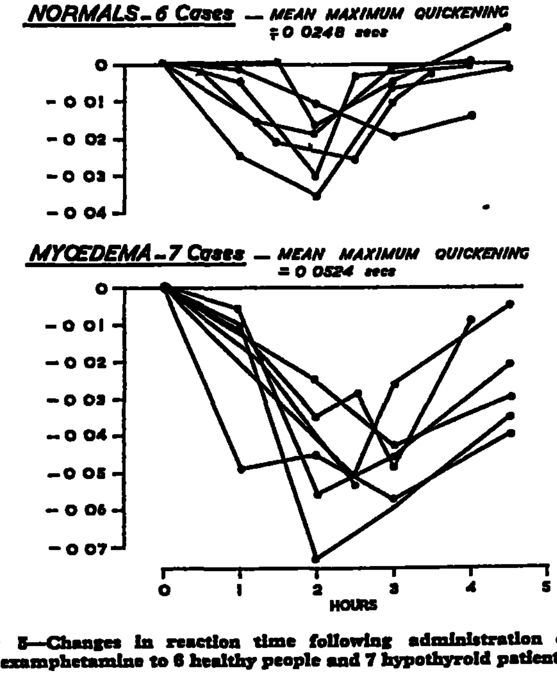

Fig 5—Changes in reaction time following administration of dexamphetamine to 6 healthy people and 7 hypothyroid patients

The changes in reaction time in myxœdema probably reflect the changes in cerebral function The results are comparable with those of Gantt and Fleischmann (1948), who studied the conditioned-reflex function in a cretin and showed that, after successful therapy, there was an improvement which reached a level in two months but did not change further over two years Other workers have studied the changes in cerebral function in myxœdema, using recognised psychological techniques, and have found evidence of impairment—e g, Reitan (1953), who used the Rorschach test Further evidence that the effect is on the higher centres is provided by the results of the studies of the effect of dexamphetamine sulphate (fig 5) After the administration of this cerebral stimulant there was a definite quickening of reaction time in healthy people When it was given to myxœdematous patients, the quickening was much greater and lasted considerably longer The possibility arises that the impairment of reaction time might be influenced by delay in the peripheral component of the arc, but this is unlikely in view of the findings of Murray and Simpson (1958), who showed that the conduction velocity in peripheral nerves was not appreciably altered in hypothyroidism Similarly, Lambert et al (1951) concluded that, although the total time taken for the ankle-jerk in myxœdema was increased, there was no appreciable difference in the speed of conduction through the reflex arc in healthy people and in myxœdematous patients They emphasised that this reflex took place over a two-neurone arc which does not involve the more complex activity of the central nervous system, as does the reaction-time pathway The estimation of reaction time therefore provides a quantitative index of one aspect of mental activity which is not only more accurate than many conventional tests but also is more easily applied and more readily adaptable to routine clinical use

Summary

By a simple and rapid method reaction times were estimated in 101 healthy people, 50 patients with hypothyroidism, and 10 patients with severe anæmia

In 46 of the hypothyroid patients, the reaction time was prolonged Specific therapy in 25 of these led to quickening of the reaction time, which returned to normal in 24, paralleling the changes in B M R and serum-cholesterol levels

Dexamphetamine shortens the reaction time of hypothyroid patients to a greater extent than that of healthy

observed peristaltic and respiratory movements of the common bileduct was possible after some of the contrast medium had entered the duodenum from the duct As has been described above, the duodenum and the common bileduct move together during respiration In addition, forward and reverse peristalsis is clearly seen in the duodenum itself We have not found that this peristalsis plays an active part in emptying the duct No duodenal movement is usually seen while the duct is expelling its contents in jets through the duodenal papilla, nor does any active duodenal contraction precede this But duodenal peristalsis usually begins after one or more waves of bileduct contraction This peristalsis is initially in the reverse direction, so the contrast medium is swept upwards towards the first part of the duodenum and the pylorus This movement is followed by forward peristalsis This succession of duodenal contractions would be expected to lead to efficient mixing of food, bile, and pancreatic juice in the second part of the duodenum

Previous observations on the functional relationship of the intraduodenal portion of the common bileduct to movements of the duodenum were made by Lueth (1931) and Long (1942) Both made their experimental studies on dogs, and both thought that the sphincteric region and the duodenal wall usually acted together Lueth thought that the intraduodenal portion was capable of independent action Our own finding that the duct empties into the duodenum while the duodenum is relaxed confirms a similar finding by Lueth It also supports the concept of an integrated functional relationship between the common bileduct and the duodenum, in that a true peristalsis (by the definition of Bayliss and Starling) in the common bileduct is preceded by a relaxation in the duodenum before the peristaltic wave reaches it

Histological Structure of Common Bileduct

It is commonly believed that the common bileduct in man is a fibrous structure containing no muscle except at its termination Standard textbooks of anatomy do not agree on its histological structure Brash and Jamieson (1937) briefly describe it as agreeing with the gallbladder in structure Johnston and Whillis (1954) say that the fibrous coat of the duct is "composed of strong fibro-areolar tissue, with a certain amount of muscular tissue, arranged, for the most part, in a circular manner" On the other hand, Grant (1940) feels that "the extrahepatic ducts are fibrous tubes containing many elastic fibres but without a muscle coat" This opinion is also held by Kozoll et al (1957), who describe the wall of the duct as consisting of "a meshwork of interlacing collagen and elastic fibres . smooth muscle is only seen in the intra-duodenal segment"

Burden (1925) reported on the structure of the supraduodenal portion of the common bileduct, basing his description on a study of 100 necropsy specimens He found that the bileducts were supplied with a well-developed musculature The muscle was situated in the outermost layers of the wall, both in longitudinal and circular bundles, the former being the more notable Burden could not find a published description of peristalsis in the human bileduct but thought it possible from its structure

Our observations on the supraduodenal bileduct in man show that there is indeed an interlacing network of collagen and elastic fibres in the wall as described by Grant (1940) and Kozoll et al (1957), but there is smooth-muscle tissue in the duct (fig 3) varying in amount with the individual, the muscle-fibres interdigitating with collagenous and elastic tissue

Discussion

We have shown that peristaltic movements occur in the common bileduct in man, and we are convinced that the anatomical basis for this is present

Following these observations, we have begun a comparative study of histological structure and biliary-tract movements in animals We have confirmed that obvious peristalsis can be seen under anæsthesia where there is muscular tissue in the duct wall The occurrence of peristalsis is not related to the presence or absence of a gallbladder in the species concerned (unpublished observations)

Peristalsis has not been described in the common bileduct at operation, but this need not imply that it does not occur under physiological conditions At operation the effect of the drugs used for premedication and for anæsthesia may be sufficient to reduce or to abolish movements, the length of bileduct actually exposed and available for study is usually short, and it is rare for a healthy duct to be closely examined We have studied movements of the duct only after cholecystectomy, perhaps they occur as a compensatory mechanism after cholecystectomy However, the gallbladders removed before the radiological studies in this series had obviously been functionless for many months

As a result of this study we believe that the common bileduct functions as an actively contracting duct rather than as a passive transmitter of bile This concept may modify current views on the genesis of biliary pain and permit the consideration of common bileduct colic as

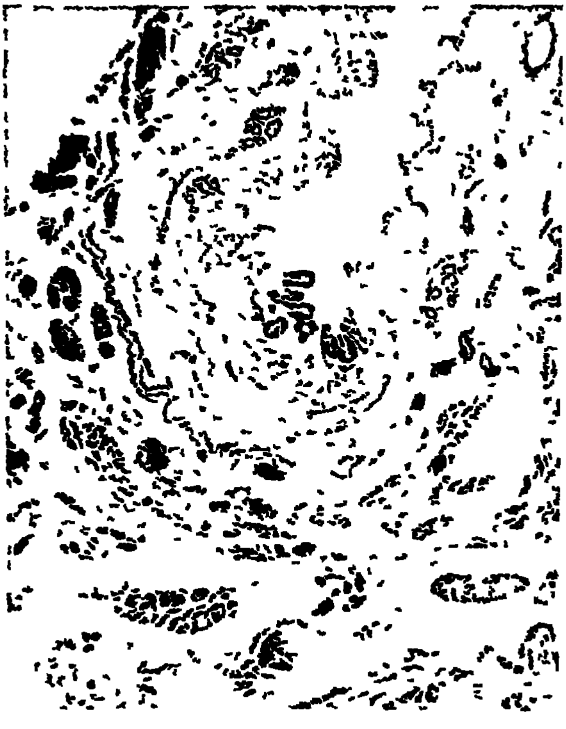

Fig 3—Cross-section of distal quarter of human common bileduct proximal to intraduodenal portion Smooth muscle is present, chiefly in outer coat Muscle bundles are mainly longitudinal but there are some oblique and circular fibres Mucosa has been almost completely destroyed by autolysis (Hæmatoxylin and eosin. ×40)

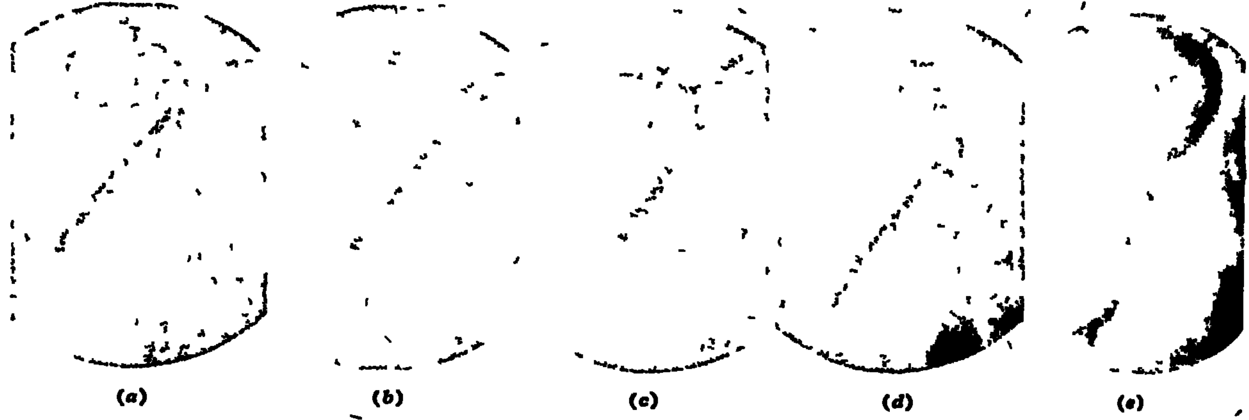

Fig 1—Stages in peristaltic waves in distal common bileduct, from cineradiographic film of biliary tract of woman, aged 38, who underwent cholecystectomy 10 days earlier Times between photographs a–b, 4 9 sec , b–c, 2 3 sec , c–d, 2 9 sec , d–e, 8 0 sec

distal end of the common hepatic duct Mirizzi's argument is supported by cholangiograms made during operation, which show extreme narrowing of the main bileduct at the junction with the cystic duct These may possibly represent movements of maximal contraction during a peristaltic wave, but in this region of the duct the peristaltic waves which we have seen do not cause complete obliteration of the duct They can be described as ripples progressing distally, which can be clearly identified but do not completely occlude the duct Distal to the supraduodenal angle the contractions are greater, making greater indentations in the duct wall as the peristaltic wave passes along

These peristaltic waves can be seen easily on screening and have been reproduced by cineradiography It has not proved possible to illustrate them completely by serial reproductions from a film strip, but some aspects can be seen in figs 1 and 2 taken from a cineradiographic film of the bileduct of a female patient, aged 38, who underwent cholecystectomy for gallstones 10 days earlier At operation the common bileduct appeared normal, and this was confirmed by operative cholangiography The duct was not explored In figs 1 and 2 a ureteric catheter can be seen entering the common bileduct through the stump of the cystic duct Through this catheter 70% sodium acetrizoate was injected into the common duct

Fig 1 shows various stages in peristaltic waves which have reached the distal common bileduct The medium can be seen entering the empty duodenum Comparison of fig 1a and fig 1d, with reference to the relation of the supraduodenal angle of the duct to the vertebræ, shows the extent of normal respiratory movement

Fig 2 shows the considerable change in the appearance of the same duct 20 minutes later Various stages in waves in the distal portion of the duct are reproduced for comparison with fig 1 In addition fig 2d shows the appearance of the duct in its resting or nonperistaltic state at the completion of a wave 5 7 seconds after the exposure of fig 2a The appearance of the duct in fig 2d is very like that seen after a subcutaneous injection of morphine

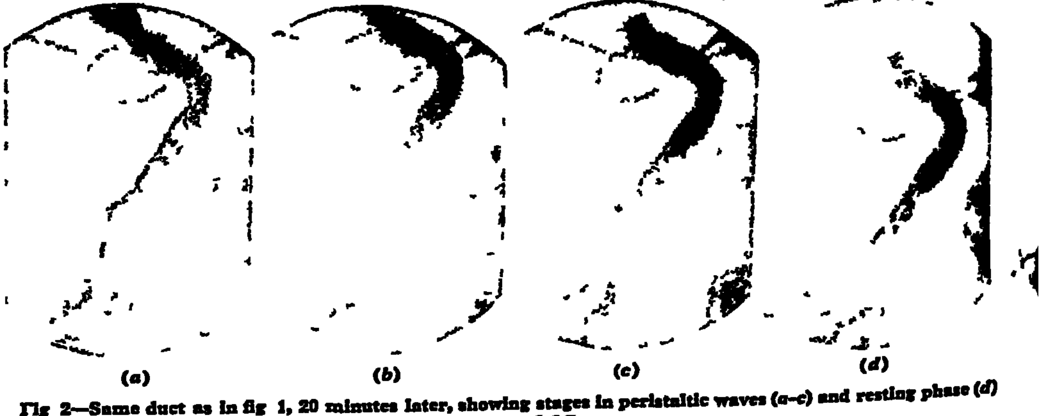

Fig 2—Same duct as in fig 1, 20 minutes later, showing stages in peristaltic waves (a–c) and resting phase (d) Times between photographs a–b, 2 1 sec , b–c, 1 sec.; c–d, 2 7 sec.

Respiratory Movement

The whole biliary tree moves with each respiratory excursion, a downward movement in inspiration is followed by a return upward movement in expiration The bileduct and the duodenum move together, but the ejection of contrast medium into the duodenum is not in any way associated with these movements In common with many other workers we have observed, by simple manometry, that pressure changes occur in the common bileduct during each respiratory cycle—normally about 1 or 2 cm of bile These minor but definite rises in pressure can be considerably increased by deep inspiration or by coughing, but they do not appear to contribute to the emptying of the common bileduct, because the emptying of the duct into the duodenum is not regularly related to the observed respiratory movement or significantly increased by deep inspiration or by coughing

Transmitted Arterial Pulsation

In a patient with a thin abdominal wall it is possible to see, on screening, that the common bileduct pulsates synchronously with the aorta This is not surprising, because the aorta and the cœliac axis are close to the duct, and the hepatic artery runs in intimate relationship with the duct, hence transmitted pulsation may be expected This movement is of minor degree and has no bearing on the emptying of the duct

Associated Duodenal Movements

A study of duodenal movements in relation to the

Results

All the patients with steatorrhœa had impaired diuresis compared with the controls both when the water loads were given orally (fasting or non-fasting) or when they were given intravenously in the fasting state. Cases 1–5 and 8 achieved diuretic responses within the normal range but not under all three test conditions. In patients with steatorrhœa there was a wider range of response under all the test conditions than in the controls. The mean excretion of fluid after each method of giving the water load was between 48–58% in the patients with steatorrhœa and 100–114% in the controls (fig. 1). Fasting did not influence the diuretic responses to oral water loads in the patients with steatorrhœa.

The diuresis was subnormal not only in the patients with idiopathic steatorrhœa but also in those with malabsorption due to total or partial gastrectomy, Crohn's disease, tuberculous enteritis, or jejunal diverticulosis (see table). There was a correlation between the impairment of diuresis and the severity of the disease, the mean excretions in the three test conditions being grossly impaired in grade-III patients and relatively intact in grade-I patients (fig. 2). In case 11 diuresis improved three weeks after treatment, in keeping with the clinical improvement (see table).

The hæmoglobin level was 12 g. per 100 ml. or below in 5 patients, the anæmia being macrocytic in 3, normocytic in 1, and due to iron-deficiency in 1. The anæmia was severest in grade-III patients, thus being associated with defective diuresis. There was no relationship between the degree of steatorrhœa and the diuresis (fig. 3).

Clinical and radiological evidence of intestinal distension was present in cases 4, 6, 7, 13, and 14. "Steatorrhœa" patterns were found in cases 2–4, 6, 8, and 10–14. There was therefore no relationship between impaired diuresis (see table) and the degree of distension of the small intestine or other radiological appearances.

Serum-potassium levels were low in some patients,

an entity similar in nature to ureteric and intestinal colic

Summary and Conclusions

By image intensification and cineradiography we demonstrated peristaltic movements in the common bileduct in man after cholecystectomy

The waves of peristalsis were directed distally along the duct towards the duodenum and propelled bile into the duodenum

Respiratory and duodenal movements were also studied, they played no great part in emptying the bileduct under the conditions of our observations

We believe that there is sufficient muscle in the wall of the bileduct to produce these observed rhythmic movements, and conclude that this intrinsic muscle is responsible

We thank Professor Illingworth and Dr Scott Park for providing facilities to make this study, and the radiographers of the Western Infirmary, Glasgow, for their cooperation

Disordered metabolism of water in idiopathic steatorrhœa is suggested by the tendency to œdema of the ankles and nocturnal polyuria Wollaeger and Scribner (1951) showed that, after an oral water load in such patients, diuresis was impaired in the non-fasting state but not when the patients were fasting They therefore concluded that the presence of food, with pooling of fluid in the intestines, delayed the absorption of water and consequently retarded its excretion Taylor (1955a), however, could not improve the defective diuresis by fasting in idiopathic steatorrhœa

We report here diuretic responses to water loads in various malabsorption states, including idiopathic steatorrhœa In particular we compare the effects of intravenous and oral loads given to fasting and non-fasting persons

Materials and Methods

We studied 14 patients with malabsorption syndromes (see table) 3 had idiopathic steatorrhœa, 4 regional ileitis (including 2 with resections of small intestine), 1 tuberculous enteritis followed by resection of terminal ileum, 1 jejunal diverticulosis, and 5 steatorrhœa following total or partial gastrectomy The fæcal fat averaged more than 5 g per twenty-four hours over three days on varied ward diets, thus conforming with Cooke's (1956) criteria for steatorrhœa Additional diagnostic investigations, by standard methods, included examination of peripheral blood and sternal marrow, estimations of serum-protein and serum-electrolyte levels, radiological studies of the alimentary tract and bones, surgical or aspiration biopsies of the small intestine, and oral glucose-tolerance tests

The patients were divided into three clinical grades of severity judged particularly by loss of weight and by disability grade I, mild or in remission, grade II, moderately active disease, grade III, severe relapse requiring admission to hospital (see table)

In no patient did the history, clinical findings, specific gravity and routine analysis of the urine, or blood-urea level suggest renal disease

We studied as controls 19 persons, of comparable age and sex, recruited from hospital staff and patients None had evidence of renal, hepatic, cardiac, endocrine, or gastrointestinal disease with the exception of peptic ulcer

The subjects received oral tap-water loads (20 ml per kg of body-weight) under fasting and non-fasting conditions and intravenous water loads as 5% dextrose (15 ml per kg of body-weight) in the fasting state For fasting tests nothing was allowed by mouth after 10 P M the previous night After the bladder had been emptied next morning, the fluid was given within forty-five minutes, and the output of urine over the next four hours was measured Non-fasting tests were made after the midday meal but otherwise with the same routine The patients were recumbent during the tests, and the volume of urine was recorded as a percentage of the intake of fluid under each of the test conditions The mean percentage of the fluid loads excreted was calculated from the volume of urine excreted in four hours after the three tests

HÆMORRHAGIC PLEURAL EFFUSION AS A MANIFESTATION OF SCURVY

WILLIAM ROZNER
M D Strasbourg, D T M & H
CHEST PHYSICIAN, NEWCASTLE REGIONAL HOSPITAL BOARD

JUNE LLOYD
M B Bristol, M R C P
JUNIOR HOSPITAL MEDICAL OFFICER, SOUTH SHIELDS HOSPITALS

SCURVY in Great Britain is not as rare as previously believed (Thompson 1954, Cutforth 1958) The clinical manifestations now encountered differ greatly from the textbook descriptions

Case-report

A joiner's labourer, aged 62, was seen by one of us (W R) on April 24, 1957, at his home with six weeks' history of right pleural pain and increasing dyspnœa He was admitted the same day to Primrose Hill Hospital, Jarrow on Tyne

In October, 1954, he had had epigastric pain between meals, relieved by alkalis and vomiting A barium meal examination that year showed a large gastric ulcer on the lesser curve extending into the posterior wall The chest radiograph was then normal

First previous admission—In January, 1955, he had been admitted to another hospital for treatment of his peptic ulcer His hæmoglobin (Hb) was 101%, leucocyte-count 8800 per c mm (normal differential count), urine normal, Wassermann reaction and Kahn test negative, fæcal occult blood present in one of six specimens He was treated with diet, alkalis, and iron, and discharged improved at the end of five weeks to continue with the same treatment and to attend for review as an outpatient On March 3, 1955, barium meal did not show the previously noted ulcer crater The chest radiograph was again normal

Second previous admission—On June 7, 1956, he was admitted as an emergency with a month's history of increasing effort dyspnœa and left pleural pain He looked ill and was cyanosed and dyspnœic, with signs of a left pleural effusion A chest radiograph (fig 1) on the same day showed a left pleural effusion, and aspiration yielded 20 ml of grossly bloodstained fluid which was sterile on culture The blood-urea was 36 mg per 100 ml, liver-function tests were normal, plasma-proteins 6 15 g per 100 ml, sputum negative for tubercle bacilli, no occult blood in fæces, Hb 47%, no evidence of iron deficiency on blood-film, and erythrocyte-sedimentation rate (E S R) 115 mm in the first hour (Westergren) He was treated with vitamins ('Abidec') and intravenous iron ('Ferrivenin'), and the chest was aspirated on several occasions, grossly bloodstained fluid being obtained each time He was discharged on Aug 1, 1956, clinically improved but still with a left pleural effusion In view of the history of gastric ulcer, malignancy with pulmonary metastases was suspected, and he was asked to attend for outpatient review When he was seen on Sept 18, his condition was found to be satisfactory and he defaulted from further attendance

Course—Four months before admission in April, 1957, he ceased work on account of general malaise followed by pain in the right loin and a series of upper respiratory infections He remained in bed for three weeks Six weeks before admission he complained of severe right pleural pain which persisted, increasing dyspnœa, and generalised weakness His diet since the onset of his ulcer symptoms (October, 1954) had consisted mainly of carbohydrates and boiled fish, with the exclusion of meat and vegetables, and he had received no additional vitamins since his discharge from hospital in August, 1956 There was no family history of blood dyscrasias

On admission (April 24, 1957) he was ill and dyspnœic with signs of a right pleural effusion There were splinter hæmorrhages under the nails of both hands, a few small bruises on the left leg, and considerable bruising and swelling of the right lower leg He had no teeth and his gums appeared healthy

Investigations—The pleural fluid was grossly bloodstained and sterile on culture, subsequent examinations showed Hb 24–34% in the fluid In the blood, the Hb was 60% (8 9 g per 100 ml), erythrocyte-count 3,410,000 per c mm (colour-index 0 9), and leucocyte-count 4600 per c mm, the red cells showed mild anisocytosis and hypochromasia The bleeding-time was 2 min, Hess' test negative, and prothrombin-time normal The Wassermann reaction and Kahn test were negative, the E S R (Wintrobe) was 52 mm (uncorrected) or 28 mm (corrected for anæmia) in the first hour Fæces (three specimens) contained no occult blood A chest radiograph on admission showed a large right pleural effusion, the left side was clear (fig 2) An ascorbic-acid saturation test showed no excretion until the seventh day

Treatment and further observations—He was treated by repeated chest aspirations, oral iron, and large doses of ascorbic acid His general condition improved quite rapidly, the skin hæmorrhages faded, and his effusion lessened (fig 3) In view of the previous suspicion of malignancy he was transferred for special investigation to Holywood Hall Hospital on Jan 13, 1957 Bronchoscopy (Mr W C Barnsley) was normal A bronchogram showed some crowding and bronchiectasis of the posterior basic segment of the right lower lobe Pleural fluid was reported as containing "several clumps of cells almost certainly neoplastic" An electrocardiogram was normal Hb 83%, platelets not diminished, clotting-time 10 min 15 sec, bleeding-time 4 min 20 sec He was discharged home on July 13

Follow-up—Since his discharge he has been followed up by one of us (W R.) and a chest radiograph on Aug 7 showed that the effusion had completely cleared He continues to have indigestion, and is keeping to his diet but having vitamin supplements When he was last seen on March 3, 1958, his chest radiograph (fig 4) showed a shallow right costophrenic

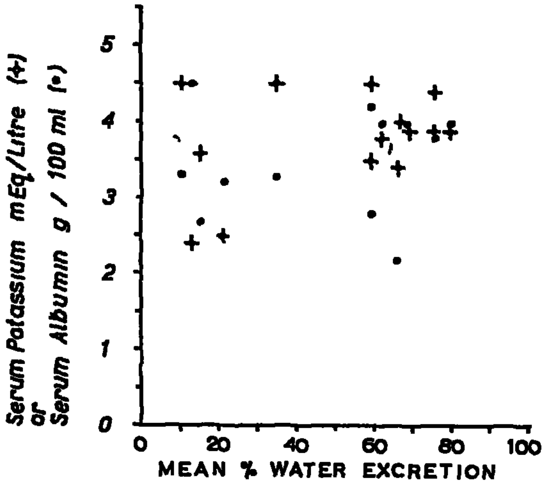

Fig 4—Excretion of fluid in relation to serum-potassium and serum-albumin levels

more particularly those who were more severely ill, but no relationship with diuresis was apparent Similarly, impairment of diuresis was not related to the degree of hypoalbuminuria (fig 4)

Specimens of upper jejunum were obtained from 10 patients with steatorrhœa (in case 6 at laparotomy, in case 13 at necropsy, and from 8 patients by aspiration biopsy) Diuresis was not directly related to either the presence or the absence of mucosal changes, because biopsy specimens from cases 3, 4, 6, 8, and 14 were normal, and those from cases 2, 7, 11, and 12 showed mucosal atrophy

Nocturnal polyuria, with or without œdema of the ankles, was pronounced in cases 7 and 9 (grade II) and 10, 12, and 13 (grade III)—i e, in association with more severe impairment of diuresis

Discussion

Impaired absorption of water, due to the pooling of fluid in the gut during the digestion of food, was emphasised by Wollaeger and Scribner (1951) as the cause of the delayed diuresis in idiopathic steatorrhœa, but we, like Taylor (1955a), found comparable impairments in diuresis under both fasting and non-fasting conditions Furthermore, clinical and radiological evidence of intestinal distension with fluid levels and gas was unrelated to the efficiency of diuresis in our patients

Nevertheless, studies with isotopes have confirmed that the absorption of water from the small intestine is delayed in idiopathic steatorrhœa (Higgins et al 1957) This could theoretically be due to lesions of the small-intestinal muscosa (Paulley 1954, Shiner 1957) Mucosal changes in the small intestine are also present in Crohn's disease and tuberculous enteritis, and they may follow partial gastrectomy (Baird and Dodge 1957) Impaired diuresis, in the present study, was a feature of all these conditions, but it could not be related directly to the severity of the histological lesions found in the small gut, and subnormal responses to water loads were obtained in the absence of demonstrable mucosal changes

A similar impairment of diuresis after the intravenous administration of fluid suggests that altered renal excretion of water was a more important factor than intestinal malabsorption Simple dehydration is unlikely to explain the impaired diuresis, because the same delays in excretion were found in both fasting and non-fasting states, and in most patients there was no watery diarrhœa or other cause of dehydration

Patients with more active disease exhibited the greatest impairment of diuresis, and, in the 1 patient studied, rapid improvement followed successful treatment A subnormal diuretic response to water loading is to be anticipated in many types of serious illness but not to the degree that was found in malabsorption states Anæmia (Taylor 1954b, 1955b) and malnutrition with or without hypoproteinæmia (Sinclair 1948) may influence the renal excretion of water to some extent In the present series severely ill patients had lost the most weight and had the greatest anæmia, but abnormal results also occurred in the absence of anæmia or of malnutrition There was no correlation between diuresis and serum-albumin levels or the amount of fat in the stools This accords with the findings of Cooke (1957), but Taylor (1954a) found a relationship between diuresis and the degree of steatorrhœa

In addition to disordered metabolism of water, faulty absorption of sodium (Newsholme and French 1954) and fæcal loss of sodium and potassium (Cooke et al 1953) have been reported in idiopathic steatorrhœa Cooke (1957) postulated that a renal tubular nephropathy due to depletion of potassium might contribute to the impaired diuresis in idiopathic steatorrhœa No evidence of kidney disease was found in the present study, but we could not fully exclude a nephropathy, and hypokalæmia was sometimes present Cooke failed to influence the diuresis by administering hydrocortisone, in contrast to the improvement coinciding with the use of hydrocortisone in a patient reported by Nabarro et al (1957) These considerations therefore indicate a profound metabolic disorder of both water and electrolytes during relapses in the malabsorption syndrome, possibly implicating adrenocortical or neurohypophyseal function and resembling the abnormal diuretic patterns in cardiac, renal, and hepatic disease

Summary

Diurésis is delayed after the administration of fluid in idiopathic steatorrhœa and in other small-intestine malabsorption states A comparable impairment of diuresis follows both oral and intravenous fluid loads in both the fasting and the non-fasting states

The degree of impairment of the response is more closely related to the severity of the clinical condition than to specific biochemical, radiological, hæmatological, or histological changes, and, as a casual factor, disordered renal excretion appeared more important than malabsorption of water from the intestine

We are grateful to Dr F Avery Jones for advice and for encouragement of these studies, Dr M Shiner for the aspiration biopsies of the jejunum, and Sister M Johnson and Sister M Spire and their nurses for preparing the patients and collecting the specimens

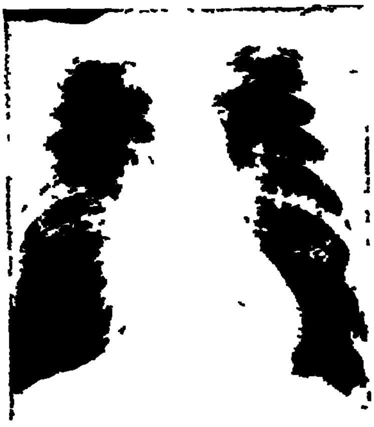

Fig. 1—Case 1: radiograph (somewhat overpenetrated) showing filling of right costophrenic angle and peaking of right diaphragm, fine nodulation of lung fields, most marked in right mid zone; linear shadows on left side not obscured by nodulation, and increased translucency at bases.

Bare wire electrodes are practically never used nowadays, coated electrodes having many advantages. The coatings act as a stabiliser of the arc, a flux, a slag to prevent too rapid cooling, a sheath to exclude air, and a source of certain elements for the weld metal. Common constituents of the coatings include oxides of iron, titanium, and manganese, silicates (such as various clays and felspar), and carbonates of calcium and other metals. The resultant fume is therefore of complicated composition, and iron oxides may constitute a relatively small proportion of it. According to Thrysin et al. (1952) a typical fume, when steel is being welded with neutral coated electrodes, may contain 30–60% of iron oxide, but with basic-coated and other special-purpose electrodes the iron-oxide content may be as low as 16%.

Other common constituents include silicates and the oxides of titanium, manganese, and calcium. The form in which silica exists in the fume does not appear to have been accurately determined, but according to Tebbens and Drinker (1941) crystalline silica is absent. It is believed that, at the temperature of the arc, any free silica that might be produced would combine with the oxides present to form silicates.

Silica and other dusts may arise from extraneous sources. For instance, electric-arc and carbon-arc welders and oxyacetylene burners or cutters working in the fettling-shops of foundries and, less often, in engineering-shops, where castings are cleaned, are exposed to the dust of free silica in the atmosphere of these shops.

Harding et al. (1950) described the pathology of the lungs of a carbon-arc welder who had worked in a steel fettling-shop. The lungs showed areas of mixed-dust fibrosis, and in the hilar glands were well-marked silicotic nodules.

McLaughlin and Harding (1956) described the necropsy and other findings in 5 welders and oxyacetylene cutters employed in iron or steel foundries for ten to thirty-seven years (average 21·2 years). Slight mixed-dust fibrosis was present in the lungs of 3 of these men but was not a factor in the death of any of them.

Charr (1955, 1956) has described the pathology of the lungs of 4 welders: 1 a complete necropsy and the 3 others lung biopsies. He showed that there was slight fibrosis in relation to the iron pigment in 3 of the cases.

Mann and Lecutier (1957) found emphysema and loss of elasticity in a lobe, excised because of a tuberculoma, from an arc welder of twenty-five years' experience whose X-ray film showed "an increase in the vascular markings, accompanied by a fine stippling of nodules 1 mm. in size, scattered mainly throughout the lower two-thirds of both lung fields." The emphysematous portion of the lung had 22% of ferric oxide and the tuberculous portion 13%. On the basis of this complicated case Mann and Lecutier suggest that iron oxide is not inert, and that arc welders' lung is not always innocent and reversible. Prof. J. Gough, who made a large section of the lung, found that the iron deposits were related to and a probable cause of the emphysema. But the larger iron content of the emphysematous portion of the lung compared with the tuberculous portion could equally be ascribed to lymphatic obstruction in the latter, limiting the entry of iron-dust particles into that portion.

We present here the pathology of the lungs of 4 electric-arc welders and 1 oxyacetylene cutter or burner who, so far as we could determine, had not worked in foundries or been exposed to the dust of free silica in other industries. In 2 of the electric-arc welders slight mixed-dust fibrosis was found, and in the other 2 there was no fibrosis, though 1 had been exposed to welding fume for forty-two years before he died as the result of an accident.

Case-reports

Case 1.—An electric-arc welder, who was 69 when he died in 1956, had always worked in engineering-shops, never in foundries. He started welding in 1914, and after 1917 always used coated electrodes usually wrapped with asbestos. He gave up welding in 1943 (after twenty-nine years) and became a club steward; he gave up all work in 1950 because of cough and dyspnœa. He was examined by a pneumoconiosis medical panel in 1950 and in 1953 and was judged to have pneumoconiosis and severe emphysema, but his total disablement was considered not to be due to pneumoconiosis. Radiography of his chest (fig. 1) on April 6, 1955, showed that his skeletal and

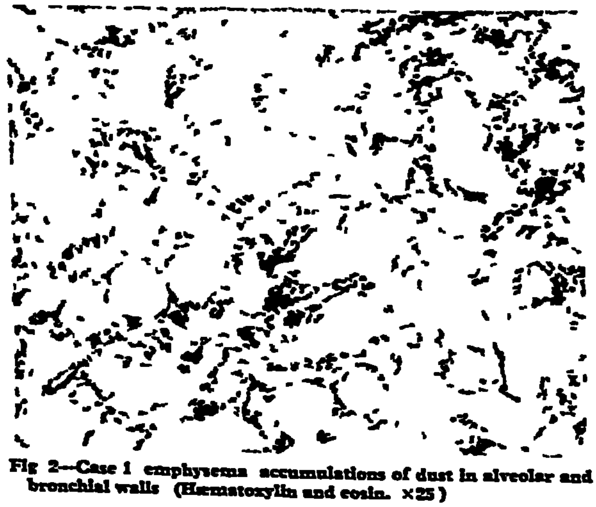

Fig. 2—Case 1: emphysema; accumulations of dust in alveolar and bronchial walls. (Hæmatoxylin and eosin. ×25.)

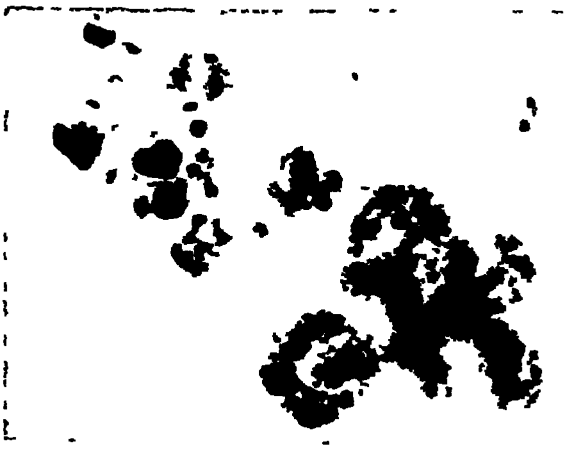

Fig. 3—Case 1: "curious body" in lung (probably an aggregate of cells containing hæmosiderin). (Hæmatoxylin and eosin. ×680.)

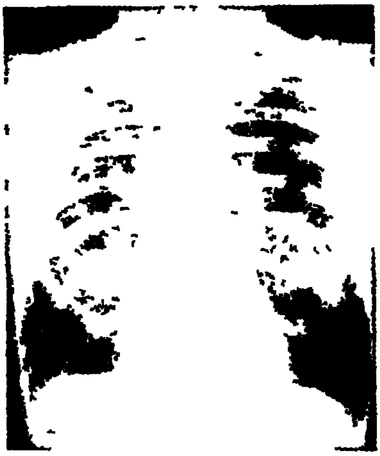

Fig 7—Case 4 radiograph of chest showing reticulation with micro-nodulation over both lung fields, more marked in mid-zones, with linear shadows obscured by the nodulation, and some increased translucency at bases

(fig 5) Apart from the bleeding, this was essentially a normal lung

Comment.—Little pigmentation and no fibrosis of the lungs were found after about forty years' electric-arc welding

Case 3—A man, aged 61, had been an electric-arc welder for more than thirty years for a city corporation, working mainly on tram-lines He collapsed and died on an omnibus After a necropsy, the cause of death was given as "myocardial fibrosis, coronary atherosclerosis"

Necropsy findings—To the naked eye the lungs were apparently normal, apart from congestion They showed only slight focal pigmentation and no fibrosis The hilar lymph-nodes were slightly enlarged, black, and soft. A large section of lung showed only the slightest traces of simple pneumoconiosis and might well be accepted as normal for a man who had lived for sixty years in a dirty industrial city (fig 6) There was slight fine emphysema, not focal in type, at the margins of the lower lobe Microscopically the lungs showed congestion and œdema with very slight mixed-dust fibrosis The hilar lymph-nodes showed a little fibrosis unrelated to pigment Chemical analysis gave, as percentages of weight of dried lung, ash 3 85, total silica 0 15, free silica 0 006, and iron (as ferric oxide) 0 5

Comment—There was insignificant fibrosis after more than thirty years' welding

Case 4—A man, aged 63, died in 1956 From 1907 to 1918 he served his apprenticeship as a boiler riveter and worked casually on ship-repair work as such until he changed over to electric welding in 1918 From 1918 to 1926 he worked on board ships, using covered rods and never doing any carbon-arc welding or gas welding For the next ten years he was a welder of boilers, and about 80% of his time would have been spent in enclosed spaces, the only precaution against fumes being the use of a compressed-air pipe to ventilate his working-compartment For the next ten years he worked to a greater extent on ship repairs, and probably only 50% of his time would have been in enclosed spaces A lot of the work would have been on painted metal, and less than 5% on galvanised metal In general the welding would not have been of heavy type, the usual current would be 200 amp, with a maximum of 300 amp and the average thickness of the electrodes would be 6-gauge.

He had pleurisy at the age of about 13 years For the last ten years of his working life he had bronchitis and had been off work several times In January, 1946, he was off work for three weeks with bronchitis, he returned to work for four days and was then ill with pneumonia He had not worked since He made a claim to the Silicosis Board in November, 1946, and was examined by the panel in January, 1947 The clinical findings then were those of an unresolved pneumonia at the right base There was no clubbing of the fingers, and his general condition and exercise-tolerance test were considered sufficiently good for him to do light work A certificate was refused Radiography in 1947 showed normal skeletal, heart, and diaphragm shadows and no increased hilar shadows, reticulation with a micronodulation throughout both lungs, mainly in the mid zones, and increased translucency at the bases suggesting emphysema Another radiograph (fig 7), taken in 1954, showed no alteration in the picture.

Necropsy findings—Dr D M McClure reported "Dense pleural adhesions are present on both sides The lungs are fairly bulky, and show well-marked vesicular emphysema without the formation of large bullæ On section the lungs show fine diffuse nodularity of fibrous type These fibrous nodules are very small and in no instance coalesce into large masses At the most they are just palpable, but they are very numerous and uniformly distributed in all areas The picture is quite distinct from that seen in typical coalminers' pneumoconiosis, but it is none the less a process of pneumoconiotic type Chronic bronchitis is also prominent The cause of death was given as chronic bronchitis and emphysema associated with fine diffuse pneumoconiotic fibrosis" Sections from the lungs show generalised emphysema and probably some focal emphysema associated with small areas of mixed-dust fibrosis in which collagen is present (figs 8 and 9)

Comment—There was slight but definite mixed-dust fibrosis in the lungs of a man who had done arc welding for twenty-eight years, mostly in enclosed spaces Whether this fibrosis played any significant part in his disability and death or not we consider to be very doubtful The main, if not the sole, cause of his disability was chronic bronchitis and emphysema Possibly these conditions may have been occupational in origin, caused by paint fumes, constituents of the rod coverings, or oxides

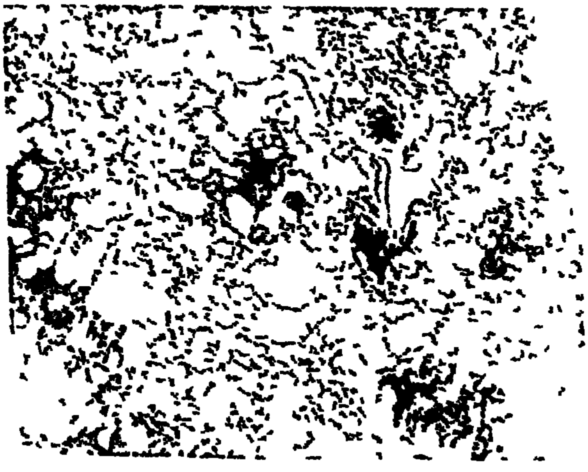

Fig 8—Case 4 small areas of mixed-dust fibrosis; emphysema, generalised and possibly also focal. (Hæmatoxylin and eosin ×8.)

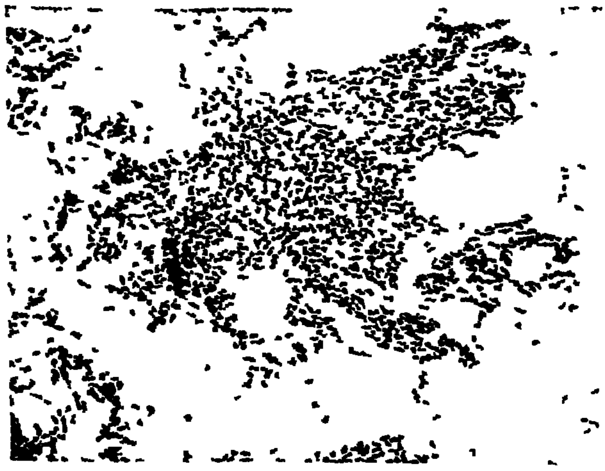

Fig 9—Case 4 nodule of mixed-dust fibrosis (Hæmatoxylin and eosin. ×32)

of nitrogen, but, on the other hand, they may have originated in early life, when he had pleurisy

Case 5—A man, aged 37, had been employed as an oxyacetylene cutter in an engineering works for six years He then did odd jobs for six years, followed by six years in the Army, and then a further three years' cutting He was examined by a mass miniature radiography unit about two months before his death, and " no significant change " was found in his film He committed suicide by hanging

Necropsy findings—Except for some general browniness, his lungs appeared normal to the naked eye Microscopically there were congestion and œdema, very little dust, and no fibrosis Chemical analysis gave, as percentages of the weight of dried lung, ash 1 95, total silica 0 06, free silica 0 03, iron (as ferric oxide) 0 54

Comment—No fibrosis was found in the lungs of a man employed for nine years as an oxyacetylene cutter

Discussion

It is generally believed that the inhalation of iron-oxide dust does not lead to fibrosis in the lungs or produce disability, but that the retained dust gives X-ray shadows that may be indistinguishable from fibrotic pneumoconiosis The condition is usually called " siderosis " (Doig 1949, McLaughlin 1950, 1951) Welders and oxyacetylene cutters commonly inhale iron-oxide fume, and not infrequently show shadows in X-ray films of their lungs However, few welders are exposed only to iron oxide some of them work in places such as the fettling-shop, where there is a mixed silica dust produced by other operations, most of them nowadays use rods coated with various materials, the metal which they work on may not be iron or may contain metals other than iron, and if they work in enclosed spaces, oxides of nitrogen and possibly other gases may irritate the respiratory tract

When one recalls how difficult it may be to ascertain what employment a man may have had during every part of a working life of forty or more years, and to imagine the conditions under which he may have worked many years before, it is evident that great caution must be used in interpreting the cause of any changes found in the lungs at necropsy This, however, does not apply when the only findings are siderosis with no fibrosis or only microscopic fibrosis In such cases one can say with confidence that iron-oxide dust has not produced any significant pathological lesion

So far as we have been able to ascertain, none of the 4 electric-arc welders described above had been exposed to any obvious risk from silica dust, but all had used coated electrodes, and case 4 had been exposed to fumes from burning paint Cases 1 and 4 showed very slight mixed-dust fibrosis with nodules that were just visible and palpable after twenty-nine and twenty-eight years' welding respectively, case 3 showed mixed-dust fibrosis of insignificant degree and only found microscopically after more than thirty years, and case 2 had no fibrosis after forty years' welding In none of them do we believe that mixed-dust fibrosis was responsible for death or produced any recognisable disability

The only oxyacetylene cutter showed slight accumulation of dust in his lungs and no fibrosis, but he had worked as a cutter for only nine years, with a twelve-year break between two periods of cutting

We consider that it is established beyond doubt that considerable quantities of pure iron oxide can be inhaled and remain deposited in the lung tissue without producing fibrosis Slight degrees of fibrosis may be present in the lungs of some electric-arc welders, we believe that this has not been caused by iron oxide but by other constituents of the welding fume, or possibly by some of the gases evolved In our experience the degree of fibrosis present, even in welders with long experience, has not been sufficient to cause any disability More severe degrees of fibrosis amounting to mixed-dust pneumoconiosis, associated in some cases with disability, have, in our experience, occurred only in welders exposed to extraneous sources of silica, such as that found in fettling-shops of foundries

Summary

Details are given of 4 electric-arc welders and 1 oxyacetylene cutter who came to necropsy These men had never worked in foundries or been exposed, so far as we could find out, to a silica-dust risk 2 of the welders showed very slight mixed-dust fibrosis in their lungs, 1 only microscopically visible fibrosis, and the 4th none The lungs of the cutter showed no fibrosis In those cases in which emphysema was present it was not usually of the focal type

Pure iron-oxide dust does not produce fibrosis of the lungs When fibrosis is found in the lungs of welders and others exposed to iron-oxide dust, it is probably due to other factors, including other substances inhaled with the iron oxide

We are indebted to Dr A H Cameron for the lungs of case 1, to Dr D M McClure for the necropsy report on, and for sections from, case 4, Mr R Conroy for the photomicrographs, and Dr J C McVittie, of the *Ministry of Pensions and National Insurance*, for the X-ray films of cases 1 and 4 and for help in many other ways

CONGENITAL CURLY TOES

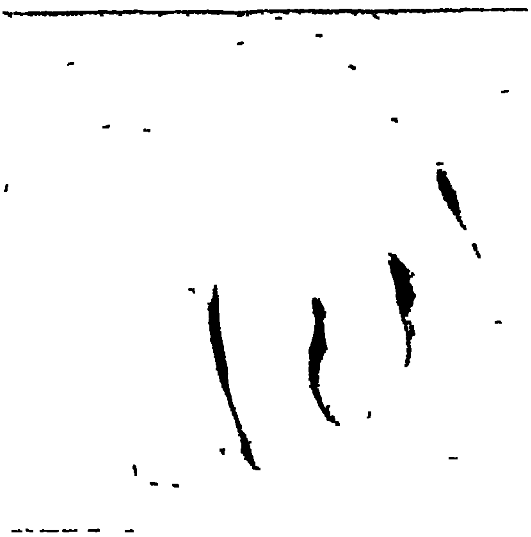
AN INVESTIGATION INTO THE VALUE OF TREATMENT

Rodney Sweetnam
M A, M B Cantab, F R C S
LATE ORTHOPÆDIC REGISTRAR, THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON, W C 1
From the Hospital for Sick Children, Great Ormond Street, and the Victoria Hospital, Tite Street, London

Deviation of one or more of the middle three toes is a common congenital abnormality The mother, anxious that her child should be normal in every way, seeks medical advice as soon as the deformity is noticed, and, according to whom she consults, she will be advised either that the toes will straighten themselves with growth or that some form of treatment is required The treatment usually advised consists of adhesive " over-and-under " strapping connecting the affected toe to its neighbours, in this way an attempt is made to hold the deformed toe in a corrected position

It was felt that this diversity of opinion concerning the value of, and even the necessity for, treatment warranted investigation, particularly since a thorough search of the literature revealed no account of the prognosis of this deformity either when left alone or treated This investigation is an attempt to remedy this deficiency

No consideration has been given to the common and well-documented condition of dorsal displacement of the little toe, in which the little toe overlies its neighbour, or to congenital hammer toe Both deformities have already received ample attention and are well described in standard textbooks—e g, Wiles (1955) The present investigation was concerned with congenital deviation of the third and fourth toes, more commonly the former, but occasionally



Congenital curly toes

also the second toe The toe is adducted and curled under its neighbour (see figure) The deformity is a mixture of adduction and flexion, mainly at the terminal joint, but also in the proximal, and is combined in the more severe cases with rotation of these joints, the nail coming to lie towards the lateral side Commonly two or even three toes are affected, and often both feet are involved

Trethowan (1925) described the condition in detail and believed that conservative treatment was successful "in the slighter and earlier degree of deformity" but emphasised that such treatment must be applied "with patience and assiduity" There has been no further contribution to this subject in the English literature since then

Investigation

The relatively trivial nature of the condition made follow-up of patients difficult, particularly because they had all been treated in infancy and could not be examined for the purpose of this inquiry until adolescence, the average age being 13

Fifty feet were available for examination (table I), the series is almost evenly divided between treated and untreated children

The treated children had all had the deformity held in attempted correction by means of over-and-under strapping for many months, the average being thirteen In only three children was this treatment started after the age of 2 years

TABLE I—COMPOSITION OF SERIES EXAMINED

No of children	Bilateral	Unilateral	Average age at follow-up (yr)	Average duration of treatment (mos)
29	21	8	13	13

TABLE II—RESULTS IN TREATED AND UNTREATED GROUPS

—	No of feet examined	No improved	No unchanged
Treated	21	5 (25%)	16 (75%)
Untreated	29	8 (27%)	21 (73%)
Total	50	13 (26%)	37 (74%)

When the children were examined in adolescence, the position of the toes was compared with the severity of the deformity when first seen, as recorded in the hospital notes If there was any doubt whether or not there had been improvement, the mother's opinion, if definite, was accepted Since this method of assessment was used in both the treated and the untreated children it does not detract from the validity of the results

Results and Conclusions

In no foot treated or untreated was any deterioration in the deformity found Growth of these crooked toes might have been expected to increase the apparent deformity, but this was not seen The number showing improvement, about 25% of the total, was almost evenly divided in proportion to the numbers in the treated and untreated groups (table II)

Eleven children (22%) had a known close relation similarly affected More detailed inquiry into this feature, together with examination of relations, would probably reveal a larger proportion The lack of symptoms in most cases would be unlikely to arouse attention among members of a family

None of the children examined had any symptom related to their curly toes, indeed the majority had forgotten that they had such an abnormality until the "follow-up" letter arrived

This inquiry has shown that over-and-under strapping has no significant effect on the outcome of this deformity of the toes However, since a quarter of the untreated cases improved and none of the remainder deteriorated, it is doubtful whether any form of treatment is worth while

The follow-up was not long enough to show whether symptoms occur in later life, that they did not do so by adolescence is no criterion However, from the relatively mild deformity and natural tendency for the toes of an adult to fit together by mutual pressure, it seems unlikely that troublesome symptoms would arise in many patients In fact, painful conditions of such curly toes are seldom seen in an orthopædic clinic, and, in any case, if they arise, the toe can be straightened by a simple operation in the outpatient department.

Undoubtedly many parents obtain satisfaction from knowing that something is being done to correct their child's "deformity" Perhaps this warrants recourse to treatment, but in most cases a simple explanation of the facts will save all concerned much time and valueless effort in treating a condition which requires no treatment.

Summary

An investigation into the value of treatment of congenital " curly toes " is described

The usual method of treatment with over-and-under strapping is both without effect and unnecessary

This investigation was undertaken at the suggestion of Mr G Lloyd-Roberts and it is a pleasure to acknowledge his kind help and advice and to thank him for allowing me to examine his patients I also wish to thank Mr R H Young for permission to examine children under his care at Victoria Hospital, Tite Street, and Miss B Kennedy, M C S P, for her generous help

AEROPHAGY OF EFFORT

A SYMPTOM OF CORONARY-ARTERY DISEASE

GEOFFREY BOURNE
M D Lond, F R C P
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL, LONDON, E C 1

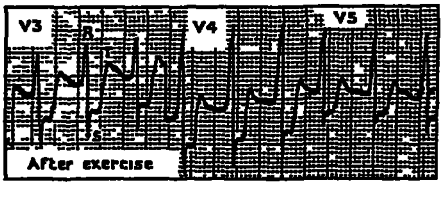
THE way to a man's heart is said to be via his stomach Symptoms often follow the same route Palpitation is frequently gastric in origin, angina of effort is often intensified immediately after a meal, flatulence is apt to follow the termination of an attack of paroxysmal tachycardia or indeed of anginal pain, and, finally, lesions of the œsophagus, and dysfunction of it, are known sometimes to simulate very closely the pain of myocardial infarction or of angina of effort

Berman (1957), in a paper entitled Dyspepsia of Effort, emphasises the relationship between exercise and gastric symptoms but does not specifically refer to aerophagy, although in three instances the dyspepsia overshadowed the anginal pain

The present case is a further gastrocardiac example of a type hitherto undescribed

A man, aged 65, began to have typical intermittent claudication in May, 1955 Previously he had been able to walk 8–10 miles a day without symptoms On clinical examination his cardiovascular system was normal except for a slightly raised diastolic blood-pressure (158/100 mm Hg) and some coolness of his legs and feet Electrocardiography showed a Q wave in leads III and VF The T wave was flat in lead III but normal in VF Deep inspiration diminished these abnormalities Radiologically the heart was normal in size and shape When he was seen in June, 1956, and again in July, 1957, his walking had improved He was otherwise symptomless The physical state and the electrocardiogram were unchanged

In August, 1957, he first noticed, and complained bitterly of, belching, accompanied by a feeling of tightness in his chest He associated the symptoms with walking and with excitement or emotion They would come on after he had walked about 50 yards and were absent at rest When he was examined in October, 1957, there was no change in his physical state, but he produced at intervals the noisy eruptive self-satisfying single belch of typical air-swallowing This recurred like an infrequent minute-gun during the examination A slight apical systolic murmur was now audible There was no other change in his resting clinical state or in the resting electrocardiogram An orthodiagram showed the heart to be a little larger His œsophagus and stomach were investigated radiologically by Dr George Simon and were found to be normal The patient was given a carminative mixture and advised about his method of eating The mechanism of his air-swallowing was also explained



S-T depression very well marked in leads V_3, V_4, and V_5, considerably more than could be accounted for by associated tachycardia

He was seen again on Nov 18, and this time the electrocardiogram was taken both before and after exercise Exercise produced depression of S-T from V_3 to V_5 (see figure) associated with much belching In view of the recent onset and the increasing severity of his symptoms he was treated by three weeks' rest in bed and was given a course of anticoagulant therapy He improved, but the symptoms persisted in a lesser degree

The psychological background is interesting During the first world war the patient went overseas and returned home with a functional visual disability He was unable to face the light, and a short spell of reading made him mentally confused He consulted several ophthalmologists both in this country and on the Continent Mr E H Cameron, of Edinburgh, reported on him on Nov 29, 1957, as follows

> " He has been coming to see me at intervals since 1944 and has always been difficult to deal with satisfactorily He had seen Dr A H H Sinclair here and the late Professor Ballantyne in Glasgow before coming to me, and told me that some years ago Dr Sinclair had told him he had ' optic neuritis ' I could never myself find any abnormality about his eyes, except a low refractive error and a low hyperphoria His corrected vision has always been 6/6 partly with each eye, and I have never been able to find any field changes His main complaint has been reading difficulty For this I could never find any evident cause and was forced to regard it as psychological "

The psychological factor seems to have been the link between the cardiac cause and the gastric manifestation

A SELF-COMPENSATING PNEUMATIC TOURNIQUET

C S JONES
M B Cape Town
A F GREGORY
From the Department of Anæsthesia, Groote Schuur Hospital, and the University of Cape Town

SURGERY of the limbs is greatly facilitated by the bloodless field which a tourniquet produces, this is often achieved by using the pneumatic cuff of a sphygmomanometer, particularly for surgery of the arm in adults and all the limbs of children The ordinary sphygmomanometer tends to leak from its connections and from the deflating valve, and must be watched constantly and attended to regularly if adequate pressure is to be maintained in the cuff

We have used the systems described herein and sketched in the diagrams and find that they keep a constant pressure in the cuff without any attention

The simpler system (fig 1) utilises an Adams reducing valve from an anæsthetic machine This valve ordinarily reduces the pressure in an oxygen or a nitrous-oxide cylinder to about 4–6 lb per square inch (which is equivalent to a pressure of 200–300 mm Hg) and can be set to various pressures within its working range by adjusting the tension of a spring seated against the diaphragm of the valve This adjustment is coarse, therefore, if it is used for inflating a tourniquet from a cylinder of medical gas, the pressure exerted by the tourniquet is not precisely controlled. However, the volume of gas used is limited to that required to inflate the cuff and to make good any leakage from the cuff and its connections.

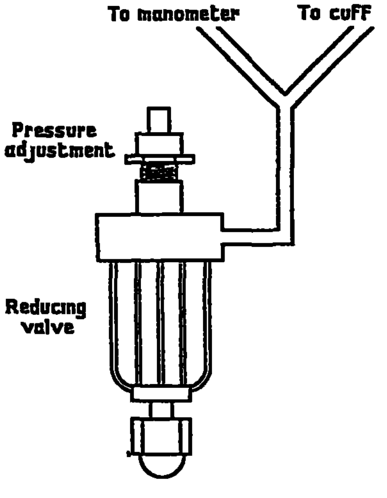

Fig 1—The simple system with coarse pressure control and low gas consumption

The more complex system (fig 2) also utilises a high-pressure gas and a reducing valve, but in this instance the valve is set to deliver greater pressures, say 8–10 lb per square inch (about 400/500 mm Hg), and there is a constant leak built into the system between the tourniquet and the control mechanism. A constant flow of gas is led from the reducing valve to the tourniquet, the volume flow being controlled by a needle valve on the low-pressure side of the reducing valve. By balancing this flow of fresh gas against the constant leak of gas, any desired pressure can be achieved in the tourniquet, and can be maintained as long as the source of gas lasts. The gas flows are small, but much more gas is used than in the simple system. However, the pressures in the cuff can be adjusted to within 1–2 mm Hg of the desired pressure.

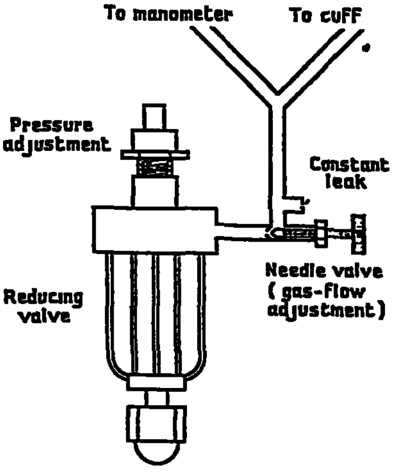

Fig 2—The more complicated system with fine pressure adjustment but larger gas consumption

It is advisable to use a mercury sphygmomanometer to monitor the pressures in the tourniquet, and, if the volume of mercury in the reservoir is adjusted, the manometer becomes a safety-valve as well as a measuring device, permitting gas to escape from the system if the pressure is raised to excess.

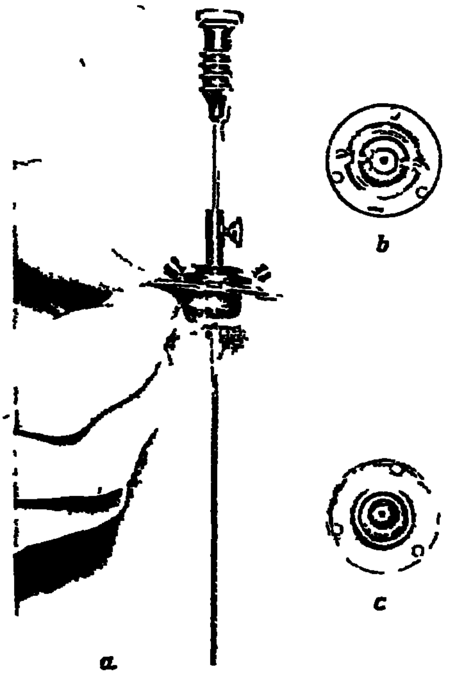
Both systems compensate for all but the grossest leaks. The constant leak also allows its system to compensate for increased pressures within the tourniquet—e g, from a constricting towel or bandage.

Our pilot model has been in satisfactory use for 6 months.

New Inventions

CUP-AND-BALL CHEMOPALLIDECTOMY APPARATUS

CHEMOPALLIDECTOMY and chemothalamectomy are now established procedures for the treatment of selected cases of parkinsonism and other hyperkinetic disorders. Most techniques in current use are complex, tedious and time-consuming. The cup-and-ball apparatus has been designed to simplify these procedures and to save time.



a Lateral view of the apparatus with the needle in place. *b* View from above. *c* View from below.

As with other methods, the target (globus pallidus or ventrolateral nucleus of the thalamus) is first located by means of pneumoencephalography. A burr-hole is then made, 13 cm from the nasion and 5 cm from the midline, and the cup-and-ball is fixed into the burr-hole with three pins which pass through the rim of the apparatus into holes drilled into the bone. A guarded drill of smaller size than the pin is used. A brain needle is passed a short distance into the brain through the hole in the ball in the approximate direction of the target (the ball can be fixed or moved by tightening or loosening the screws). Anteroposterior and lateral X-ray films are taken and any adjustments of the direction of the needle are estimated and carried out. The needle is then pushed inwards to the correct depth and the adjustable collar is fixed by means of the thumbscrew. The distance of the collar along the needle is measured for future checking. A small quantity of procaine is injected. If the point of the needle has reached the target, contralateral involuntary movement and rigidity should be relieved or greatly reduced. The scalp is then sutured except over the centre of the ball.

As the ball is fixed by screws, and the required depth of the needle is known, the needle may be removed and replaced on subsequent occasions for injection of absolute alcohol without further radiography. When the course of injections is finished the wound is opened, the apparatus removed, and the scalp resutured.

The apparatus is made by Lewis Bros London.

Reviews of Books

The Matrix of Medicine

Editor NICOLAS MALLESON, M D , M R C P , University College, London London Pitman Medical Publishing Co 1958 Pp 234 45s

THE theme of this book is the interplay of medical practice with the patterns of living in our community It seeks to explore some aspects of the social interfaces between the profession and the laity, whether the latter be the works foreman with a grouse or the anthropological studies of a nation It is a contemporary look around by sixteen different doctors peeping over the walls of their specialties, and meditating on what they see pass by In some respects it may be a ephemeral record, in some a renewed witness of eternal verities, for at the best it can be only a reflection of the outside world from the eyes of the sympathetic. It would be a mistake to think of medicine embedded in the social matrix in too concrete a metaphor, and the contributors emphasise the essential onward movement of the matrix and its aggregates, moving at irregular speeds and distances, more like moraines in a glacier, constantly altering each others' shapes and behaviour at the changing interfaces

It is in this way that each of the sixteen doctors looks across his own periphery General practice, public health, occupational health, hospital practice, and medical education, may all cherish their internal disciplines, but it is refreshing to see their exponents make a critical survey of their own impact upon the community This is a thought-provoking series of essays, to be dipped into at quiet moments, for most of us need to hear from time to time the whisper, *know thyself*

Intestinal Obstruction

CLAUDE E WELCH, M D , visiting surgeon, Massachusetts General Hospital, and clinical associate in surgery, Harvard Medical School Chicago Year Book Publications London Interscience Publications 1958 Pp 376 79s

IN this admirable book, Dr Welch has achieved the laudable aim of packing a small volume with information yet making it readable Its tone breeds confidence, for the chapters are studded with practical instructions which can come only from wide experience In the chapter on intubation for example, the author is not content with the usual information, for he also considers the complications everybody has encountered but seldom reads about knot formation, inability to withdraw the tube, rupture of the mercury-filled balloon are some of those mentioned It is refreshing too to read the categorical statement that it may be very difficult to place the tip of a Miller-Abbott tube in the pylorus There is a fine chapter on replacement therapy and a full bibliography The book will give excellent guidance at all stages of a surgical career, and it reflects great credit on the Massachusetts General Hospital

An Introduction to Psychopathology

D RUSSELL DAVIS, M A , M D , M R C P , D P M , reader in clinical psychology, University of Cambridge London Oxford University Press 1957 Pp 388 30s

As psychologist and psychiatrist, Dr Russell Davis is well equipped to write a book on this unsettled subject In a revealing passage in his opening chapter he gives due weight to clinical data as sources of evidence but suggests that many difficulties now besetting psychopathology are attributable to the emphasis, in contemporary British psychiatry, on somatic manifestations and constitutional causes of mental disorder This novel view seems at variance with the current dominance of psychoanalytic theory in psychopathology Dr Russell Davis depends not on the methods of psychoanalysis but on correlation and experimental procedures His exposition is lucid and informative, and ranges widely besides familiar themes, such as experimental neurosis and the effects of brain damage, he has chapters dealing with ecological factors, recent behaviour theories, and other biological aspects of psychopathology He adduces much evidence from the literature of the subject but does not examine it rigorously, nor do justice to the extensive German contributions he does not include Jaspers' unrivalled text in his list of about 300 references

Reflexogenic Areas of the Cardiovascular System

C HEYMANS, M D , professor of pharmacology, University of Ghent, E NEIL, M D , D SC , John Astor professor of physiology, University of London, Middlesex Hospital Medical School London J & A Churchill 1958 Pp 271 56s

THIS book is full of interesting and useful information for those who specialise in the study of the cardiovascular system and for laboratory workers concerned with the reactions of any organ, with the exception perhaps of those who study isolated tissues parted from the circulation The reflexogenic areas are not only concentrated in the carotid and aortic regions, similar sensory endings are distributed widely The reader is reminded too of the considerable activity of veins, both large and small, their supply of muscle may appear meagre, but the pressure against which the muscle must contract is low The importance of constriction of the veins probably lies in the modification of venous capacity, rather than in changes of resistance to flow

The first section of the book concerns the arterial baroreceptors, and the second the chemoreceptors, and each section begins with an account of the minute anatomy of the sensory areas A third section is devoted to the cardiopulmonary reflexes The subjects are discussed from every angle methods of study, general effects of stimulation, the local effects in organs of the general vascular response, the effects of anæsthetics and other drugs, and similar reflexes arising in parts other than the circulation.

It is clear that the chemoreceptor system has many facets of interest It is of direct importance in all considerations of respiratory control, whether in eupnœa, exercise, hypercapnia, or anoxia Thus this part of the book will appeal to the specialist in respiration, and so too will the third section

Although the baroreceptors directly affect the circulation and the chemoreceptors more directly concern respiration, one system cannot be affected without modification of the activity of the other and this mutual interdependence is discussed A small section is concerned with work on the still ill-understood volume receptors The last chapter is a miscellany of cardiovascular reflexes of uncertain origin

The condition of the circulation affects the responses of all organs, and the chances are that many workers not directly concerned will find here references or information useful to them, as well as judgment, sometimes sharp, of published work

---

Blood Groups in Man (3rd ed Oxford *Blackwell Scientific Publications* 1958 Pp 377 42s)—The new edition of this now standard textbook by Dr R R Race and Miss Ruth Sanger is actually a few pages shorter than the 1954 edition The text and bibliography have been thoroughly revised and some chapters have been rearranged A new chapter deals with the blood-groups of twins There has been much progress in four years, and new sections are devoted, for example, to the phenotype A_3 and to the surprising amount of new work on the ABH antigens The authors keep to the CDE notation of the Rh blood-groups and do not think that E B Ford's new system of nomenclature can yet be applied in this field Wiener's corresponding symbols are collected in a table for those who wish to use them, and thus avoids repetition in the text Race and Sanger now think that "it looks as if we are nearing the end of the blood-group systems which can be detected by the tests in use up to now" New antibodies are being found to belong to one of the nine established systems Race and Sanger think this is a gloomy prospect, and from the geneticist's point of view they may be right, but the pathologist will surely be cheered by the prospect of some limit to his labours This third edition remains an indispensable survey of everything about blood-groups in man complications, the disturbance to the patient was insignificant and postoperative discomfort slight **Dohlman's**[18] œsophagoscope has a jaw-like slit in the distal end to fix the common wall, and acts as the second electrode while the diathermy forceps are used to perform the operation by stages Two to three interventions at about fortnightly intervals are usually sufficient to give lasting relief **Harrison**[13] obtained good results in his series of 17 patients and found the operation particularly useful in the elderly

In the majority of cases, by the time the patient is seen by the surgeon, the pouch has reached a considerable size and symptoms are pronounced Total one-stage resection of the sac with careful repair and antibiotic cover is usually regarded as the treatment of choice in reasonably fit patients There is a place for diathermy division of the septum between the diverticulum and the œsophagus, especially in the frail, ill, and elderly patient, but this should not be undertaken by the occasional œsophagoscopist, and it is no substitute for diverticulectomy, which obviates the necessity for repeated admissions and the risks (admittedly small) of infection, hæmorrhage, or malignancy supervening in the remaining pouch With modern surgical and anæsthetic methods, ever fewer patients are unsuitable for a single-stage excision of a pharyngeal pouch

Annotations

PROGRESS IN RESEARCH

From the many research studies which the Medical Research Council supports, some each year are selected for review in its annual report Each report thus contains a small collection of authoritative essays, which are readable and up to date and do not confine themselves to work done under the Council's auspices Because the essays could obviously be read with advantage and pleasure by a great many people—especially practising doctors—who would not normally buy the full report, the Council has once again had them reprinted, under the title of "Current Medical Research" This year's issue[1] covers the following fourteen topics

The Architecture of a Protein Molecule
The Development of Respirators[2]
Influenza in 1957
"New" Viruses of the Respiratory and Intestinal Tracts
Viral Interference and the Substance "Interferon"
The Changing Pattern of Serological Tests for Syphilis
The Spinal Cord in Poliomyelitis
Community Surveys in the Study of Rheumatoid Arthritis
The Mechanism of Fever
5-Hydroxytryptamine (HT)
Female Sex Hormones and their Quantitative Estimation
Experimental Studies on Radiostrontium
Experimental Leukæmia
Genetics of Eye Disease

More detailed and comprehensive information about the work now proceeding with the Council's help will be found in the report itself[3] In the year 1956–57, ended last September, its establishments consisted of the National Institute for Medical Research, the M R C laboratories in the Gambia, 44 research units, and 21 research groups, and it was also supporting research at cancer institutes From public funds in the financial year 1956–57 it spent £2,541,549 on ordinary account and £51,230 on non-recurrent account, compared with £2,325,430 and £76,226 in the previous year Of this money 19 6% was spent on the National Institute for Medical Research, 58 8% on research units, groups, and external staff, 7 8% on special grants, and 8 7% on temporary research grants and training awards The income from benefactions, which are gratefully acknowledged, was £115,785 For the financial year 1957–58 Parliament voted a grant-in-aid of £2,680,500, a supplementary grant-in-aid of £95,000 (necessitated by pay awards and other obligatory commitments arising during the year), and £37,500 on non-recurrent account The cost of the Public Health Laboratory Service, which is administered by the Council, is met separately by the Ministry of Health

The members of the Medical Research Council are

The Earl of Limerick (chairman), Sir Geoffrey Vickers (treasurer), Mr Richard Fort, M P, Sir George Pickering, F R C P, Prof Bradford Hill, Prof G F Marrian, Prof R C Garry, F R F P S, Mr H J Seddon, F R C S, Prof G Payling Wright, F R C P, Dr Denis Hill, Prof C H Stuart-Harris, F R C P, and Prof A A Miles, F R C P, with Sir Harold Himsworth, F R C P, as secretary

The Clinical Research Board consists of

Sir Geoffrey Jefferson, F R C S (chairman), Sir Charles Dodds, F R C P, Sir Arthur Gemmell, F R C O G, Dr Denis Hill, Prof R B Hunter, F R C P E, Prof C F W Illingworth, F R C S E, Sir George Pickering, Mr Seddon, Dr W P H Sheldon, Professor Stuart-Harris, and Prof B W Windeyer, F R C S, with Dr F J C Herrald as secretary

THE CHRONIC RESPIRATOR PATIENT

Of late years the treatment of patients with respiratory paralysis from whatever cause has progressed remarkably, and as a result patients with poliomyelitis have survived very severe attacks but have been left with permanent respiratory weakness The total number is not large, but it will increase each year until vaccination against poliomyelitis is available to those beyond adolescence, for it is in young and middle-aged adults that poliomyelitis is most severe and leaves most permanent damage Despite the relatively small number of these patients, they constitute an important clinical and administrative problem, for they make heavy demands on nursing and medical staff

Dooley[1] has reviewed the long-term care of patients who require artificial aid to respiration, basing his figures on a review in Britain in June, 1956 At the upper end of the scale are those who need assistance with respiration for part of the day or perhaps only at night, and Dooley records such a patient who was a house-physician in a London teaching hospital, travelling about the hospital in an electrically operated chair For this type of patient a cuirass or a breathing-jacket is excellent, the principal disadvantage being that some patients find them irremediably cold For the most severely paralysed—those who at best can breathe unassisted for a few minutes—the cuirass and the breathing-jacket are not suitable, and these patients are either nursed in a tank respirator or have a tracheotomy and are given artificial respiration by intermittent positive pressure In either case their spontaneous breathing may be much improved by glossopharyngeal ("frog") breathing Even if these patients have very little power in their limbs it is quite wrong to suppose that nothing can be done for them With suitable apparatus they can read, turning over the pages with an electric switch operated, if necessary, by the chin Electric typewriters are so light to operate that those with

very weak upper limbs can use them, and if even this is not possible they can be operated by a rod held in the mouth Quite ambitious pictures have been painted with a brush held in the mouth

Such patients can be treated at home provided that they can be supervised, and the ability to go about the outside world in general and home in particular provides a greater boost to their morale than anything else There are some differences of opinion on how this is best achieved Undoubtedly, if a patient has a tracheotomy in the acute stage it should be closed when he recovers enough power to breathe spontaneously for several hours a day But it is less certain whether tracheotomies should be closed in those who remain permanently with complete, or very severe, respiratory paralysis and can breathe spontaneously for only a few minutes One policy is to close the tracheotomy and treat the patient in a tank respirator, the advantage of this lies in the reduced risk of pulmonary infection The alternative is to maintain the tracheotomy, giving artificial respiration by intermittent positive pressure, the danger of pulmonary infection may be counterbalanced by the greater ease of treating this, since secretions can so readily be aspirated from the chest The question is still unresolved, but possibly the decisive factor will be mobility Although it is possible to travel extensively in a tank respirator it is by no means easy to do so, and air travel is virtually excluded With intermittent positive-pressure respiration, on the other hand, a respirator which has a 12-volt motor, such as the Radcliffe Respiration Pump, can be housed with an accumulator that will last 24 hours on a shelf attached to the back of a wheelchair This enables the patient not only to get about in the neighbourhood of his home or hospital, but even to visit places of entertainment The ease with which such patients can travel by air has been demonstrated when Britons who have contracted poliomyelitis in Africa or the Far East have been flown to England

When a patient with respiratory weakness leaves hospital it is essential that he should know where to turn for immediate help if he gets into difficulties of any kind In most parts of the country there is a service for bringing to hospital people with acute respiratory paralysis, and usually these teams are most suitable for giving assistance also to more chronic patients

TREATMENT OF RHEUMATOID ARTHRITIS WITH GOLD

THIRTY years after the first account of the use of gold salts in the treatment of rheumatoid arthritis [1] [2] their place is still not firmly established Several careful studies have provided weighty evidence that gold can induce a remission, but their conclusions have not been universally accepted, and the question is now being submitted to the test of a statistically controlled clinical trial in this country

Those who accept that gold is effective have to choose a course of treatment calculated to produce a good response with the minimum risk of toxic effects The commonly used homœopathic doses, unlikely either to influence the disease or to produce signs of toxicity, are clearly not the solution, and a report from Philadelphia[3] supports the belief that the dosage of gold salts should be tailored to the needs of the individual patient Starting from the premise that gold can induce a remission, but that some patients are more resistant to treatment than others, Smith et al [3] sought to explain differences in response by variations in the rate of excretion of gold in the urine Measurements of excretion led them to the conclusion that a predetermined dosage may fail to be effective because the patient excretes gold unduly rapidly, or may quickly lead to toxic effects if excretion is less than normal Differences in the duration of remission are due, they find, to the same causes Treatment must be designed to achieve an effective accumulation of gold in the body by giving a weekly dose which exceeds the amount excreted by the kidneys and by other routes Normally patients receiving weekly injections of 25 mg of gold secreted about a seventh of this amount in the succeeding week, one patient excreted 28% of each dose in the week after injection, and did not respond until the dose was raised to a point at which the excretion-rate amounted to only 14%

In routine practice it is not feasible to regulate the dosage of gold by measuring its excretion, and Smith et al suggest a method whereby the patient's response to treatment can be used as a guide After 12 weeks on a standard weekly dose, patients are divided into those showing some improvement and those whose condition is unchanged The former continue to receive the same weekly dose until they have been in remission for 1-2 weeks, and are then given a maintenance dose at longer intervals The unresponsive group proceed to a higher weekly dose, and to a second division at which the favourable reactors join the maintenance programme and the remainder move to a still higher dose Maintenance treatment is continued for an arbitrary period of 8 months When this method was used, 82% of patients had a remission, the corresponding figures for two types of standard course were 54% and 66% Smith et al hope that an even higher proportion of remissions will be achieved as refractory patients receive progressively more intensive treatment

Some years ago Lawrence[4] suggested a rather similar flexible dose scheme in which a fall in erythrocyte-sedimentation rate (or, better, in fibrinogen level) is used as a warning that the weekly dose of gold should be reduced This is consistent with the common observation that toxic reactions follow quickly on a good clinical response Lawrence held that the distribution of gold in the body was more important than its total concentration, believing that while the sedimentation-rate is high the skin and other potential sites for toxic effects are protected from high concentrations of gold by the readier diffusibility of the metal in areas of active inflammation and increased capillary permeability When the disease becomes less active this mechanism no longer operates and toxic reactions become more likely By adopting a flexible programme of dosage Lawrence reduced the incidence of stomatitis, and lesions of both mouth and skin became mild and transient rather than persistent and distressing disabilities Both Smith et al and Lawrence are prepared, in patients who have had toxic signs, to continue treatment with gold at a suitably adjusted dose level After mild toxic reactions had subsided Smith et al encountered subsequent undesirable reactions no more often than in patients treated with standard courses Severe toxic reactions often result from failure to interrupt treatment promptly when early signs develop

A flexible dosage programme may improve the results of treatment with gold, but it clearly calls for full appreciation of the principles involved, and for close supervision of patients and frequent measurements of sedimentation-rate Dermatitis and stomatitis, quickly detected, may by prompt adjustment of dosage be reduced to trivial complications, but more dangerous complications, such as thrombocytopenia, remind us that gold is a poison still to be handled with respect

CANCER AND SOIL

MEN have long speculated whether differences in cancer incidence might not be due in some way to the soil As long ago as 1868, Farr and Haviland[1] examined the death-rate from cancer in England and Wales in relation to the geological map and concluded that the disease was commoner in low-lying clay areas liable to seasonal flooding by rivers, while more elevated districts, especially those with underlying chalk and limestone, tended to have low death-rates Haviland published several papers on the "medical geography" of Britain, with particular reference to cancer, the last of which appeared in 1899[2] Several observations by others indicated that the nature of the soil (using the term in its widest sense) influenced cancer mortality For the most part, these studies took the form of noting villages or small towns with a higher cancer incidence than neighbouring areas Behla[3] in Germany and Noel[4] in France concluded that cancer incidence was increased by insufficient drainage of the subsoil Williams[5] noted that in his country practice in Anglesey cancer was much commoner in a village where the soil was "heavy" than in a neighbouring village with a sandy subsoil or a third village standing on limestone, although the inhabitants of all three were similar in diet, occupation, and habits He deduced that "people living in clayey or retentive soils are more prone to cancer than those who dwell on porous soils such as sand or limestone"

These and other early reports have two serious weaknesses usually it was *total* cancer mortality that was studied, and allowance was not made for differences in the age-structure of the populations compared The study of regional variations in cancer incidence was put on a proper basis by Stocks,[6] who investigated the age-standardised mortality in England and Wales of cancer of separate sites Great contrasts were revealed One of the most striking concerned the mountainous areas of Wales, which seemed to show a mortality from stomach cancer three times as great as that of the chalk areas of south-east England Following the example set by Stocks, regional variations in cancer mortality have been studied in the Netherlands, where Tromp and Diehl[7] found that municipalities situated on peaty soils had a significantly higher mortality from stomach cancer than districts where sandy soils or river-clays predominated In a study of the incidence of cancer in Anglesey, Davies and Wynne-Griffith[8] found that stomach cancer tended to arise more commonly on those soils which show great biological activity because of an equable distribution of moisture at all seasons These soils would tend to have a high content of organic matter Legon[9] has compared the loss of weight on ignition (which, in the absence of calcareous matter, may be taken as an index of organic content) of samples of top soil from areas in North Wales and the Welsh Marches He found that this characteristic varied directly with the mortality from gastric cancer

Investigations into the relationship of soil to cancer of the stomach have now been carried a stage further In the course of field research covering North Wales and parts of Cheshire, Stocks[10] arranged for soil samples to be obtained from the gardens of the last residence of persons recently deceased from cancer The investigation covered the intestinal cancers as well as cancer of the breast and of the lung In addition, similar soil samples were taken from the residences of persons who had died from causes other than cancer, in order to provide a control series Some 1200 "cancer" soils and about 400 control samples were obtained The region chosen is of particular interest because the unusually high mortality from stomach cancer in North-West Wales (already referred to) is somewhat anomalous In England and Wales as a whole the disease has a substantially higher mortality in urban than in rural areas Accordingly a lower-than-average mortality might be expected in North-West Wales From the pattern of blood-groups, also, less gastric cancer than usual might be expected in this area, because here the proportion of group-A people is lower than average Racial predisposition can be discounted, because persons of Welsh extraction living outside Wales are not unduly susceptible to the disease The evidence therefore points to some local factor as being responsible for the excess mortality

The soil analyses reported hitherto[11] have revealed two interesting associations—though at this stage these must be regarded as tentative Garden soils from houses where a person has died of stomach cancer after fifteen or more years' residence have higher median concentrations of zinc and chromium than soils of similar gardens elsewhere in the same area where a person has died of a cause other than cancer or of cancer after residence of less than two years Cobalt, iron, lead, titanium, and vanadium showed no statistical association with cancer, while nickel, the other trace element which was examined, showed a negative association No explanation can be offered, but zinc is an essential element in the molecule of carbonic anhydrase enzyme and also possibly of the insulin molecule, and some early work suggests that zinc may be concerned with the glycolytic processes of tumour cells But the zinc-cancer association, being evident in areas outside North Wales as well as in the high-cancer area, though it may eventually prove to be in some way related to the general level of incidence, cannot be held to account for the excess mortality in the region

The association described by Davies and Wynne-Griffith may, on the other hand, prove to be the local factor which accounts for the excess, because in North Wales, but not elsewhere, the organic content of soil was related to gastric cancer but not to other cancers Three indices of organic content were used, and all gave broadly similar results Cancer of the stomach occurs more commonly in relation to soils with a high organic content after residence of ten to nineteen years and with moderately high content after residence of twenty years or more

This work on soils is being pursued at the Department of Agricultural Chemistry of the University College of North Wales, where arrangements have been made to analyse a common garden vegetable grown on "cancer" and "non-cancer" soils

MIDDLE AGE IN NEW GUINEA

A CITIZEN of Great Britain, on reaching the age of 50, may find that since his student days his weight has gone up 15 lb, that his systolic and diastolic blood-pressures are now 25 and 10 mm Hg higher, and that the level of cholesterol in his serum has risen by 30 mg per 100 ml Such a man can certainly call himself normal and claim to represent the man-in-the-street, and, if he reads medical textbooks, he will have no difficulty in finding authorities who state that these rises are physiological—whatever that may mean

There have been several reports that such rises do not occur in some groups of men or women who lead a primitive life, for the most part unaffected by the Industrial Revolution Some of these are based on limited observations, but Whyte [1 2] has just completed a field study in which measurements were made on over 600 natives of New Guinea Good modern methods of measurement and of statistical analysis were used It was found that in both men and women in New Guinea systolic blood-pressure and serum-cholesterol are unchanged on reaching middle age, but that there is a fall in diastolic pressure of about 10 mm Hg and a fall in body-weight of about 10 lb

The natives of New Guinea are very small, the average height of the men being only 5 ft 1 in, but their weights were normal for their heights, judged by the Metropolitan Life Insurance Company standards They also appeared muscular and of good physique This suggests that genetical rather than dietary factors are mainly responsible for their small size The surveys were carried out in two districts—the highlands, where altitudes range from 5000 to 9000 feet, and on the coast In both the population is sparse and the small villages widely scattered Their diets contain little protein, the estimated intake being 30 g a day in the highlands and 40 g a day on the coast Both groups consume extremely little fat, and the highlanders also have little or no salt, which those on the plains do not lack The virtual absence of fat in the diet can probably explain the absence of a gain in weight and of a rise in serum-cholesterol as age advances There was no difference between the highlanders and those on the coast in blood-pressure levels, despite their different salt intake, and so this study lends no support to the claim that high blood-pressure is attributable to a high salt intake In New Guinea the people are certainly not exposed to the "stresses and strains" of modern civilisation Whyte does not discuss their manner of living, but life is seldom easy in a primitive society and no doubt they have their worries and their emotional disturbances

In Great Britain the increases in middle age of weight, blood-pressure, and serum-cholesterol, described above as normal, are certainly compatible with health and a long life But larger increases are also common, and these are certainly associated with degenerative diseases of the heart and arteries From these diseases the natives of New Guinea seem to be singularly free Price, who has done 600 necropsies, informed Whyte that in only 1 case was death attributable to coronary-artery disease, and he found that atheroma was generally absent or very slight Hypertension is virtually absent among these people As Whyte remarks, the inhabitants of New Guinea lack many things—protein, fat, gross obesity, and city bustle Probably for these reasons they seldom suffer from degenerative cardiovascular diseases, yet they also lack the comforts and amenities of civilised life and the skills and energy necessary to protect themselves against infectious diseases To acquire these advantages man may need a lot of protein, fat, and city bustle Perhaps we cannot have it both ways

PLEURAL BIOPSY

A DIAGNOSIS of tuberculous pleural effusion commits the patient to protracted chemotherapy and sets administrative wheels in motion, hence it is highly desirable to confirm this diagnosis But since, even with the best bacteriological technique, tubercle bacilli can be grown from the pleural fluid in only some cases, pleural biopsy has been used to obtain additional information, [1–10] and Hill et al [11] and Weiss [12] now report on the value of this increasingly popular procedure

In 23 cases of presumptive tuberculous pleural effusion without demonstrable pulmonary disease, Hill et al cultured tubercle bacilli from the fluid in only 4 cases, whereas investigation of biopsy material led to a diagnosis in 15 cases In 5 of these 15 cases the diagnosis was based on the histological appearances alone, in 9 histological evidence was confirmed by culture of the tubercle bacillus, and in 1 the diagnosis was made on culture results alone In a further 9 cases, in which there was pulmonary as well as pleural disease, biopsy was of no help, the diagnosis was established by other means in 7 cases, and pleural biopsy was merely confirmatory in 4 of these

Weiss carried out pleural biopsy in 31 cases of presumptive tuberculous pleural effusion with or without pulmonary involvement, and made a histological diagnosis of tuberculosis in 23 Pleural fluid was cultured in 27 of the 31 cases and was positive in 16 instances, and the combined results of pleural biopsy and culture of the fluid gave positive findings in 27 of the 31 cases Hill et al warn that the finding of a non-specific pattern of pleural inflammation does not exclude tuberculosis, and these workers and Weiss agree that, although pleural biopsy may occasionally demonstrate a malignant pleural condition, the procedure is of value chiefly in establishing the presence of tuberculosis, as in this condition the pleura is usually very extensively involved

Pleural biopsy may be carried out as an open operation under general or local anæsthesia, or blindly using a special needle such as a Vim-Silverman Despite the necessity for a surgeon and an operating-theatre, Hill et al prefer open operation under local anæsthesia to needle biopsy, because a suitable piece of pleura can be selected and enough removed to permit bacteriological as well as histological examination Weiss, on the other hand, maintains that if thoracentesis is performed needle biopsy may as well be done at the same time and open operation kept in reserve—a reasonable opinion in view of his high proportion of successes with the simpler method

Occasional Survey

EXERCISE-TOLERANCE TESTS

E. A. Harris
M.B. Lpool, Ph.D. Edin., M.R.C.P.

Impairment of the capacity for physical exertion is a common symptom of disease. In cardiopulmonary disease it is by the severity of this symptom and its rate of progression or regression that the necessity for treatment, the type of treatment, and the response to treatment are largely judged. Assessment of the degree of impairment at any given time is usually made on the basis of the clinical history, but, valuable though the latter may be, it can never be objective, since it is influenced by the motives, personality, and intelligence of both patient and physician. The lack of objectivity is particularly regrettable when decisions for or against surgical measures such as mitral valvotomy are in the balance. In many such cases help can be obtained from cardiac catheterisation, but this is a routine procedure in only a few centres, and in any case it cannot be said to assess the patient's capacity for any ordinary activity. A reliable, simple, repeatable, and safe "exercise-tolerance test" would therefore be very useful. Despite the attention given to this question by many investigators the ideal test has not yet been realised.

Clinical exercise-tolerance tests are closely related to tests of fitness for athletic, industrial, and military purposes. In this article existing tests in all these fields are briefly surveyed. The emphasis throughout is upon tests which are relatively simply performed and therefore technically suitable for routine application. The tests so far proposed fall into three groups: (1) those based on ventilatory measurements; (2) those based on records of heart-rate; (3) those involving measurements of maximum oxygen consumption or oxygen debt.

VENTILATORY MEASUREMENTS

The Ventilatory Equivalent

When the ventilation-rate increases abnormally on exercise, as in many types of cardiac and pulmonary disease, the ratio of ventilation to oxygen uptake or to carbon-dioxide output is abnormally high. These fractions were termed the "ventilatory equivalents" (V.E.) for oxygen[1 2] and for carbon-dioxide.[3] They were originally regarded[4 5] as reflecting alterations in pulmonary blood-flow, and this view found a measure of acceptance.[6] However, the V.E. may be increased by nervous hyperventilation, by excessive ventilation of the dead space due to rapid shallow breathing,[7] and by the respiratory stimulus of metabolic acidosis, as in the lactic-acidæmia of exercise. Donald et al.,[8] for example, found no consistent relation between V.E. and pulmonary blood-flow during exercise in patients with mitral stenosis. The V.E. can be regarded as a rough index of ventilatory efficiency, but in the absence of other data it cannot be interpreted precisely.

The Respiratory Frequency

Wahlund[9] used the respiratory frequency as an index of working capacity, which he defined in this connection as the rate of work at which the frequency reaches 30 breaths per minute. This value was arbitrarily chosen as the limit of efficient respiration. Respiratory frequency is, however, a very variable function; it can be regulated consciously by the subject and is apt to be influenced by breathing apparatus in subjects unaccustomed to wearing it. Matthews[10] found the respiratory frequency to be useless as an index of exercise ability in patients with mitral stenosis.

The Hugh-Jones Test

Hugh-Jones[11] found that the ventilatory "debt" after 5 minutes' standard exercise was equal to the ventilatory "deficit" of early exercise in healthy people and in patients with emphysema who could finish the exercise. In patients who were unable to complete 5 minutes' exercise the debt exceeded the deficit and the difference was roughly proportional to disability. Stock and Kennedy[12] obtained similar results in mitral stenosis. In exercise below the healthy or emphysematous subject's aerobic capacity the debt never materially exceeds the deficit[13] and the exercise must be severe (for the particular subject) before the test begins to be "positive". It is thus a maximal test and as such may be undesirable in some conditions, though doubtless safe in emphysema. Its interpretation is also subject to the uncertainties surrounding the ventilation equivalent.

Comments

The current view of dyspnœa[14] is that it arises whenever ventilatory demand approaches the available ventilatory capacity. By measuring both of these, it should theoretically be possible to "measure" dyspnœa. The Hugh-Jones test depends partly upon ventilatory demand and supply during exercise. However, the observed ventilation during an exercise test may not be the true ventilatory demand for that rate of work, because the subject's unfamiliarity with the conditions of the test may induce unnatural breathing—usually hyperventilation but occasionally the opposite. Further, the potential candidate for industrial compensation may have a powerful motive for making himself appear as disabled as possible. Measurements of maximum ventilatory capacity too are subject to the patient's voluntary control; the resting value, moreover, does not necessarily apply to exercise. For these reasons ventilatory measurements have serious limitations when used alone as indices of performance.

HEART-RATE

The Recovery Heart-rate

(*a*) *Master's step test*[15 16] depends entirely on a single pulse-count taken sitting 2 minutes after standard exercise. Master asserted that the test would distinguish differences in disability which were otherwise undetectable. The grounds for this assertion are not clear.

(*b*) *The Harvard step test*[17] has been widely used in the athletic field and a more severe form of it (the "pack test") for military purposes. Since the recovery heart-rate curve is approximately exponential, it can be characterised if three points on it are known. The Harvard test utilises pulse-counts at 1–1½, 2–2½, and 4–4½ minutes of recovery, and these are incorporated into an index of fitness.

Master's test has not been critically re-evaluated, but criticisms of the Harvard test should apply more forcefully to Master's Cureton et al [18] compared the Harvard step test with the ability to perform a variety of gymnastic and athletic feats Their very thorough study showed a strikingly low correlation Taylor [19] concluded that the recovery heart-rate curve is not closely related to the capacity for exercise "It seems clear", he writes, "that one must look to the responses *during* exercise for critical measures of fitness for hard work" In the clinical field, Baldwin et al [20] found that in pulmonary disease there was no relation between pulse-counts, taken during recovery from exercise, and disability The causes of the raised pulse-rate after exercise are poorly understood and are probably related as much to peripheral vascular conditions, muscle tone, and posture as to cardiopulmonary status

The Heart-rate during Exercise

The measurement of heart-rate during exercise is technically more difficult than its measurement in the recovery period, but recent developments in instrumentation [21 22] have solved most of the technical problems Three tests have been proposed which make use of the heart-rate during exercise

(*a*) *Wahlund's test* [9]—The heart-rate, during the 3rd to 6th minutes of each of a number of exercises of different intensities, is counted and the heart-rate is plotted against the rate of work The rate of work corresponding to a heart-rate of 170 beats per min is taken as the "working capacity" To avoid error from extrapolation the exercise must be pushed to somewhere near the "working capacity", and this is therefore a *near-maximal* test Wahlund showed clear differences between dissimilar groups of healthy subjects and patients, but the value of the test in the individual subject is hard to assess from Wahlund's data

(*b*) *Astrand and Ryhming*,[23] having found that the heart-rate in the steady state of submaximal exercise could be correlated with the maximum attainable oxygen uptake ("aerobic capacity"), constructed a nomogram from which the aerobic capacity can be read if the work-rate (or oxygen uptake) and heart-rate are determined for a single submaximal exercise These workers suggested a clinical application for the test because it is a submaximal one There appears to be only a fair correlation between determined submaximal heart-rate and determined aerobic capacity, and there is much individual scatter in the published figures

(*c*) *Müller* [24] proposed what he termed the "*Leistungspulsindex*" (L P I), which consists essentially of the rate of rise of heart-rate with increasing rate of work The absolute heart-rate reached at any exercise level is not taken into account in calculating the L P I Muller showed fairly good correlation between L P I and an estimate of maximum performance and also demonstrated improvement in the index during a training programme in two subjects

It has been known for many years that "fit" subjects tend to have lower heart-rates than "unfit" subjects at the same rate of work, and also that patients with cardiac, pulmonary, and other disease respond to effort with a greater tachycardia than healthy people The factors responsible for the tachycardia of exercise are, however, poorly defined and are therefore difficult to control experimentally Consequently random fluctuations in these factors, while mutually compensatory when groups of subjects are compared, make individual comparisons unpredictable There is probably more chance of error from this source when the absolute heart-rate is the criterion, as in the Wahlund and Astrand-Ryhming tests, than when Muller's L P I is used For example, an athlete showed day-to-day variations in the first two of these tests of up to 20%, whereas his L P I remained almost constant [13]

All these tests utilising heart-rate during exercise have been introduced during the last 10 years and none has yet been critically reinvestigated *Muller's test appears*, a priori, to have advantages over the other two, but has never been assessed clinically Perhaps the heart-rate tests may yet be put on a more rational basis as more is discovered about the mechanisms of the tachycardia of exercise The findings of Harris and Porter,[25] for instance, indicate that the "heart-beat deficit" of early exercise might be developed as a possible index of performance, since it appears to parallel the oxygen debt At present, however, no exercise-tolerance test based on heart-rate can be confidently recommended for clinical use

MAXIMUM OXYGEN UPTAKE AND OXYGEN DEBT

Maximum Oxygen Uptake

This is the ultimate measure of the capacity of the oxygen transport and utilisation systems, and has been so recognised since the classical work of A V Hill and his school The maximum oxygen uptake is different for different types of exercise and is also increased by preliminary "warming up" [26 27] Taylor et al [27] have proposed it as an index of cardiorespiratory performance, and for healthy subjects it is probably the best index available Maximum oxygen uptake in exercise involving a large muscle mass is mainly limited, in health, by the maximum cardiac output [28] Since the measurement of maximum oxygen uptake involves maximum effort it is unsuitable for clinical purposes

Oxygen Debt

Margaria et al [29] found that the oxygen debt after standard treadmill exercise increased in rectilinear fashion with increasing exercise up to an oxygen uptake of about 2000 ml per min in a healthy subject At rates of work above this intensity the debt curve rose more and more steeply, becoming almost vertical at the limit of tolerance The end of the linear phase corresponded to the exercise intensity above which lactate began to accumulate substantially in the circulating blood In exercise at the same submaximal level the blood-lactate,[30] and the oxygen debt after exercise, are greater in the unfit subject The same was shown to apply in disease of the heart and lungs by Katz et al [31] and Nylin [32 33] These workers devised clinical exercise-tolerance tests based on this finding

Since significant differences in oxygen debt between

subjects may be found at exercise intensities well below maximum levels, tests based on debt measurements are suitable for clinical use. Moreover, it would seem almost impossible for a subject voluntarily to influence his oxygen debt, and this consequently provides a truly objective measure of performance Of all existing tests, this is the one which, from the clinical point of view, would probably most repay further study and development.

COMBINED TESTS

Composite indices have been proposed from time to time. Bruce et al [34] developed a "physical fitness index" (P F I) combining recovery heart-rate with ventilation equivalent While they thought this index helpful in the assessment of cardiac patients for operation,[35] it seems doubtful whether the P F I is fundamentally more reliable than its individual components

DISCUSSION

The term "exercise tolerance" is often used in clinical discussions, but few attempts have ever been made to define it. Wahlund [9] used it to mean the highest exercise intensity which the subject could maintain efficiently in a steady state But how do we recognise efficiency or inefficiency? The physiological responses to exercise, for the most part, follow a continuous gradation from the mildest exercise to the most severe, and at no point is it easy to say that exercise has become "inefficient" Wahlund was, as we have seen, obliged to use quite arbitrary levels of heart-rate and respiratory frequency as his criteria Alternatively we might, with Cureton et al.[18] and Taylor,[19] regard the subject's maximum performance as the only reliable criterion of his "exercise tolerance" In clinical work this definition is unhelpful (1) because of the risk involved in maximal exercise (one patient, at least, with mitral-valve disease, has died after exercise on a treadmill [34]), and (2) because one can never be sure of a patient's full cooperation and maximum effort A submaximal test is needed, but submaximal tests based on measurements other than oxygen debt have the disadvantage that there is no standard against which to assess them in clinical work—except for the history (and if this were reliable and quantitative there would be no need for an objective test) On the other hand an assessment based on oxygen debt has a physiological validity which requires no comparison with other and possibly spurious criteria The oxygen debt, indeed, is almost the only indication we have that the exercise which preceded it was "inefficient"

The oxygen debt depends upon the adequacy of the oxygen supply to the working muscles during exercise, and is thus influenced by the oxygenation of blood in the lungs, the oxygen-carrying capacity of the blood, the cardiac output, and the state of the arteries supplying the muscles These cover most of the causes of impaired working capacity It is nevertheless conceivable that a person with, for instance, mitral stenosis or hypertensive heart-disease may be forced to stop exercise owing to dyspnœa from pulmonary engorgement while the oxygen supply to his working muscles is still sufficient to avoid a lactacid oxygen debt If this is so, a test based upon oxygen debt might fail to reveal his true disability The limitation of exercise tolerance due to angina of effort also falls into a special category

From this brief survey it is clear that no clinical test of exercise tolerance has yet been developed to the point of practical usefulness In clinical tests a compromise usually has to be found between reliability and technical simplicity. The latter must, however, be evaluated in the context of current trends, and in view of the increasing refinement, complexity, and costliness of modern methods of diagnosis and treatment it would be unrealistic not to accept a reasonable degree of technical difficulty provided the test were reliable

The time has come to take stock of the advances in our knowledge of exercise physiology and pathophysiology and to see whether a reliable exercise-tolerance test can be devised The problems to be faced are, in detail, numerous, but the main lines on which further work might most profitably proceed are fairly clear Firstly, a good deal remains to be learnt about the precise conditions under which an oxygen debt is contracted and repaid in health and disease Secondly, a better understanding of the mechanisms whereby the heart-rate increases during exercise would remove much of the empiricism which surrounds existing tests based on heart-rate, and might point the way to a rational and reliable use of cardiotachometry for the assessment of exercise capacity

Meanwhile, can anything be done to supplement the patient's own account of his disability? The practice of walking upstairs or round the hospital grounds with the patient (or sending the house-physician with him!), besides requiring no apparatus and helping to keep the doctor fit, is often surprisingly informative It is not uncommon for the patient to score quite heavily in such a competition, and one then has little doubt that his exercise tolerance is reasonably good. The opposite result, in which the patient fares badly, must of course be interpreted with due caution.

SUMMARY

Existing tests of capacity for exercise are reviewed and their merits considered So far as the clinical assessment of exercise tolerance is concerned there is at present no suitable test of proven reliability The measurement of oxygen debt after standard exercise appears to be the most promising basis for such a test, but it probably cannot supersede measurements of pulmonary ventilation and heart-rate While the interpretation and limitations of ventilatory data are now well appreciated, more needs to be learnt about the tachycardia of exercise before tests depending on measurements of heart-rate can be put on a rational basis

Medicine and the Law

A Danger on the Roads

A Chester court was told on Aug 8 that heavy smoking may cause a driver to confuse the colour of traffic signals [1]

The defendant, who had driven across a road when the traffic lights were against him, and collided with a cyclist, told the police that he believed the signal was green and in his favour Through his solicitor he said he would not drive again until a specialist—who had diagnosed the condition of "smoker's eye —said he was cured.

Tobacco amblyopia, as a clinical manifestation of vitamin B_{12} deficiency, was discussed in our issue of Aug 9 [2]

Special Articles

STARTING A SCHIZOPHRENIC UNIT

Elisabeth Shoenberg
M A Cantab, M R C S, D P M
SENIOR REGISTRAR, ST BARTHOLOMEW'S HOSPITAL, LONDON, E C 1, AND GOODMAYES HOSPITAL, ILFORD, ESSEX

Roger Morgan
M B Lond, D P M
REGISTRAR, GOODMAYES HOSPITAL

In June, 1957, we opened a schizophrenic unit for men up to about 35 years of age In it were gathered together 24 long-stay patients who had been scattered through the various chronic wards, together with 6 acutely ill schizophrenics under insulin treatment from the admission ward Our purpose was to de-institutionalise the long-stay patient, to prevent the acutely ill from becoming " chronics ", and to help both to fit themselves for return to the community wherever possible For those whose discharge did not ultimately prove practicable we hoped to make life happier and to prevent further withdrawal Our aims were (1) to reproduce real-life pressures by being no more, and little less, permissive than real life itself, (2) to bring the families into the treatment situation, and (3) to have maximum communication between patients, staff, and relatives

Social training of the chronic mental patient tends to veer between rigid habit-training and unlimited permissiveness Since our objective is always reintegration into the outside community, at however humble a level, we have taken pains to avoid both extremes Rigid habit-training leads to disappointingly little useful conditioning for independent activity, and unlimited permissiveness seems to require greater ego strength than the average schizophrenic possesses We have tried to be no more permissive than real life itself, but we also give as much opportunity for free choice and decision-taking as is possible This means that we do not leave the decision about working to the patient, any more than it is left to the ordinary person For nearly every adult male, going to work regularly is one of the unavoidable pressures of daily life, and this pressure is introduced into our unit to help the schizophrenic prepare himself for leaving the hospital Leisure, on the other hand, is relatively unorganised in normal life

In the average chronic ward, the position is the reverse of the real-life situation Entertainments are often laid on fairly lavishly and can be hard to evade, but work (though encouraged) is optional In our unit work is the one really compulsory thing No entertainments are available other than those organised by the patients, and, within very wide limits, the patients run the ward democratically

We lay great stress on the work always being on a community project of a finite nature, with something completed and concrete as an end-product, so that the patients can take pride in seeing a job completed, and can learn to work together as members of a team This develops group feeling and makes it possible to involve the very withdrawn in social and productive activity, since even the little they do is done in association with others (who tend to spur them on) and is a positive contribution

A vital step in returning the schizophrenic to the community is to help his family to accept him and to understand him, this means making a complete assessment of his social background and involving his relatives in the treatment We therefore have very full communication with the relatives, both individually and collectively, invite them to join in ward activities, and encourage them to have the patients home for weekends and holidays The families of many chronic schizophrenics often have very severe emotional difficulties and may either reject the patient outright or smother him with ambivalent solicitude, and helping them may have a decisive effect on the patient's recovery

We have full discussion with the patients at weekly ward meetings as well as individually, so that wherever possible they plan their own lives and understand the purpose and method of treatment The nurses and doctors meet weekly for full and frank discussion of plans, activities, and problems The psychologist, psychiatric social workers, and occupational therapists are invited to attend these meetings

Preliminary Planning

Our first tasks were to select the patients, find a ward for them, staff it, find suitable jobs for the work projects, and get adequate psychological and social information

We fixed an arbitrary upper age-limit of 35, and all the chronic patients of this age or under were interviewed by one of us All the departments were visited as possible sources of work, and the problem of finding a finite constructive job on which 20–30 men could work together was discussed with the head occupational therapist, administrators, engineers, gardeners, and indeed everybody we met

Full social and psychological assessment was planned with the psychiatric social workers and the clinical psychologist

Finally, the staffing was planned at a meeting of the physician superintendent with all concerned Despite the shortage it was considered vital to have a full complement of nurses, who should change as little as possible, to ensure continuity They originally consisted of a charge nurse, two staff nurses, and a student nurse on each of the two shifts Eventually, however, we had to give up the second staff nurse and have instead a nurse on duty from 7 A M to 5 P M

The ward selected was in the main hospital, so to go there was an apparently retrograde step for patients comfortably and " permanently " settled in modern " chronic " villas surrounded by pleasant gardens

24 long-stay patients were chosen, the criterion being a certain minimum capacity for communication, comprehension, and cooperation The standards were set deliberately low so that hallucinations, delusions, and a considerable degree of withdrawal did not disqualify The habitually disturbed, the incontinent, and the lost were, however, excluded 16 were voluntary and 8 certified The average number of admissions was 3 2, and the number of years since first admission varied from 1 to 16, the average being 6 5 21 patients had had insulin-shock therapy at some time, 18 electroconvulsion therapy, and 4 standard leucotomies Before transfer to the new unit 14 did some sort of hospital utility work, 5 did regular occupational therapy, and 5 were quite unoccupied

The insulin unit was transferred from the admission ward to the new ward, with the 6 patients receiving insulin

Opening the Unit

A few days before the unit was due to open, relatives of the selected chronic patients were invited to a meeting 47 relatives of 23 (of the basic 24) patients came At the meeting it was explained that we were opening a new ward for the social rehabilitation of young men Schizophrenia was not actually mentioned, but its effects in causing deterioration were discussed, as well as the effects of institution life, and a very cautious statement was made of plans and hopes The relatives were asked for their cooperation, especially over taking the patients home at weekends and at other times

The meeting was very lively and interested, and people repeatedly said how pleased they were to meet others with the same problems and to discuss mental illness without shame. They were extremely anxious to cooperate with the hospital, asked innumerable questions, and said they would like to meet regularly "to help our boys." They were pathetically grateful to us for consulting them, and constantly repeated that they wanted to work *with* us. Several offered to invite boys home who had nowhere to go, and there was much discussion (entirely spontaneous) about how they could help in finding work not only for their own relative but for his friends in the unit. It was agreed to meet again in two months.

The day before the ward actually opened, the 24 chronic patients were brought to a meeting, where it was explained to them that they were to be transferred to a new ward.

They showed little interest at first, sitting with bowed shoulders and apathetic rather blank faces. Most stared vaguely at their laps or turned their eyes up to the cornice with moving lips. They did not seem to listen or take much notice of each other, and looked a depressingly shambling stooping deteriorated set of typical long-stay mental hospital patients. The first response came when they were asked to take a good look at each other and say what they had in common. 6 immediately looked up, and very slowly the others gradually raised their heads and looked around in slow motion. Finally somebody said "We're all young", and several others agreed. From that moment they seemed to listen. It was explained very simply that it was hard on young men to be scattered in wards with elderly men who were not very active, and that we hoped to give them a fuller and more interesting life by concentrating the young men together, and that we wanted to help them regain their confidence and working capacity so as to fit them to leave hospital.

On the whole, the reaction was one of considerable anxiety—partly at having to make any change in their familiar routine, and partly at what the change might really mean. The better patients resented leaving snug, privileged positions and being grouped with the others, the more deteriorated showed a sort of primitive irritability at being poked. They acquiesced in a dreary resigned way to being moved but they did not care for the idea.

The unit started on its activities at a deliberately very slow tempo. We gave them a three-week settling-in period so that the mere fact of being together in a new ward should be all they had to contend with at first. During this time they continued at whatever they had been doing before transfer, working individually in various departments, attending occupational therapy, and so forth. The only change made in their routine was that, from the beginning, they had to make their own beds and join in doing all the ward chores, instead of leaving these to a few ward workers. No ward entertainments of any kind were provided. During this period the patients attended the clinical psychologist for individual assessment.

A weekly ward meeting of patients and staff, with one of the doctors acting as chairman, was initiated. By the second week the patients were growing restive and complained that life was dull and that nothing was done to entertain them. They were then invited to elect a committee of five, and it was at this point that they began to show the first signs of independent action and community feeling. They insisted that all 9 of the candidates nominated should form the committee. They declined our suggestion that a nurse on the committee might be helpful. When asked what they considered the committee's function to be, they surprised us by saying it was to organise work. We fell in with this assumption, and they immediately went into session. They refused to come out for meals, and more than three hours later emerged with a detailed rota for doing all the ward domestic work. This was a far better and wider scheme than anything the staff had envisaged. A striking feature was that it had been planned so that the more deteriorated patients were always put on duty with more capable ones.

During this first period patients kept complaining to nurses and doctors that there were no activities laid on. They were always given the answer that it was up to them to organise whatever they wanted through their committee, and that the staff would be glad to help. In this way, considerable social pressure arose, the pronoun "we" began to be used more often, and an astonishingly wide variety of activities developed.

At the end of three weeks the complete ward routine was introduced, following preliminary discussions with both patients and staff.

All ward domestic work is finished in time for the patients to put on working-clothes and to be out at work by 10 A.M. They knock off in time to get back to the ward and wash, ready for lunch at 1 P.M. In the afternoons there are various communal pursuits—e.g., play-reading, swimming, physical training, football, and cricket. Selected patients meet for group therapy once or twice a week. Thursday is a free afternoon. In the early evenings there are occupational-therapy hobby classes twice a week, and in the evenings a great variety of social events. Patients are encouraged to go out as much as possible and to go home at weekends. The insulin patients have their treatment during the morning but are drawn into general ward activities during the rest of the day. The staff meet weekly to discuss ward affairs, blow off steam, and settle policy. Frank criticism is encouraged, and this has done much to ensure smooth working together.

Work and Leisure

Our first project was to make a drive and gardens for the new occupational-therapy department.

The ground was extremely rough and full of iron and concrete posts, a concrete sunken shelter, a jungle of weeds, builders' debris, and a sort of artificial mountain resulting from the builders' excavations. The men worked hard and consistently, asked to see the architect's plans, and frequently discussed the job at ward meetings, making all sort of criticisms and suggestions. Even the most apathetic and withdrawn gradually began to do a little, though they needed a lot of encouragement. The nurses voluntarily worked with them, putting on denims and heavy boots, which is not the tradition in this hospital, and tactfully drawing into activity the apathetic preoccupied patients who tended to lean on a spade, listening to hallucinatory voices.

Our second project was the construction of a hospital car-park. We also undertook the destruction of some air-raid shelters, and the uprooting of a lot of fences no longer needed in a hospital with unlocked wards. The third project was a hospital road-widening scheme.

The response to all this hard navvying work was unexpectedly enthusiastic, the men seem to like purposeful physical activity and to enjoy both the destructive and constructive aspects of the work. They take a keen interest in the project as a whole and discuss it very critically. We have tried to foster this critical attitude by showing them the working drawings and by talking over the various difficulties as fully as possible at ward meetings. They take great pride in the finished job and are often to be seen showing their visitors what has been accomplished.

It was very interesting to see their reaction to being put on non-project work for a few days. Between projects the patients were asked to lend a hand, as individuals, in routine gardening. This work is productive and useful, but they all grumbled and obviously felt bored and discouraged Several explained that they wanted a job of their own, where they could work together and see what they had accomplished Patients are paid 5*s* 6*d* a week for their work (the rate in this hospital for ward and garden workers) There are occasional grumbles, and many jokes about chain gangs and the Burma Road, but most seem to realise that work is primarily treatment and only secondarily money-making Patients on insulin treatment are paid 2*s* a week

The patients take their duties of self-government very seriously and have made life so busy for themselves that sometimes they have difficulty in sparing time to be interviewed by their doctor At the weekly ward meeting the ward secretary reads the minutes, the treasurer gives his report, and the doings of the week are discussed and new plans considered When new activities are suggested, as they constantly are, there is usually quite lively discussion, and sometimes a vote is taken If something new is decided on, a patient usually volunteers to make arrangements and reports back the next week

The ward meetings follow a fairly set pattern We try to promote discussion and argument, while saying as little as possible ourselves We react less strongly to the occasional deluded ramblings than do the patients themselves, who become very restless and practically eliminate any contribution that is not strictly to the point We wait quietly through periods of silence but are not slow to close a meeting after 30–45 minutes when it is clear that nobody has anything more to say

Making money for the ward funds is a constant preoccupation Within two months the fund was up to £14 Money has been made by a tea-club which sells extra refreshments, raffles, a white-elephant stall at parties, and selling things made at the occupational-therapy hobby class The money is spent on theatres, football matches, and so forth, and there are also share-outs when patients go on leave at the end of a project

A parallel unit for schizophrenic women was opened about a month after the male one, and there is a great deal of joint activity This free mixing of the two wards grew up spontaneously The first move was made by the men, who wanted dancing-lessons, and on their own initiative invited the girls over for the first lesson This grew into a weekly informal dance Next the men invaded the women's cookery classes, the women came over to join the play readings (which are very dramatic affairs run by a professional coach), and soon the two wards had formed a habit of mixing socially on most days This was unpopular with quite a number of the men, who felt shy and nervous with women, but they have gradually come to tolerate their visitors and have even made friends

There are all the normal activities and games (table tennis, snooker, billiards, darts, football, cricket, and baseball), with whist drives, regular visits to the local swimming-baths, hobby classes, and cookery lessons (by the hospital catering officer) There are two or three socials a week, and our patients take a prominent part in hospital social life as a whole They are the most active members of the hospital social club and organised the hospital Guy Fawkes party they built the bonfire, set off the fireworks, and fed the company on roast potatoes There are also a skiffle group and a fortnightly ward newspaper In the summer the patients arrange a weekly outing, for which they are allowed to use the hospital coach, and it is left entirely to them to plan the outing and to finance it if necessary Most of the outings have been to Southend and other local places during the summer, but the patients have also been to Kew Gardens, Hampton Court, a circus, the Zoo, the Science Museum, and Wembley (to watch England *v* France), and have on several occasions made block bookings at theatres One play chosen was *Look Back in Anger*

Regular end-of-project parties are held These are organised entirely by the patients, who send out formal invitations to their relatives and friends The first of these ward parties, about five weeks after the ward opened, arose out of the promise at the first relatives' meeting to meet again in two months' time The party was a remarkable success, gave an excellent opportunity for staff and relatives to meet and talk, and showed the patients in a new light to their relatives, most of them acting very competently as hosts Further parties were clearly indicated, and it occurred to us to hold them at the end of each work project, with a week's leave after each

The projects are planned to last about three months Their completion is accompanied by a general feeling of pride and satisfaction, and it is fitting to mark this by a kind of end-of-term celebration The leave period is useful in several ways Mild pressure can be brought to bear on relatives who seem unreasonably reluctant to have patients home It is a convenient landmark at which to discharge the occasional patient, this is mainly useful with short-stay patients and can be a lever to dislodge some or to hold others for those few weeks longer which may be desirable Above all it breaks up the dreary interminable succession of months which in an institution follow one another without interlude or highlight We hope it may have some effect in restoring a form of rhythm to patients' lives and possibly combat the time distortion of the chronic schizophrenic Usually more than half the ward go on leave at this time, thus giving the staff a brief opportunity to concentrate on the more deteriorated patients who are left these enjoy a week in which they get all the attention

When insulin patients first join the unit, the long-stay patients are extraordinarily tolerant of the extravagances of the acutely ill, draw them into ward activities, watch over them for signs of secondary coma, and give them constant encouragement As the insulin patients improve, they in their turn contribute to the community They take a leading part in organising activities and bring their outside interests into what might otherwise be a too self contained little group Insulin treatment is followed and accompanied by social training, and valuable continuity is achieved with none of the trauma that so often accompanies a patient's transfer from the insulin unit to a convalescent ward

Putting the insulin unit into this open ward, which lacks the staff necessary for 24-hour continuous observation of patients in bed, gives rise to certain difficulties Some acutely disturbed recent admissions have been too unreliable for such a ward and have had to be treated elsewhere until electroconvulsive therapy, chlorpromazine, or the healing power of Nature has made them socially suitable for insulin-shock therapy Others, who continued too disturbed for the ward, have had to be denied insulin-shock therapy even when it was considered the treatment of election

New entrants to the unit, whether for insulin or for social therapy alone, have come through other wards They are always vetted by one of us, and there is no direct admission

The influence of other patients in social therapy is proving very valuable

A good example of this is the Junior Supper Club About 12 of the better preserved patients meet informally in the kitchen most nights for a little supper which they buy and cook for themselves on a communal basis This has been nicknamed the Senior Supper Club One member organised what he calls the Junior Supper Club For this he gathered together the 8 or 9 most deteriorated patients—the withdrawn apathetic ones who join in very little and would certainly not agree to pool their money for supper He draws them together each evening, makes them toast and hot milk, and often provides more at his own expense After months of persistent effort the Junior Supper Club now assembles fairly spontaneously, and some of its members now help to make the toast, wash up, and begin to show a very little social feeling

Staff and Patients

The great stress laid on maximum communication between patients, nurses, relatives, and doctors makes it possible to foster and recognise—as well as tolerate—the first stirrings of initiative Great skill and patience are needed on the part of the nurses to guide the reviving patient into socially acceptable modes of expression This means that the ward offers an exceptionally good training-ground for the student nurses who come to us for up to three months at a time Their curiosity and receptivity are very valuable to the unit, and we ask them to make a careful study of particular patients They then present their observations to the ward staff meeting, and in this way patients are reassessed, and plans for treatment are made by the meeting as a whole This means that the long-stay patients with great folders full of forgotten notes are considered again as though they were new problems, and this often produces a new approach which is helpful to the patient

Of the 24 founder members, 5 have had to be transferred to other wards, 2 because they ran away repeatedly, 1 became intolerably aggressive, 1 impulsive, and 1 negativistic enough to be a bad influence 2 others did not return from leave and had to be left at home with our blessing if not our approval

There is a steady flow of discharges of short-stay patients, and the first 3 long-stay patients have now started work at a nearby factory, while continuing to live in the unit for the time being A 4th (the organiser of the Junior Supper Club) has just joined an Anglican monastery as a resident lay worker

This partial withdrawal of 4 of the best-preserved and most active long-stay patients has stimulated initiative in some of those who were content to be organised by them New leaders, though of rather inferior calibre, have begun to appear and take their work as committee members very seriously 3 or 4 patients show no improvement, do not cooperate, and try to avoid their share of communal chores They are much resented by the others and are often publicly criticised, but so far the community continues to tolerate them

Discussion

Living in a self-governing community and working as a group on socially useful projects has had a marked effect on the patients, which is commented on spontaneously by all who know them, especially their relatives "Even the goldfish are more active in this ward" is our most precious testimonial The patients themselves say that life is much more enjoyable now, and many comment on feeling fitter and more confident They look smarter and brisker, talk more spontaneously, and are altogether more responsive With a high proportion of those who have been severely damaged by their illness, this may well be all that can be achieved We hope, however, to return the others to the community

It is difficult to quantify the improvements observed or to assign cause and effect accurately, but there seems to be little doubt that we have established not only a happy ward but also one with therapeutic powers These therapeutic powers seem to depend to a very considerable extent on having the same nurses on the unit long enough to establish a real relationship, and on having enough of them Sometimes, when the hospital has been short of staff, we have had frequent changes, with nurses coming for short periods as reliefs These times have been marked by a sagging ward morale with a tendency to return to aimless drifting, and a failure to cultivate the patients' initiative A nurse doing this kind of work needs the same sort of patience as a mother who lets her 3-year-old do up his own buttons

Many of the chronic patients who have improved so much in bearing, work, and apparent social adjustment, retain intact their delusions and disordered modes of thought The King of the Incas, while retaining his imperial status, now works quite well, joins in the discussion, and looks neat and relatively brisk, compared with his former slouching idleness only relieved by occasionally toying with a little basket-work This suggests that much of the typical "chronic patient" appearance and behaviour is due to hospital conditioning, and is not necessarily an inescapable consequence of the primary illness The long-stay mental-hospital patient is all too likely to lose his human dignity through giving up his own responsibility for himself, and in our unit we are trying to prevent this happening

Summary

Our experience in starting a new schizophrenic unit on community lines is described We have tried to improve certain aspects of the care of long-stay patients in a hospital where (if we may say this, being only short-stay doctors) the standard of such care is already high The essential principles involved are (1) an attempt to reproduce normal stresses by introducing compulsory work and democratic social organisation, (2) bringing the families into the treatment situation, (3) maximum communication, (4) selective mixing of acute and chronic cases for mutual benefit

The preliminary planning and the mechanism of opening the ward are described, followed by a general account of how things have worked out during the first year

We are indebted to Dr G Somerville, physician superintendent, and Dr J E McA Glancy, consultant psychiatrist, for their help and encouragement as well as to Miss J Stapleton, clinical psychologist, Miss Abley and Miss S MacNulty, psychiatric social workers, and Miss M D Beldam, head occupational therapist, for their valuable assistance

THE HEALTH SERVICE IN 1957

LAST year, perhaps the most important event bearing on the National Health Service was the publication of the report of the Royal Commission on the Law relating to Mental Illness and Mental Deficiency [1] One of the Commission's recommendations—that mentally defective patients should be compulsorily detained in hospital only when this is positively necessary for the patient's own welfare or for the protection of others—has already been acted on [2] In his introduction to the Ministry of Health's report on the year,[3] Mr Derek Walker-Smith, the Minister, says that he looks forward to new legislation "as soon as the difficulties and complexities of the subject permit"

DEMANDS ON HOSPITALS

The annual report shows the year to have been one of solid endeavour The hospitals of England and Wales treated some 55,000 more inpatients than in the previous year, the total being 3,794,000, but waiting-lists, which had been falling in previous years, increased by about 9000 to 440,000

---

[1] Report of the Royal Commission on the Law Relating to Mental Illness and Mental Deficiency H.M Stationery Office, 1957 See *Lancet*, 1957, i, 1187

[2] Circular H M (58)5

[3] Report of the Ministry of Health for the year ended Dec 31, 1957 Part I 1 The National Health Service 2 Welfare, Food and Drugs, Civil Defence Cmnd. 495 H M Stationery Office 1958 Pp 254 12*s*

Last year some 29% more patients were treated than in 1949, though the number of beds was only about 6% greater than at the start of the service

At the end of the year patients awaiting admission to general-surgery departments numbered 131,000, and those awaiting admission to ear, nose, and throat departments numbered 104,000, these two departments thus accounted for more than half of the total waiting-lists The extent of waiting-lists differed greatly between England and Wales and between regions in England In Wales, only in traumatic and orthopædic surgery and in "other" departments were there increased waiting-lists In England, the demand for admissions to hospitals in the Oxford region continued to increase, in contrast, the overall position improved somewhat in the Manchester and Liverpool regions, and waiting-lists increased less than average in East Anglia

In general, both the London and provincial teaching hospitals have much larger waiting-lists in relation to their resources of staffed beds than the non-teaching hospitals

Compared with the non-teaching hospitals, about three times as many patients were awaiting admission to the general medical departments of London teaching hospitals, and three and a half times as many to the same departments of the provincial teaching hospitals For general-surgery departments the difference between the London teaching and non-teaching hospitals was not so great, but at the provincial teaching hospitals the waiting-lists per 100 staffed beds were about two-fifths greater than at the non-teaching hospitals

At the non-teaching hospitals most major departments except ear, nose, and throat, and at the teaching hospitals most departments except ear, nose, and throat and gynæcology, treated more patients per available bed than in 1956 This was due in nearly every instance to reduced stay in hospital, and not to reduced interval between occupation of beds

The number of inpatients admitted to designated mental hospitals was 88,943, of whom 73,499 (82 6%) were voluntary patients, 1318 (1 5%) temporary, and 14,126 (15 9%) certified The total in 1956 was 83,994, of whom 65,637 (78 2%) were voluntary, 1453 (1 7%) temporary, and 16,904 (20 1%) certified

The number of patients admitted to mental hospitals has been rising steadily for many years—the number increased by some 5000 in 1957—but the number of patients resident has begun to fall, owing to the rehabilitation and discharge of patients who have been in hospital for many years, and the shorter stay of newly admitted patients In 1957 the national average of overcrowding, which had been 14% in 1956, fell to 11 9%

HEARING-AIDS

During the year 52,166 new patients were fitted with hearing-aids, bringing the total fitted with aids since 1948 to over 580,000 Following field trials orders were placed for the first batch of 'Medresco' transistor hearing-aids These aids, which weigh just under 3 oz complete with battery, compared with $24^1/_2$ oz with battery case for the original model issued in 1948, are intended in the first instance for children and will not be available to adults until 1959

BLOOD-TRANSFUSION

The strength of the civilian donor panel in the National Blood Transfusion Service amounted to 674,117 at the end of the year, compared with 639,319 a year earlier The number of donations rose from 803,522 in 1956 to 846,202 in 1957 The attendance-rate of general-public donors invited to give blood remained unchanged at an average of 51 8%

CONSULTANTS

Consultants in the National Health Service, including those employed by the Board of Control and in the Public Health Laboratory Service, numbered 6902 at the end of last year, compared with 6739 at the end of 1956 and 5649 at the end of 1950 The numbers receiving distinction awards were as follows A (£2500 per annum), 276, B (£1500), 690, C (£500), 1377

GENERAL MEDICAL SERVICES

During the year the number of doctors admitted to executive councils' lists was 936 and the number deleted was 694 Of those admitted, 601 entered into partnership, including 310 assistants who joined their former principals The total number of doctors practising as principals and providing unrestricted general medical services in England and Wales at July 1 increased from 19,082 in 1956 to 19,343 in 1957 The number of single-handed practitioners (including those with assistants) continued to decline—from 6568 in 1956 to 6381 in 1957 The number of assistants (excluding trainee general practitioners) at July 1, 1957, was 1465, compared with 1546 in 1956 The general decrease in assistants which seemed to have been arrested in 1955 and 1956 has now been resumed

There was a further decrease in the number of patients living in under-doctored areas from 9,500,000 in 1956 to 8,500,000 in 1957 The average number of patients per doctor remained virtually the same—2273, compared with 2272 in 1956

GENERAL DENTAL SERVICES

From 1952 onwards the volume of treatment given under the general dental services increased at the rate of 8–9% a year, but in 1957 the increase over the previous year was only 5 2% This was nevertheless appreciably more than the increase in the number of dentists in the service (2 3%) At the end of the year 16,113 dentists were on the Dentists Register, compared with 16,007 at the end of 1956

EFFECTS OF RADIATION

M R C Committee's Comments on U N Report

THE committee appointed by the Medical Research Council to report on the hazards to man of nuclear and allied radiations has prepared a statement [1] on the United Nations report published last week [2]

In general the U N report follows the same lines as the reports of the M R C committee and the United States National Academy of Sciences, both of which were published in 1956 "We have derived considerable reassurance", the M R C committee say, "from the fact that, in a field of science that is so difficult and, as yet, relatively little developed, the three major reports on this subject are so substantially in agreement with each other" In the past two years much additional information has been collected, but it has led to no major revisions of opinion "rather it has strengthened and amplified the tentative conclusions and predictions in the two earlier reports" Both the 1956 reports confined their attention to conditions in technologically well-developed countries of the Western world the U N committee has considered the problem on a worldwide basis

---

[2] See *Lancet*, Aug 16, 1958, p 360

DOSE AND EFFECT

From their reading of the U N report, the M.R C committee derived the impression of a predisposition to favour the view that induction by radiation of such possible long-term somatic effects as leukæmia and cancer was a process comparable to that of induction by radiation of genetic mutations, and that there was, in consequence, no threshold dose below which there was no induction of such somatic effects "In our opinion, this view tends to tinge the interpretation of subsequent data, despite the earlier recognition of the equally tenable alternative view" The M R C committee add

> "In our view, it is not possible at this present time to decide whether there is or is not a threshold dose concerned in the induction of leukæmia and cancer, and the only scientific attitude to the problem at present is one of suspended judgment Nevertheless the significance of the alternative points of view in determining the ultimate assessment of risk should be clearly understood so that those who have the responsibility for acting on such assessments should be fully aware of the alternative possibilities that need to be taken into account"

GENETIC EFFECTS

The M R C committee accept the view that the knowledge now available indicates that "there is at present no known threshold of radiation exposure below which genetic damage does not occur", that "the experimental foundation for a linear dose relationship is fairly well established at moderate doses but is increasingly meagre at lower doses", and "that it is prudent to assume as much hazard as is implied by a linear relation between mutation and gonad dose"

In the difficult matter of estimating the amount of radiation required to double the mutation-rate of a representative number of human genes the U N committee arrived at a range of possible values similar to that put forward in the M R.C report They suggest a range of 10–100 rad, compared with the M R C's figure of 30–80 rad

DIAGNOSTIC IRRADIATION

Both the 1956 reports drew attention to the large contribution made by medical diagnostic irradiation to the genetically significant population dose The M R C committee had put this contribution at some 22% of the natural background, with the reservation that this figure should be regarded as tentative and probably a lower limit They now say that "further information has confirmed us in this reservation so that we are now willing to accept that the genetically significant dose from this source may be as much as 100 per cent of the natural background radiation in countries with extensive medical facilities" It is reassuring to note, they add, that there is agreement that most of this genetically significant dose comes from a few types of radiological examinations

FISSION PRODUCTS

Since 1956, it has become recognised that the deposition of fission products from the reservoir in the stratosphere is not uniform over the globe, but that countries between 30° and 50° N may receive a deposition about three times greater than the worldwide average In this country the annual fallout-rate of ^{90}Sr has increased very little since 1954—from 2 to 2 5 microcuries per sq km In New York State the increase has been from 3 to about 4 5 microcuries per sq km

The U N committee concluded that, for the same degree of fallout, the average concentration of ^{90}Sr in the bones of those living on a plant-type diet may be up to 5 or 6 times that in the bones of those on a milk-type diet The M R C committee consider that, on the available evidence, this is a reasonable conclusion, and they think that the methods chosen for calculating future fallout levels are also reasonable, "but the soundness of the conclusions reached necessarily depends on the validity of the initial assumptions"

ASSESSMENT OF THE HAZARDS

In 1956 the M R C committee said that the maximum allowable concentration of ^{90}Sr in the bones of the general population, with its proportion of young children, should not be greater than 100 strontium units (S U) The special subcommittee of the United States National Academy of Sciences appointed to consider this matter were unable to reach agreement, but the general belief was that 50 S U would produce no perceptible effect. The M.R C report said that immediate consideration would be required if the level in the general population showed signs of rising greatly above 10 S U The mean marrow fallout doses over 70 years given in the U N report are equivalent to strontium levels ranging from 2 3 S U as the average in bones of people on a milk-type diet (assuming weapon tests stop at the end of 1958) to 240 S U in bones of those on a plant-type diet (assuming weapon tests continue under certain hypothetical circumstances until equilibrium is reached in about 100 years) The significance to be put on these figures depends on the existence or absence of a threshold, and "in the present state of knowledge it is not possible to decide between these alternatives"

HOSPITAL ADMINISTRATIVE AND CLERICAL STAFF

AT the end of last year, in a report to the Ministry of Health and the Department of Health for Scotland, Sir Noel Hall recommended revision of the grading structure of the administrative and clerical staff of hospitals [1] The Ministers referred his proposals to the appropriate Whitley Council. The management and staff sides accepted Sir Noel's proposal that the seven existing lettered grades A–G should be replaced by the following five new grades clerical, higher clerical, junior administrative (which is to be a training grade), general administrative, and senior administrative

The salary scales of the present grades are

A1	£206–£453	D	£556–£659
A2	£206–£515	E	£623–£753
B	£299–£546	F	£693–£862
C	£515–£597	G	£802–£983

The scales for the proposed new grades, which have been accepted by both sides of the Whitley Council, are

Clerical grade	£230–£600
Higher clerical grade	£575–£735
Junior administrative grade	£575–£725
General administrative grade	£750–£1000
Senior administrative grade	£1000–£1240

The management and staffs sides were, however, unable to agree on the manner and pace of introducing these changes, and the disagreement was referred to the Industrial Court. By their recent award [2] all staff are to remain at their present rate of pay until each employing authority has reviewed certain posts according to the new grading structure, this review is to be completed before Nov 1

---

[1] *Lancet*, 1957, ii, 1104

[2] Industrial Court (2701) National Health Service.

Salaries will be raised to the new rates in stages The first increase will be retrospective to July 1, 1958, and the new rates must be completely introduced by July 1, 1959, for the clerical grades, by July 1, 1960, for the general administrative grade, and by July 1, 1961, for the senior administrative grade Immediate increases will vary from £22 to about £100 a year

Negotiations on "designated" posts, including hospital secretaries, are continuing The award affects only hospital officers and does not apply to other National Health Services clerical and administrative officers such as those serving executive councils

Public Health

Cholera in Asia

Cholera has broken out in Khatmandu, Nepal This is the first cholera epidemic reported in that country since the beginning of the century

The cholera situation in Asia, according to W H O, is the most serious in years Cases and deaths are twice as numerous as last year in India and East Pakistan, and an epidemic has struck Thailand for the first time for many years Cholera has also been recorded in Cambodia and Burma Cumulative totals up to July 31 were as follows

	Cases	*Deaths*
India	29,372	12,851
East Pakistan	10,386	6644
Thailand	8964	1190
Cambodia	3	0
Burma	4	2
	48,729	20,687

The Indian Minister of Health said last week[1] that more than 16,000 people had died of cholera and smallpox in Bihar and West Bengal in the first six months of this year Smallpox was also epidemic in Uttar Pradesh but figures were not yet complete Unofficial estimates put cholera deaths in the Katmandu Valley of Nepal at more than 300

No Fluoridation in Worcestershire

The public health committee of Redditch accepted the medical officer of health's recommendation to put fluorine in the town's water-supply, and similar decisions were reached by the two Bromsgrove councils, who also receive water from the East Worcestershire Waterworks Company But the company has rejected their requests because it is uncertain about the legal situation The manager is reported[2] to have said that his board had decided to take no action until the results of the Ministry of Health's experiments in three other test areas (Watford, Kilmarnock, and Anglesey) were announced "I doubt whether there is a single undertaking in the country that would take any notice of such appeals until the Ministry report is issued," he added The decisions at Redditch and Bromsgrove had not been met by any such organised protest as led Andover Borough Council to stop the testing of fluoridation[3]

Mustard Gas Burns?

On Aug 4 two young men were walking with a dog on the Western Heights, Dover[4] The dog apparently burned its mouth while in some long grass, and later it had to be destroyed Next day a rash appeared on the arms of the two youths They went to hospital, but were not detained The possibility that they came in contact with mustard gas is being investigated, but this explanation is now thought unlikely

In England Now

A Running Commentary by Peripatetic Correspondents

The second brood of swallows are well on the wing There has not been time for a third this year I am no ornithologist. the swallows have always been just part of our pattern of lif and have shared this house with the dalesmen who watche before us for the past four hundred years I do not understan why they should choose to come back or how they do it ther are some things over which one should rest content About th beginning of April, when the first lambs are being born aroun us in the valley, we start to look down the long silver ribbon o Windermere for the silhouettes of wavering flight out of th warming sun The winters are long in Lakeland, grim an austere on the fells The swallows mean more to us than bird returning It was April 21 when they came this year th Queen's birthday, the day the children came back fro abroad, the day the sun was shining Back to the same set o nests in the stable, the twittering around the chimney pots the curving flight to the beck for mud to mend the lip of th nest, the pantomime of courting, and then down to seriou business on a clutch of eggs

For as long as I can remember the stable has held just on pair of swallows they surely cannot be the same pair year afte year How do they decide which ones shall inherit the nes next season? Eight or a dozen youngsters fly away in autumn two birds come back in spring No fighting for possession, n queuing up, no ribbon development along the stable beam Somewhere and somehow these things must be decided perhaps around the pillars of the Parthenon on Christmas Day, perhaps along the timelessness of the Nile Two birds come back in spring There are days when I should like to know the answers Where the rest of them have gone? How many seasons one pair are here? Ring them with metal bands? But my heart would rather not know For who were all the people laughing through this house for its four centuries on the fellside, watching the swallows where did all their children go, and how was it handed down? They are gentle ghosts who deserve their rest Who will care in 2358 for the brief season of our day? They will watch the swallows still The second brood are well on the wing I know now when they will go It will be the third week in September the week when eighteen years ago the sky was weaving with the swooping tumbling flight of youngsters to decide who should come back to England in the spring

* * *

I came into our hospital the back way the other morning (my usual short-cut between the departments of psychiatry and radiotherapy) and saw, standing between these two buildings, the back half of a red double-decker bus Nobody knew how it had got there, or who put it there, or why, and speculation ran wild

Perhaps it was something to do with the bus strike—the busmen cutting off half their bus to spite the other half, or was it a rather embarrassing gift from one of the inhabitants of the nearby Fen villages who had run amok with a large saw, and was distributing half buses here and there to his friends and acquaintances?

We thought it might be connected with radiotherapy, as it stood between their main building and the shed which houses their precious noisy and extremely temperamental synkrotron Was it, perhaps, a new synkrotron, heavily disguised, one that did not need a lead wall around it, 6 ft thick, or the ministrations of two full-time highly qualified physicists and their minions to coax a few hours' work out of it weekly? But the radiotherapy director disclaimed it

The most likely explanation seemed to be that it was some sort of psychotherapeutic aid—a solid symbol on which the patients and psychiatrists could hang their fantasies The castrated appearance of the bus was thought to support this view But the psychiatrists were as mystified as the rest of us

The explanation turned out to be straightforward and slightly disappointing The half bus was a present from the local coach company to the department of physical medicine to help in the rehabilitation of their patients, and its final home is outside physiotherapy, where it looks both useful and decorative, with a red rose in a tooth-mug at the foot of its stairs

The Neo-medical Travel Agency has been closed. I really cannot understand why To say the least it is unfortunate for we had a very satisfied, well-informed clientele

We used to take our clients as far as mid-Channel before putting them under (with hypnotism I mean), but we soon realised that we could cut expense by not transporting them at all, so they just used to come to the agency We bundled them upstairs, luggage and all, laid them down, and put them under, and there they lay for their time—two or three weeks, whatever their holiday period was We tube-fed them, nursed them carefully, gave them twelve hours' sleep and twelve hours of movies (full-colour local views including the hotel) We played them tapes with all the relevant local vital statistics, which made them the most knowledgeable travellers of an agency, and they all turned out nut-brown with judicious dosing with ultraviolet rays (no painful burns or peeling)

It was a pleasure to watch them at the end of their time going forth, their minds full of the pleasures of France, Spain, Greece, or wherever they thought they had been, well fed, well tanned, and well rested Quite a contrast to the peeling, harassed, confused traveller of other agencies who needs a fortnight's rest to recuperate from his holiday

Just because we couldn't get one under, all the rest have to suffer We tried to explain to him, but he wouldn't be reasonable He reported us to the authorities and they closed us It is all most disappointing, and I really cannot understand their attitude I was going to say "it's a strange world," but some of us have now come to feel that there really isn't anything farther than mid-Channel

* * *

Once again my hayfever season has ended and the year's "most effective ever" drug has been assessed It did not seem to make a great deal of difference to my streaming nose and eyes, but at least it did not send me to sleep (The fairly early end of my surgical career may well have been influenced by the fact that on one bright July day, when well dosed with the latest antihistamine drug, I began to snore in the operating-theatre) In early summer people ask my advice about treatment They wait patiently while I try to find one of my five handkerchiefs, then sigh resignedly and go away One day last month I was sneezing happily away in the train, when I had a disturbing thought "You just look ridiculous, my friend" Observe the method, no thought of treatment, no concern, and certainly no sympathy Within minutes the attack had ended and since then I have found the result can be repeated Perhaps this new approach is a good one, or perhaps the latest wonder drug deserves more credit than I have given it

* * *

An octogenarian Yorkshire lady stopped me in the street one day "Hey doctor! My granddaughter's got spots on 'er face You know the name The one like 'orses and carriages What d'yer call it? Oh, yes, acne" Or does she spell it 'ackney?

* * *

Problems of irradiation
Are disturbing every nation
Bent on human preservation
Genetic hazards must be measured
If fertility is treasured.

People potter round with counters
That they cannot understand,
Write alarmingly to papers
About death upon the land.
They know nothing of the meaning of the röntgen and the rem,
The rep and rad are so much Greek to them
And when faced with R.B.E
They are hopelessly at sea

But mutation of the gene
Doesn't worry Aberdeen
It will populate the planet
In despite of rays from granite

Letters to the Editor

CHILDREN IN HOSPITAL

SIR,—The provision of a satisfactory hospital service for children concerns us all The report set out by the Royal College of Physicians (April, 1957) to guide "individuals and authorities who are planning the care of children in hospital" has been sadly overlooked It stated that "there is no doubt that special children's hospitals offer the best service for children because the staff at all levels and in all departments is attuned to the special needs of the sick child" Pædiatric physicians and surgeons must be grateful to Professor Illingworth and to *The Lancet* for its leading article (July 26) for re-emphasising these needs to the medical world, and to Mr Denis Browne and Dr Helen Mackay for bringing the facts before the public through correspondence in *The Times* (Aug 6 and 11) The threatened closure of children's hospitals strikes horror in the hearts of those who can best understand the special needs of ill children

For a long time cold war has existed between children's hospitals and fever hospitals, but, now that Dr Emond (Aug 9) tells us that fever units admit, and should admit, cases of pneumonia and meningitis, he shows how false is the separation of patients into these two special hospitals - Pædiatric units admit these cases too, and a children's hospital with suitable isolation facilities for "infectious diseases and notifiable infectious diseases" could provide a comprehensive hospital service for children in which specialists in all branches of pædiatric medicine could cooperate The Ministry of Health stated[1] that "it is of the utmost importance that hospitals and wards for infectious diseases should be closely associated with pædiatric departments" and the Royal College of Physicians report endorses this view and urges that pædiatricians be appointed to fever hospitals when vacancies arise and that blocks for infectious fever should be included in the development of large pædiatric units This will not come to pass if the Minister pursues his policy of closing children's hospitals URSULA JAMES

SIR,—I am delighted to know, from Mr Braithwaite (Aug 16), that the South West Metropolitan Regional Board no longer intend the immediate closure of Queen Mary's But this is news On July 23 the chairman of the regional board, Mr A G Linfield, told the chairman of our management committee, Major H J Wells, that it was the intention to "run Queen Mary's down" over the next few months and that the Fountain Hospital would move in early in 1959 The chairman of the Surrey and West Sussex area committee of the board, Major-General L A Hawes, was present at this interview, but Mr Braithwaite was not If any charge of inaccuracy is to be made, therefore, it should not be directed at me

Mr Braithwaite's second charge contains a half-truth The chairman did refuse, as I reported in my letter of Aug 2 to entertain the idea of getting expert pædiatric advice It was *after* this that the board had second thoughts, and invited Professor Moncrieff I entirely concur with the views in Mr Braithwaite's last paragraph, but the inaccurate and intemperate statements have not been mine Personal attacks will not deflect me, or I hope others, from sober and careful study of this important issue in all its aspects

Queen Mary's Hospital for Children,
Carshalton, Surrey

UNSATURATED FATS AND IMPORT RESTRICTIONS

SIR,—Recent work has established a high probability that human arterial disease is influenced by dietary fats, and has proved that the replacement of saturated fats by polyethenoid oils tends to reduce the cholesterol content of human serum [1 2] Since a dietary change of this type is almost certainly harmless, and safer than any excessive restriction of fats, it seems desirable to advise patients with raised blood-pressure or anginal pain to make this change as far as is reasonably practicable Thus butter and cooking-fats may be replaced by corn oil (from maize), or by the more expensive sunflower or safflower oils, and the saturated fats may be further reduced by substituting skim-milk powder and skim-milk cheese for the normal products

I find, however, that patients in Britain are unable to purchase corn oil, and have difficulty in finding other flavourless oils with a high content of polyethenoid acids On inquiry from a leading London store I am informed that, owing to Board of Trade decisions on goods requiring dollars, " corn oil does not at present figure in goods to be bought from abroad "

It would, I suggest, be helpful to the numerous British people suffering from arterial disease (and possibly those from certain other serious diseases, as suggested by Sinclair [3]) if some correspondent would mention in your columns such edible " unsaturated " oils as can be bought retail in Britain, and their average content of linoleic or other polyethenoid acids If no refined oils are available, except olive oil which is useless for this purpose, and West African groundnut oil which is described by Hilditch as low in content of linoleic acid,[4] could the medical advisers to the Board of Trade consider allowing the import of corn oil from Canada or the U S A ? It seems at least possible that this would reduce the rate of ageing of some of the most active people in the nation

R B BOURDILLON

MODIFICATION OF EGG-YOLK FATS

SIR,—The forcing of domestic poultry to consume sunflower seeds instead of those grains which are natural to them, in order that human beings may themselves consume an unnatural product in the form of their eggs so altered, breaks every evolutionary law and can therefore never hold the solution to the problem of coronary disease

I have tried to point out in a small publication [5] that the Darwinian theory of evolution teaches us that we should consume those fats that we individually like, whether animal or otherwise, in just the amounts we desire, always assuming that the fats have not been greatly altered from their natural state or so mixed with other foods that we are unaware we are eating them

Securing an unnatural product by the means described in your issue of Aug 2 (p 243) is therefore doomed to failure from the start How can the tactics be correct when the overall strategy can be proved to be incorrect? How can the tree be right when the wood can be proved to be wrong?

T L CLEAVE

INTRACUTANEOUS RIBONUCLEASE IN CHRONIC MYELOCYTIC LEUKÆMIA

SIR,—In the blood of patients with chronic myelocytic leukæmia I have observed many dead and dying leucocytes Dead leucocytes may stimulate proliferation of bone-marrow I have shown that the urinary ribonuclease activity of patients with chronic myelocytic leukæmia is several times higher than that of normal persons [1] It seems that the tissues of these patients lose this enzyme abnormally, consequently enzyme autolysis of granulocytes is diminished Perhaps that is why many dead leucocytes are present in the circulating blood

I have made good the deficiency of ribonuclease by injecting it intracutaneously (0 5–1 mg daily) in patients with chronic myelocytic leukæmia The leucocytosis diminished, the spleen became smaller, and the general condition of the patients improved Further researches are in progress

JULIAN ALEKSANDROWICZ

A WATER-SOLUBLE DRESSING GAUZE

SIR,—Gauze impregnated with a soft paraffin, and made up in boxes which can be sterilised and sealed, has long been used for all types of wounds It can be produced in many different sizes and is easily handled From the patient's point of view, the dressing does not stick, nor does it cause discomfort It can be used both on superficial lesions and in deep cavities I have used it extensively in the casualty department of the Bristol Royal Infirmary

In a busy department I have tried to simplify the dressing routine as far as possible Sterile paraffin gauze was used as a dressing for burns, incisions, and most abrasions and open wounds Other dressings are used also, but paraffin gauze was widely employed

It was found to have some disadvantages The soft paraffin adheres to instruments and gloves and makes them greasy so that wool or other materials stick to the forceps or hands It cannot be washed off by immersion in sterile water unless it is either very hot or contains some solvent for soft paraffin In many cases wounds which were dressed with paraffin gauze for more than about five days became very moist and the granulation tissue very unhealthy and œdematous The skin edges became wet and in some cases these became reddened and even blistered, preventing the control of infection and so delaying healing There were some wounds in which a spread occurred from the lesion to normal areas—a most irritating and alarming procedure for the patient This could be prevented by reducing the length of time the paraffin gauze was employed, and by taking care that only one layer was used It very soon became obvious that gauze which was over full of soft paraffin was more likely to cause trouble

Moreover, the cleansing of the wound became very difficult The paraffin on the skin around the wound must be removed thoroughly but this can be done only by fairly heavy and repeated swabbing

In cooperation with Mr G H Darling, our chief pharmacist, a dressing gauze which seems to have all the advantages of paraffin gauze, without its disadvantages, has been developed To keep the wound dry one must have a gauze that will mix with both the serum of the wound and the skin secretions It must not block the openings of the sweat glands It must not stick to the wound and it should be easily removed from gloves and instruments

The macrogol gauze,* which we have used for approximately

---

[1] *Lancet*, 1958, i, 641

* *The macrogol gauze base being used consists of*

Polyethylene glycol 300	15 oz
Polyethylene glycol 1500 GEN	3 oz
Polyethylene glycol 4000	2 oz

This gives a conveniently firm dressing that softens readily at body temperature eighteen months, is not harmful to the tissues, does not stick, and is water-soluble Because of this the moisture in the wound and surrounding skin can pass through the gauze into the dressings outside it It does not make the skin moist, and delayed healing and sensitisation are therefore unlikely It can be prepared and used in a similar manner to paraffin gauze It is easily removed from the hands, instruments, or the patient's skin, by gentle swabbing with water or saline It causes a minimum of inconvenience for the dresser and of discomfort for the patient

We have used it for both daily and less frequent dressings and it does not appear to delay healing nor does it give rise to any unpleasant odour The macrogol gauze can be prepared with any desired percentage of an antibacterial agent We have used it with 0 2% nitrofurazone in it, but this was abandoned when reports of sensitivity appeared.

Many people are dissatisfied with preparations of soft paraffin gauze and I am sure that these difficulties must have been overcome in a diversity of ways, but in our experience macrogol gauze is a very satisfactory dressing with a wide range of application

After clinical trials had shown the gauze to fulfil all the claims made for it, we gave the formula to Messrs Smith & Nephew, and we are now using their preparation called 'Carbonet'

AN UNUSUAL SOURCE OF MERCURY IN PINK DISEASE

SIR,—The relation between mercury and pink disease has been much discussed, and though the consensus of opinion seems to hold that a direct causal relationship is "not proven," there is good evidence that the frequency of the association is more than incidental The sources from which infants may absorb mercury are usually fairly well defined (teething powders, mercurial ointments, vermifuges, &c) The case described here seems to be of interest since it involves an unusual source of mercury absorption in the infant

A boy child, aged $2^{1}/_{2}$ years, was admitted to the Hospital for Sick Children, Great Ormond Street, under the care of Dr Wilfrid Sheldon, in May, 1958, after a series of epileptiform convulsions He was a third child, and there was no history of birth trauma nor any family history of neurological disease or fits

His development had been possibly slightly retarded (he sat up at ten months, walked at twenty months, and at the age of two years spoke only a very few single words), but he had been otherwise well until October, 1957 At this time the whole family had influenza, and he had an acute pyrexial illness and a convulsion. He was admitted to the local hospital but made a quick recovery and no abnormality apart from his mental slowness was noted

The child remained well until April 29, 1958, when quite suddenly he had a series of convulsions which continued for thirty-six hours until controlled by sedation He was admitted to a local hospital where it was thought that he had become both deaf and blind and where a lumbar puncture was performed and found to be normal

On arrival at Great Ormond Street he was fully conscious but very irritable and tended to lie in the prone position with his legs curled under him and his eyes turned away from the light He had a cold pinkness of his extremities, a mild desquamating rash over the lower part of his trunk, and an angular stomatitis His pulse-rate was 120 and his blood-pressure 130/90 mm Hg Examination of the central nervous system revealed no localising abnormality, he could see and hear well, but his mental state was obviously retarded for a child of $2^{1}/_{2}$ years Investigations included chest and skull X-rays, electroencephalography, serum-calcium, phosphorus, urea and sugar, urine for abnormal metabolites, Wassermann reaction, and blood-count, which were all essentially normal, but the erythrocyte-sedimentation rate was 40 mm in one hour, and a twenty-four-hour specimen of urine showed an excretion of 207 μg of mercury

A further history taken from the parents at this stage did not reveal any access to mercury from any of the usual sources, but on close questioning it was discovered that just before the onset of the fits the lawn had been dressed with lawn sand The weather had been fine at this time and it was some four days before rain washed the sand into the earth. In the meantime the child had been playing on the lawn most of each day The child was not seen to eat the sand, but later in the ward he showed the usual tendency of his age to put everything in his mouth A specimen of this lawn sand was found to contain about 1 part in 50,000 of mercury

The child's subsequent progress was slow but uneventful He remained irritable for some days and showed a tendency to an inverted sleep rhythm with wakefulness at night and drowsiness in the day Before discharge the urinary mercury excretion was 17 μg in twenty-four hours

When last seen in June his good progress had been maintained, though he was backward in his speaking and had had two short episodes of urticaria

Mercurised lawn sand is a dressing applied to lawns to kill unwanted moss Its use is quite extensive in this country The possibility of absorption of mercury from this source has not, to my knowledge, been recognised and I hope this case will draw attention to the fact

I should like to thank Dr Wilfrid Sheldon for permission to report this case and for his help and advice in the preparation of the text

LECTURES ON TAPE

SIR,—I have just read your note[1] about the suggestion of Graves and Graves[2] that there should be a central library of tape-recordings and a collection of machines for hire

Each month about 30,000 American and 1000 Canadian doctors are doing just what this note suggests—i e., keeping up with advances in medicine and surgery by listening to tape-recordings prepared by our organisation.

The Audio-Digest Foundation (a non-profit subsidiary of the California Medical Association, whose excess reserve funds are contributed to America's 79 medical schools) issues 5 different series of programmes Subscribers to surgery, internal medicine, obstetrics-gynæcology, and pædiatric programmes receive a new hour-long tape every two weeks, those in general practice receive new programmes each week

The tape-recordings themselves survey the current world literature and provide the rural practitioner with expert scientific lectures by leaders in world medicine Each programme contains at least 2 fifteen-minute lectures by an expert in his chosen specialty

I write to let your readers know how many of their American and Canadian colleagues are keeping up with medical advances, and to suggest that these tapes (with appropriate equipment) might be set up in central locations throughout the British Isles for the use of interested doctors

In America the annual subscription to the specialties is \$81 50, and for the weekly general-practice series it is \$162 At present, customs and excise difficulties prevent the importation of our programmes into England, but with enough interest from the British medical profession it is possible that these obstacles might be overcome

BIOCHEMICAL CONCEPTS OF SCHIZOPHRENIA

SIR,—Dr Smythies, in his interesting review (Aug 9), refers to the observations of Örstrom and Skaug[1] upon adenosine triphosphate (A T P) turnover by the blood cells of schizophrenic patients So far as is known no report has appeared since 1951[2] which bears upon these findings We have found no differences in the rates at which ^{32}P, added to whole blood incubated at 37°C for 60 minutes, is incorporated in the A T P, inorganic phosphate, 2 3-diphosphoglycerate, and hexose monophosphate fractions of six female psychiatric patients (aged between 18 and 35, three of whom were suffering from schizoid disorders and three from neurotic disturbances) The uptake by the cells of all six subjects are within ± 1 standard deviation of the mean values obtained on 6 separate observations with the blood of five normal subjects in this laboratory Neither was there any difference in the phosphate content of the fractions examined

J L H LAITY

DEATH OF A BOXER

SIR,—A number of physicians have written that in long associations with both amateur and professional boxing they cannot recall any cases of cerebral injury Having examined many boxers over many years, I have seen numerous cases of cerebral and other injuries in amateur and professional boxers and reported them in detail In this letter I shall confine myself to a few selected references

In 1942 I described[3] a young amateur boxer who died as a result of a blow to the jaw The fight was held under the supervision of the appropriate boxing authorities Necropsy revealed a laceration of the left temporal lobe and an extensive intracranial hæmorrhage

In 1947 I reported[4] the death of a 23-year-old professional boxer who " participated in a public fight under the auspices of the Board of Control for Professional Boxing and Wrestling ", with a medical officer in attendance He was knocked out and remained unconscious for several days An emergency operation was performed and a right-sided subdural hæmorrhage drained The patient died a fortnight later, postmortem examination revealing some old blood clot adhering to the inner surface of the dura mater, and purulent meningitis

In 1956 I mentioned[5] 2 cases of boxing injuries to the mid-brain, one concerning a young man who died on the 21st day after a fight in which he was knocked unconscious At necropsy tissue softening throughout the brain-stem was found The other case was that of a 24-year-old boxer who had been in the ring for many years and who, following a fight, suddenly noticed tremor of the left hand which rapidly spread towards arm, shoulder, and head, leading within a short time to the development of a typical parkinsonian picture

In 1948 I detailed[6] 10 cases of boxing injuries to the eyes in previously healthy men, among them tears in the iris with hyphæma, cyclodialysis, traumatic choroiditis followed by detachment of the retina, choroidal tears near the fundus, hæmorrhages in the vitreous body, widespread macular changes, and rupture of the lamina elastica posterior These findings were subsequently corroborated by Doggart[7]

In 1944 I told[8] the story of the fatal collapse of a boy, aged 10, after a regulation boxing fight, necropsy revealing an organised occluding thrombus in the coronary artery There were fresh extravasations of erythrocytes between intima and media around the occluded area The latter had, I think, been caused by the blows received during the boxing fight and initiated the chain reaction which led to the child's death

In 1950 you published[9] an editorial which I felt summed up the argument In 1956 I made a comprehensive review[10] of the evidence as it was then available in the literature

In case it should be argued that the percentage incidence of boxing injuries is small, I refer to two competent electro-encephalographic studies on amateur boxers[11, 12] The implications of these two investigations are truly devastating in that they prove a much greater vulnerability of the brain to the kind of blunt traumata that are common in boxing than had previously been suspected

The medical facts about boxing are no longer in question But it is certainly a problem of far-reaching psychological and moral significance that issues like this which call for radical social action on the part of our profession, still find vociferous defenders

ERNST JOKL

SURGERY FOR PULMONARY TUBERCULOSIS

SIR,—I am very interested to read in your report of the conference on chest diseases (July 19, p 142) that the therapeutic compass is pointing away from surgery in pulmonary tuberculosis That, in my view, is not necessarily so for the patient whose career is an arduous one and who wishes to pursue it (for example, the fighting soldier) or who wishes to emigrate to a country with stringent rules barring tuberculous subjects

Admittedly there is normally no case for resection, in suitably localised reversible disease, in the absence of drug resistance In the past non-cavitated apparently solid disease, thought to be irreversible, may have been resected because it was not appreciated that some such lesions may show almost complete radiological resolution after 12 months or more of chemotherapy

In the first 75 Gurkha patients with tuberculosis on long-term chemotherapy who were referred by me from Malaya for partial lung resection in the Army Chest Centre, 8 (10 6%) were removed from the surgical list after the following periods of chemotherapy (months) 23, 23, 21, 21, 17, 16, 15, and 12 The unusual drug regime used was streptomycin (1 g daily) and isoniazid (2 × 100 mg daily) for at least 30 days Thereafter, both drugs in the doses stated were given together on the same day every second day[13, 14] Radiological resolution proceeded so far that surgery was no longer considered necessary The proportion of withdrawals is less than some surgeons experienced in the days of long surgical waiting-lists and when long-term preoperative chemotherapy was the exception in this country

It is not disputed that with long-term chemotherapy, in the absence of emergence of resistant strains of *Mycobacterium tuberculosis*, bacteriological examination of apparently irreversible lesions shows a progressively high sterilisation-rate of such lesions the longer the preoperative course of chemotherapy Nevertheless in my opinion this must not give cause for complacency, especially when young people are treated with long-term chemotherapy alone, particularly when we consider the increased, almost alarming, rate of notifications in the older age-groups, indicating the resurgence of active tuberculosis in the vicinity of pulmonary lesions formerly considered quiescent or healed

There is, of course, a case for not advising surgery for patients on long-term chemotherapy in the absence of resistant strains, for there is presumptive evidence that *Myco tuberculosis* will be exterminated in most, if not all, lesions

Nevertheless, the patient should also be informed of the excellent results of resection in suitably localised irreversible disease in these days of skilled thoracic surgery, negligible operative mortality-rate, and slight incidence of complications As your report rightly says, not only the age and sex of the patient but the extent, irreversible character, and destructiveness of the disease must be considered To that must be added the patient's career, with particular reference to careers involving severe strain and possible emigration

In certain countries evidence of tuberculosis of the lungs bars acceptance of potential immigrants The reaction of such authorities to the applicant with radiological evidence of pulmonary tuberculosis, no matter the duration of successful long-term chemotherapy and however fit and bacteriologically negative he may be, can be well imagined

It seems there will always be absolute indications for resection in pulmonary tuberculosis—e g , destroyed lung, bronchostenosis, bronchiectasis, rigid cavities, &c) It is my belief that the case for resection is as strong as ever, the only difference being that the time for surgery in many of the specially selected cases may be much later than formerly This aspect of the case for surgery should be represented to the patient with the same skill as the opposite view and with special reference to his future career After all it is the patient with whom the final decision should rest Failure to give him an impartial briefing on both sides of the question of long-term chemotherapy with or without resection means that the pendulum is swinging into the dark and the compass bearing is not reliable

JOHN MACKAY-DICK

FAILURE OF DETERGENTS TO DISINFECT

SIR,—We were most interested in your annotation of Aug 9 regarding " failure of detergents to disinfect "

There is, of course, evidence to support the claim that quaternary ammonium compounds show greater activity against gram-positive than gram-negative organisms, and it is also true that *Pseudomonas pyocyanea* seems to be one of the most resistant organisms, but at the same time the evidence does indicate that, in the dilutions recommended for ' Zephiran ', even *Ps pyocyanea* should be killed within ten minutes That this is so is also pointed out by Plotkin and Austrian [1] whom you quoted They reported 40 cases of bacteræmia (not septicæmia) due to *Ps pyocyanea*, the result of unsatisfactory skin disinfection using swabs saturated in a 0 1% solution of zephiran It was pointed out that all of them were due to this organism growing in a solution of zephiran from which most of the quaternary had been adsorbed into swabs stored in it so that the concentration of the solution was lowered to an ineffectual level They emphasise " the potential hazard of infection from the improper use of such solutions " We are therefore dealing with errors of technique rather than the ineffectiveness of the disinfecting agent

I believe that in this country quaternary ammonium compounds are frequently used for the sterilisation of heart-lung machines and up to the present this appears to have proved completely successful Again, this seems to suggest that matters of technique might have been at fault

You mention that quaternary ammonium compounds are not very satisfactory skin disinfectants and for this purpose 2% iodine in 70% spirit is still supreme It is interesting to recall that Gardner [2], while supporting the efficacy of tincture of iodine for skin sterilisation, also concluded that the detergent zephiran in 70% ethyl alcohol gave satisfactory disinfection in 30 to 45 seconds

While fully recognising the problem posed by the difficulty in eliminating *Ps pyocyanea* because it is the most resistant organism to quaternary ammonium disinfectants, it is a rather widespread generalisation to conclude that quaternary ammonium disinfectants are as specific in their action as sulphonamides I feel that the conclusion should be that just as heat sterilisation must be done correctly in order to prevent the innumerable failures that have been observed because of insufficient heating or faulty autoclaves, &c , so similarly the quaternary ammonium compounds must be used with the knowledge of their properties and according to the suggested routines in order for them to prove the effective agents they are

DEVELOPMENT OF RESPIRATORS

SIR,—I was very interested to read your leader of Aug 9, in which you attribute priority for the inception of the alligator principle in respirator cabinet design to Both and imply that it was his model which prompted the manufacture of cabinets of this type in the United Kingdom It seems fair to point out that, independently and without any knowledge of Both's alligator model, Capt. G T Smith-Clarke in Coventry in 1952 conceived, designed, and built a quarter-scale model of an alligator respirator—later put into production as the Smith-Clarke cabinet respirator [1, 8]

It was in the following year (1953) that the Ministry of Health bought for trial two of Both's new alligator-type machines [2] Again, in 1952, Captain Smith-Clarke modified (with due regard to the draft performance specification of the Ministry of Health, breathing-machines group) five of the original Nuffield (Both) respirators [3] His pattern of modification was later adopted as the standard scheme for the country at large The items in this modification did not at first include a split-head which was added at a later stage—i e , after Captain Smith-Clarke had already designed his alligator

Whilst on the subject of Captain Smith-Clarke's work it is tempting to recall some of his other contributions to respirator practice in *this* country, such as the ingenious hand-pumping arrangement on the modified Nuffield motor-bellows unit,[3] his infant and child-size cabinet respirators, his adoption of the wrap-over neck collar, his positive-pressure attachment for use when a cabinet is opened,[4] his mechanised inspiratory-expiratory valve and arrangement for optional negative pressure as fitted to his intermittent positive-pressure respirator,[5] his robust and powerful foot sucker,[6] and finally the Smith-Clarke standard testing unit.[7]

The story of these developments is set out in the James Clayton lecture [8] given in 1956

Whitley Hospital, Coventry

J F GALPINE

ULCERATIVE COLITIS

SIR,—Dr Sim and Mr Brooke (July 19) seem to me to misrepresent the current psychosomatic concept of the ætiology of ulcerative colitis Do they really believe that dependable information can be got (*a*) by questionnaire, (*b*) retrospectively, and (*c*) by seeking answers to questions which are not relevant to the psychopathology of the disease—notably the incidence of anxiety and depression ?

I can think of no important contribution to the subject in recent years in which anxiety and depression have been considered paramount in the ætiology Excessive dependence and

emotional immaturity, extreme sensitivity, inability to cope with real or imagined insults, often verbal, the open expression of anger replaced by a disposition to brooding resentment over periods of weeks, months, or years, are all to be found in these patients, but they are not likely to be uncovered by the methods adopted by Dr Sim and Mr Brooke

I do not understand the importance they attach to which comes first, bleeding or diarrhœa It seems quite irrelevant to the truth or untruth of the psychosomatic concept It probably depends on whether disturbance in mucosal vascularity or motility and secretion predominates, and upon which area of the large gut is mainly affected, and the degree of severity

If, as Dr Sim and Mr Brooke seek to prove, ulcerative colitis is not a psychosomatic disease, how do they account for the accumulating reports, from Holland, U S A , and this country, that psychotherapy is efficacious ?

Ipswich J W PAULLEY

CHRONIC PSYCHONEUROSIS IN GENERAL PRACTICE

SIR,—I enjoyed Dr Watts' readable chatty article in your issue of Aug 16, but I think him unduly pessimistic about the chances of cure One reason for this may be his frequent use of phenobarbitone The barbiturates have an immediate sedative action but this is followed by toxic depressant effects in proportion to the dosage They also render patients less accessible to psychotherapy, particularly re-educational psychotherapy, since they tend to dreaminess and letting the world go by rather than to tackling the causes of basic maladjustments in which the neuroses have their origin

I also think it fatal to give in to a neurotic patient's demand for a placebo A bottle of medicine signifies for him organic, as opposed to neurotic, illness, and an essential step in the treatment of the psychoneurotic is to secure his acceptance of the psychogenic nature of his symptoms—often against strong resistance on his part

Wallasey, Cheshire LENNOX JOHNSTON

COUDÉ STRAIGHTENED OUT

SIR,—In the winter number (vol 4, no 6) of *The Leech*, the journal of the Cardiff Medical Students' Club, there appeared an article on Emile Coudé (1800–70), a surgeon of Niort, France, who, it was alleged, invented, and in 1835 published an account of, the Coudé catheter

This biography was written in a serious and restrained vein, and was replete with two references, one to the autobiography of Emile Coudé, and another to *Le Mois Médical* for a description of the invention In addition, the article contained a reproduction of a woodcut purporting to be a likeness of the inventor

We have been able to prove that the whole of this article is a fabrication, and the references are fictitious To expose this deception is of practical importance As a result of the hoax, a number of pages of the 11th edition of *A Short Practice of Surgery* that were passed for press have had to be reset in so far as the capital C of Coude is concerned, and biographical footnotes to Emile Coude deleted

To save others from falling into this mire, we hope that you will publish this letter The coudé catheter was invented by Louis Mercier (1811–82), the eminent Paris urologist, so well known for his description of the inter-ureteric bar Mercier announced the invention of the coudé catheter in 1836, and of the bi-coudé catheter in 1841 Being translated, coudé (the adjective) means bent, coude (the noun) means elbow

Obituary

KENNETH WELDON GOADBY

K B E , M R C S , L D S , D P H

SIR Kenneth Goadby, who died on Aug 10 at Walton-on-the-Hill at the age of 85, was a bacteriologist who practised his specialty in the borderlands of medicine, and he will be remembered for the resource and vigour with which he applied its techniques to the problems of odontology and industrial medicine

Shell

He was born at Gravesend, the son of the Rev J J Goadby, and was educated at the Grammar School, Henley-on-Thames, and at Reading University He began to study dentistry as an apprentice, but an uncle offered him the opportunity to take a dental qualification, and after a course at Guy's Hospital he qualified in 1896 While he was practising as a dental surgeon he went on to take his medical qualification in 1900 and the D P H a year later He was still a student at Guy's when he met J W Washbourn, who first interested him in bacteriological research, and from 1899 to 1902 Goadby spent part of his time working in Washbourn's laboratory at Guy's In 1903 he was awarded the Tomes prize of the Royal College of Surgeons of England

The following year he was appointed lecturer in bacteriology at the National Dental Hospital, and he continued to hold this appointment after the hospital became the dental department of University College Hospital Here he was drawn into the circle of A V Hill, Barcroft, Dale, Adrian, and Walter Fletcher He was later lecturer in oral hygiene at the London School of Hygiene In 1923 he drew together in his *Diseases of the Gums and Oral Mucous Membrane* what he had over the years learnt and thought about oral bacteriology He interpreted his subject generously, and described not only the diseases of the title but also the effect of mouth conditions on general health, with warnings on the bacterial dangers of whole-scale extractions and on the effect of vitamin deficiency on the jaws and gums of infants In an authoritative section on metallic poisoning of the mouth he drew on his wide experience of industrial toxicology, for he had for many years been one of the Home Office's specialist medical referees for industrial poisoning He sat on departmental committees dealing with the phosphorus rules for match factories and the causes of lead poisoning in industrial processes He was a member of the medical advisory committee of the Ministry of Mines During the 1914–18 war he also served on the War Office committee on tetanus and as honorary bacteriologist for vaccine therapy at the Royal Herbert Hospital, Woolwich For this work he was appointed K B E in 1918

Throughout his life he had always been something of a lone wolf, and after the 1914–18 war he devoted himself to private practice But he remained alert to new problems and new interests Towards the end of his life he was active at the meetings of the Physiological Society and he published in 1949, with his son Dr H K Goadby, a paper on the nervous pathway of the psychogalvanic reflex He held his lectureship at U C H till 1947, and, J L D B recalls,

"He was an ever familiar figure at students' society dinners, where he made a point of speaking to all his colleagues and friends Though we saw little of him in later years, he will always be remembered as an enthusiast in his own subject and a great lover of social functions, where he mixed freely with the students"

He was one of the original members of the medical committee of the Scientific Film Association, which was started in 1942, and later became president of the association R Mac K writes

"Sir Kenneth Goadby gave sterling help in promoting the use of films in medicine and health education As chairman from 1947 to 1952 of the medical committee he gave generously of his time, guiding gently, in a most friendly way the enthusiasm, impetuous at times, of his younger colleagues This was after he retired from his hospital work but he always took in new ideas and put the good ones into action When he resigned as president he was made the first (and only) honorary vice-president of the Association"

He married in 1898 Constance Eva Olding, and leaves one son

JOHN JEFFREYS DENNIS

CB, M.D, M Ch Q U Irel

Surgeon Rear-Admiral Dennis died at his home at Beaconsfield on Aug 4, some months after his 100th birthday

He was the son of Paymaster-in-Chief T R Dennis, R N, and he was educated at Mannamead School, Plymouth He studied medicine in Cork and Dublin, and in 1880 he was one of the last graduates of the Queen's University of Ireland (which in that year became the Royal University of Ireland) In 1881 he joined the Royal Navy as a surgeon, and the following year saw service in Egypt and received "an expression of Their Lordships' satisfaction" for his able performance of his duties In 1892 he was promoted staff surgeon, and he was surgeon of H M S *Turquoise* during operations in the Eastern Sudan in 1884–85, when he was awarded the Egyptian medal and the Khedive's bronze star For the next two years he served with the Naval Brigade and he landed with the Army during the Burma Annexation War He was present at the capture of Mandalay and took part in an expedition to Bhamo

In 1896 he was appointed fleet surgeon, and he again saw active service when he was with H M S *Highflyer* during the naval and military operations in Eastern Somaliland from 1902 to 1903 In the course of his African service he qualified as an interpreter in Swahili In 1907 he was promoted deputy inspector-general and six years later surgeon general During the 1914–18 war he was medical officer in charge of the R N Hospital, Haslar, Gosport, and he was appointed C B in 1916 for his work there. He was placed on the retired list in 1918 He was made a commander of the Ordre de la Couronne Belge in 1919

Notes and News

ON RONGELAP AND AILINGINAE

On March 1, 1954, a thermonuclear device was fired on Bikini atoll in the United States Atomic Energy Commission's Eniwetok Proving Grounds in the Marshall Islands This on-the-ground detonation generated large quantities of radioactive substances, and after the explosion unforeseen wind changes carried these materials in unexpected amounts to inhabited atolls, the nearest of which were Rongelap (about 100 miles distant) and Ailinginae (75 miles) In a lecture at Guy's Hospital last week, Dr Eugene Cronkite, of Brookhaven National Laboratory, New York, described some of the consequences of this accident It is important to realise that this ground burst created a situation which has no close relevance to the question of long-continued worldwide fallout from nuclear weapons fired at a great height

267 persons on four atolls were exposed to this dense local fallout The best estimates of the possible whole-body doses of γ-radiation in air up to the time the atolls were evacuated (between fifty and sixty hours after the explosion) were 175 r on Rongelap and 69 r on Ailinginæ Soft γ- and β-radiation from fallout on the ground and particularly on the skin itself gave a superficial dose high enough to produce skin lesions and epilation These changes were first observed two to three weeks after exposure on skin contaminated by fallout, and the first evidence of damage was increased pigmentation in the form of dark brown to black macules, papules, and raised plaques In about 20% of the people most heavily exposed deeper ulcerating lesions developed, usually on the feet or neck Most of them healed rapidly Regrowth of hair, of normal colour and texture, began about nine weeks after exposure and was complete at six months 23 Japanese fishermen were exposed to the same fallout, and in them the severity and course of the skin lesions seemed to be similar to those observed in the Rongelap Marshallese

Blood changes in those exposed on Rongelap indicated the following course of events [1]

(i) The total white count increased during the first two or more days and then fell below normal The count then fluctuated for some weeks and became stabilised at a low level during the seventh or eighth week About the ninth or tenth week it began to go up again, but complete recovery might take several months or more Neutrophil counts took a parallel course

(ii) The drop in lymphocytes was early and profound and the count may not return to normal for months or years

(iii) The platelet count fell regularly, reaching a minimum on the thirtieth day Some recovery was evident early, but it might not be complete several months after exposure Dr Cronkite said that platelets might drop as low as 25,000 per c.mm before bleeding began as the result of irradiation

The depression of peripheral cellular elements in the blood suggested that exposure on Rongelap was moderately severe, probably within 50 to 100 r of the level where some fatalities would have resulted.

Speaking of the treatment of persons exposed to high doses of total-body γ-radiation, Dr Cronkite observed that transfusion might be more hazardous than radiation The Japanese fishermen had been vigorously transfused, and serum hepatitis might have done some of them more harm than they would otherwise have suffered Only when doses were thought to be in the uniformly lethal range would he advise active treatment, such as transplantation of bone-marrow Otherwise the patient should be observed and conditions treated as they arose

OSTEOPATHY

The origin and development of osteopathy in Great Britain are described in *The Osteopathic Blue Book*,[2] which is claimed to be the first authoritative account of its sort One of the main aims of those who produced this book was to enable the public to differentiate between osteopaths who have been trained as such and those who have not

RISING COSTS AND DIVIDED RESPONSIBILITIES

The development scheme at the Radcliffe Infirmary, Oxford, continues to incur authoritative displeasure At the beginning of this year the Comptroller and Auditor General, criticising it under a transparent veil of anonymity, pointed out that the original estimate of £434,390, made in 1955, had been allowed to grow to £1 million, and that a considerable amount of work had been started "without the Ministry's prior authority"[1] The Ministry of Health, though not defending the methods of the board of governors of the United Oxford Hospitals, have admitted that they are satisfied that the scheme will not cost substantially more than if a more orthodox procedure had been followed But the Committee of Public Accounts[2] now challenge this Ministerial clemency, and firmly state that they have no doubt that "substantial economies could have resulted had the work been properly planned in advance and had the various additions requested during the course of the work been critically examined by the Ministry and the Treasury before being put in hand" The "unenlightened rush" which had taken the place of advance planning and critical examination of the work in process must, in the committee's view, account for part of the increased cost

Putting aside the debatable question as to whether the extra expenditure was avoidable, the committee is concerned that the board should have been able "under extreme pressure by the University" to commit the Ministry to expenditure which had not been approved Though the primary responsibility for these irregularities must rest with the board, the committee tax the Ministry with ineffective supervision which had "considerably weakened Treasury control over the expenditure" They ask for a review of the Ministry's arrangements for financial control of large building projects and suggest that this is especially necessary where responsibility is divided between a board and a university

The Ministry has already recognised the importance of adjusting the balance of financial responsibility between hospital and academic principals, and, with the Treasury and the University Grants Committee, have devised a formula[3] defining in principle what a university's contribution should be towards the cost of a building to be shared with a teaching hospital This formula had not been agreed when the original arrangements for the Oxford scheme were made The University of Oxford's promised contribution to a total which was then £434,390, was £170,500, with a further £31,500 towards equipment The Ministry consider that the part of this contribution (£138,500) allocated to the work that has already been done is not less than the university's contribution should be under the formula, but the proposed contribution towards the remaining work and towards equipment is much less than it would be under the formula The university is unable to find more money, and in the circumstances the Ministry, in consultation with the Treasury and the U G C, have agreed not to seek a further contribution The whole of the expenditure will therefore have to be met from the Vote for the National Health Service and will reduce the amount available for capital expenditure for the service The committee feel that this is an improper use of moneys voted for the health service, and they recommend that in future commitments to provide facilities and equipment which are not strictly an N H S liability should not be made until money is available to meet them from sources other than the Health Service Vote

University of Cambridge

On Aug 2 and 5 the following degrees were conferred

M D—F Ashton, A L T Easton, P M O Massey, George Meachim, •Vishnu Sarma, Leonard Weiss

M B, B Chir—•I F M Buchanan, R C L Feneley, •J G Lancaster

M B—•P J Ball, D A Birkett, •Shirley A Bolt, •E F Brooks, F T Brough, Jan Chippendale, G M Davies, •Nerys Davies, •A J Earl, Audrey E Fairey, A F Fleming, John Hedley-Whyte, N E S Holden, •I D Hunter Craig, R H Johnson N W Oakley, •Allan Reynolds, •Heather M Rumsey, •W G Shakespeare, •Margaret R Skelton, A C Smith, G C Sutton, J C Twomey, H B Valman, D M Whiteford

• By proxy

Royal College of Obstetricians and Gynæcologists

On Friday, Sept 26, at 5 P M at 1, Wimpole Street, London, W 1, Mr V B Green-Armytage will give the Green-Armytage Anglo-American sterility lecture His subject will be recent advances in the surgery of infertility Tickets may be had from the secretary at the college, 58, Queen Anne Street, W 1

Royal Society of Medicine

Anæsthetic section—This section is offering a prize (£30) for the best paper submitted by a senior registrar or registrar holding a clinical appointment in an anæsthetic department or hospital

Fellowship of the society is not necessary for entry The subject will be of the author's choice but must be connected with anæsthesia All papers must be submitted by Jan 1 Further details can be had from the hon secretary of the section, 1, Wimpole Street, London, W 1

British Medical Association

This Association is offering the following essay prizes

A Sir Charles Hastings prize (£75) and a Charles Oliver prize (£50), open to members who are in general practice, a provisionally registered practitioners' prize (£50), and a medical students' prize (£25)

Further particulars may be had from the secretary, B M A House, Tavistock Square, London, W 1

Freud Centenary Fund

The trustees of this Fund are prepared to give financial support to a small number of applicants who have been accepted, or are eligible, for training at the Institute of Psycho-Analysis in London

This support may take the form of a loan (repayable without interest) or of a grant to cover all or part of the training expenses, and the trustees may grant additional funds in cases of exceptional promise All inquiries should be addressed to the hon secretary of the Fund, 20, Maresfield Gardens, N W 3

Darwinism and the Study of Society

To mark the centenary of *The Origin of Species*, a conference on this subject will be held in Adam House, Edinburgh, from April 8 to 10 Further particulars may be had from Dr M P Banton, 39, George Square, Edinburgh, 8

Pneumoconiosis and Byssinosis Benefit Scheme

Widows and other dependants claiming the death benefit of up to £300 provided under this scheme have been given rights of appeal against an unfavourable decision as to the cause of death (S I 1958 no 1240) Up to now the medical decision on a claim for death benefit has been final

Society for the Study of Fertility

The annual conference of this society will be held next year on May 28, 29, 30 in Dublin

On Sunday, Sept 7, at 10 15 A M, at University College Hospital, London, W C 1, Mr G L Bunton will give a clinical demonstration for general practitioners on cases suitable for pædiatric surgery

The *Medical Electronics Center of the Rockefeller* Institute has prepared a *Bibliography on Medical Electronics*, which has been published by the Professional Group on Medical Electronics, Institute of Radio Engineers, 1, East 79th Street, New York 21

A pamphlet entitled Smallpox and Vaccination, which answers in simple language questions that may be asked by the lay public, has been issued by the Research Defence Society, 11, Chandos Street, Cavendish Square, London, W 1 (*6d*, post free)

The St Thomas's Hospital old students' dinner will be held at the Savoy Hotel, London, W C 2, on Friday, Oct 31, at 7 30 P M Prof O L V S De Wesselow will be in the chair Tickets (£2 2*s*) may be had from the hon secretaries at the medical school

CORRIGENDUM "*Calling Dr Kildare*—In the article by Mr H C Elliot and Dr J M A Lenihan (*Lancet*, 1958, i, 1329) the table should have shown under 'Selectacall' the nature of the signal as buzzer, and speech signal when receiver, with speech button pressed, is held to the ear

THE FRONTIERS OF MEDICINE*

C H STUART-HARRIS
M D Lond , F R C P
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF SHEFFIELD

TWENTY-FIVE years ago the newly qualified graduate in medicine was aware of a sense of excitement and of promise in his future medical career He was about to practise in a world engulfed in one of the great periods of change in its history The world was shrinking, distance was being almost annihilated by the aeroplane, and changes were on foot in the lives of continents, such as Asia and Africa, exceeding those in centuries past Since then there have come the doubtful blessing of television, the surge of power from nuclear fission and thermonuclear reactions, and now the earth satellites, which have caught the popular imagination as almost no other achievement has done

All these are the material consequences of the advance of science But what disasters has mankind not brought upon itself in the same period? We have passed through the most devastating of all wars We exist in a world divided into two political and economic systems Every year we witness new pathetic streams of refugees fleeing from political injustice, and we have knowledge of determined efforts at the enslavement of the mind, and of cruelty which has been unparalleled since the Middle Ages We are told that this is an age of violence

While all these vast changes have been taking place, medicine also has undergone a revolution Dr Barry Wood (1952) described the present phase of increase in knowledge as analogous to the logarithmic phase of growth of a bacterial culture We see daily the miracle of chemotherapy and the triumphs of surgery helped enormously by the advances in anæsthesia There have been a steep fall in the infantile death-rate and a corresponding increase in the expectation of life Some diseases have well-nigh disappeared, at least in Britain, and the pattern of others has altered for the better Moreover new drugs have poured forth in ever-increasing numbers, with the result that the doctor can now treat many conditions which he could not previously Those diseases which cannot be cured can often be endured, though at the expense of much medical care and skill

What are the effects of these changes in the structure of medicine on the future practice of our art and science? What will medicine be like in the future for those of you who now stand palpitating on the threshold of your career? Are the next twenty-five years going to be as changeful and as exciting as those which we have just passed through? I cannot claim to be a prophet but I am willing to look with you into the future

To look at the present frontiers of medicine it is necessary first to look backward, because the frontiers of today are not the same as the frontiers of yesterday When I was a student, it was common to feel that patients were admitted to the medical wards to lie and rot The great watch-word was "masterly inactivity", and many were attracted by surgery because of its comparative air of activity and of its desire to thrust forward Yet it is medicine which has undergone the greater change Today the atmosphere of the medical wards has changed We are in the grip of a revolution in therapeutics For the polypharmacy of yore, with its emphasis on mixtures and nostra, has been substituted by a battery of active remedies—antibiotics, antispasmodics, hypotensive drugs, and steroids—so much so that I sometimes feel that it is my job to go round the ward taking patients off, rather than to prescribe, the various medicines which pour into their mouths, their veins, and their buttocks For these new magical remedies differ from the old in one important particular the old remedies were at least inert and did not therefore harm though they did little good, but the new ones are powerful drugs with powerful actions and must be used with discrimination lest the patient suffer rather than benefit

Therapeutics is not, however, the only branch of medicine to undergo a change The investigation of patients has also become increasingly complex Electroencephalography, refined radiological techniques, cardiac catheterisation, tagging with radioactive isotopes, and many other biochemical applications have become routine modes of inquiry Many of these have stemmed from research, particularly from that discipline which we term clinical science and which can broadly be defined as the application of the experimental method to the study of human illness Moreoever there is no sign that we have yet reached the limit of this press and surge of inquiry However disconcerting it may be to those of us who practise the clinical art, the laboratory is firmly established as the partner of the clinician He, poor fellow, must learn to cultivate the chilly discipline of the laboratory bench, because the days of the clinician's flirtation with laboratory techniques are at an end for him If he does not beware, he will have to accept the technician's results without question.

With this increase in the tempo of medicine we sometimes do not wonder at our new powers Particularly is this true for those of you who are growing up with modern medicine and accept the situation without question Let us pause to seek some reasons for this revolution in medicine It is easy to see that the former frontiers of knowledge have often been thrust forwards by the development of new ideas or from a new approach Often this has happened when the barriers to progress appeared impregnable, and yet in an astonishingly small time they have been reduced

Breaking Through the Barrier

Nowadays we are told by press, radio, and television of the great achievements of so-called pure science The phrase has been coined of a "break-through" One even hears it said that the break-through took place on a particular date, a moment of history, when some miracle was first observed in the laboratory Well, why should we not adopt the same expression in medicine? There have certainly been some impressive break-throughs in medicine in the past half-century

One was when Whipple fed his anæmic dogs with liver instead of ordinary meat and noticed that their blood regenerated more rapidly than he expected From such a chance observation came the liver treatment of pernicious anæmia, which in the past twenty-five years has led to the identification of vitamin B_{12} and has banished mortality from pernicious anæmia

Another break-through was when Fleming saw the tell-tale ring of inhibited culture on the crowded agar plate around the focus of fungal growth from a chance spore of

---

* Presidential address to the Sheffield University Medical Society on March 6, 1958.

7044

penicillium which had flown in through the window That break-through took many years to develop Penicillin, when I qualified, was just a laboratory tool to enable one to suppress unwanted bacteria in a culture so that one could obtain a pure growth of an organism not affected by the substance In its impure state penicillin was extremely toxic and so could not be used therapeutically Perhaps, without the genius of Florey and the chemical knowledge of Chain, penicillin would never have been purified, and thus its priceless benefit would have been withheld from mankind But the break-through *was* pressed home A new form of chemical engineering was born to mass-produce the fungal culture and to purify its product to the present crystals, with the results now known to you all

Serendipity

How did these break-throughs happen? Many think that they were the result of a logical sequence of thought and of work Unfortunately the answer both for these discoveries and for others of their kind is that they seem rather to have been the result of an accident or of chance The realisation that chance plays a dominant role in scientific discovery has been much commented on Cannon (1945) has revived the use of an ancient word to describe it The word is "serendipity", which was used by Horace Walpole in 1754 after reading a fairy-tale entitled *The Three Princes of Serendip* (Serendip was an ancient name for Ceylon) The princes (so Walpole wrote) "were always making discoveries, by accident or sagacity, of things which they were not in quest of"

I tried out this word "serendipity" on one of my clever young men, but he got no further than suggesting that it was a name for a new tranquilliser Far from producing serenity of mind, however, serendipity (in the sense in which Cannon uses it) has an effect better described as galvanic Indeed Cannon illustrates serendipity by the experience of Galvani, who first observed that frogs' legs hanging by a copper wire from an iron balustrade twitched when swung by the wind so that they touched the iron From this simple beginning has come the magnificent growth of electricity which now plays so large a part in all our lives

Another example of serendipity was the discovery of insulin, which came from the accidental finding by Von Mehring and Minkowski that the urine from pancreatectomised dogs was attracting a swarm of flies This phenomenon of experimental glycosuria furnished Banting and his student Best with the idea that the pancreas somehow held the key to human diabetes

Then there was Pasteur's finding that fowls inoculated with an old culture of bacteria causing chicken cholera became ill but did not die, whereas fresh cultures of the same organisms were extremely virulent and caused fatal disease This led him to work on the deliberate attenuation of cultures so as to obtain an avirulent culture or vaccine which could protect against the actual disease Then came the classical experiments on vaccination of sheep against anthrax and Pasteur's work on rabies Pasteur described serendipity in the words "chance favours the prepared mind" Thus many may witness the phenomenon, but only those with the ability to grasp its meaning understand what they see

Of course, it would be foolish to overlook the fact that much scientific research consists of hard slogging on a planned basis in which chance plays very little part, but we have to draw a distinction between research and discovery The first step towards a real discovery may have been taken either as a result of intuition based on observation or because of an experiment which was planned answer one question but showed something else Jenn is said to have been startled into work on smallpox by th remark of a pretty milkmaid that she would never ta smallpox because she had had cowpox Perhaps, howev Jenner would never have been successful in his work b for John Hunter's advice "Don't *think*, try"

In virus work it has been the advice to try which seen to have yielded discoveries, but pure chance has al played a role at times When Wilson Smith, who lat became professor of bacteriology in Sheffield and now University College Hospital, had exhausted the vario animal species available for experimental work o influenza in 1932, it was Douglas who said "Why n try a ferret?" Thus it was found that the ferret wa susceptible to influenza virus, and this discovery opene up a huge new field in virology Contrast this with th story of Richard Shope, who injected some of his favouri laboratory animals, pigs, with swine-influenza bacilli ju before going away for a holiday A few days later h received a telegram from his technician "Hogs hav swine 'flu" This ended his holiday but began the wor on the strange story of the earthworm reservoir o pig-influenza virus

Again the result of "trying the impossible" ha brought a rich reward in work on polio John Enders an his team at the Boston Children's Hospital in 194 attempted the impossible by inoculating some poliovir into test-tube cultures of human fibroblasts Poliomyeli virus was so highly specific for the nervous system, sai the pundits, that it would grow in none but the mos highly differentiated of all mammalian cells—the nerve cell—and here were our experimenters casually implantin it into the lowliest of all cells—the fibroblast, which grow like a weed in the garden of a tissue-culture and outstrip and chokes the growth of other cells The fibroblasts thu inoculated succumbed to the virus—they withered and died Poliovirus had been grown in a test-tube and in a quantity far exceeding that previously found in the inoculated monkey This discovery opened the door to much further work on the best tissue-culture cells to use for the preparation of a human vaccine When monkey renal epithelial cells were chosen as the best available medium, Salk applied himself to the inactivation of the virus in the culture and eventually selected formalin as the most appropriate chemical for killing the virus and thereby rendering the vaccine safe

The Follow-through of Enders' Discovery

The story of the Salk vaccine has been told by many people in many different journals It is an astonishing story of success and disaster It is compounded of a mixture of courage, audacity, timidity, and sheer bungling The trials of the vaccine held in the U S A in 1954 exemplified the best tradition of impeccable scientific investigation It was the largest vaccine trial in history Nothing which has happened since 1955 should detract from the greatness of the American achievement For one thing, it required extreme courage to carry out this first trial The child is glorified in America as the most precious form of life I do not believe that Americans are more willing to allow their children to be the subjects of an experiment than we are Yet the child *had* to be the guineapig in this trial of protection, and Americans did not shrink from allowing their children to be inoculated, and they were also willing to allow some of them to act as controls and to be inoculated with a fluid containing

, at all The result justified their faith in their s, and the Salk vaccine was proved to be effective came the Cutter disaster, when certain batches of containing residual live virus caused poliomyelitis . of those who were inoculated and even in their contacts The Cutter disaster was not due to tence on the part of the manufacturers Rather n illustration of the old adage " more haste, less

Had more time been devoted to the methods of the vaccine for live virus and to a proper system of checking the safety tests themselves, it might not ppened At any rate, we in this country felt the tional impact of the disaster, so the British vaccine dified to increase the factors of safety This could eant that our vaccine, though safe, had been robbed tivity, and thus came the need to test its protection trolled trial was thought possible in Britain, but we cceed in measuring the effects of the first few d litres of British vaccine Because there was not vaccine available for all the children whose parents ered, a random selection of the children to be ted was arranged according to their date of birth who were uninoculated furnished a control group subsequent experience of poliomyelitis was the ound to that of the inoculated children The result l that the British vaccine was at least as protective ish children as was the Salk vaccine in the U S A al Research Council 1957)

cannot yet tell how successful the introduction of ccine against poliomyelitis will be in enabling us to l the disease The indications from Denmark, lia, Canada, and the U S A are that it will reduce ssively the yearly attack on our young children. ately we may succeed in banishing poliomyelitis as diphtheria has been banished Imagine the ations of this on the work of doctors in infectious-e hospitals, our colleagues in orthopædics, the therapists, and all those now concerned in com- g poliomyelitis

Medicine and Society

oking back on the past few years I am chiefly ssed by the way in which the trials showed the ged relation between people and doctors In the A poliomyelitis has been a much greater scourge in Britain, its people have contributed millions of s to aid research, and at times it has been the energy he effort of lay people which have created the condi- for an advance in knowledge At times also the rs must have felt as though they were being forced ctivity by a public pressure and conscience which did not share Even in Britain, where poliomyelitis een much less of a menace, the research on the ne has roused much public interest In many other also public interest has grown to the extent that we have to maintain good public relations if only to e that we have the right conditions for our work sometimes means that the scientist has to endure dragged out of his quiet laboratory to provide ers to questions of public interest There has to be k a nice balance between educating the public and g false hopes or fears Some, including many ent doctors, feel that it is not part of the profession's nsibility to educate the public. They go on the iple that " a little learning is a dangerous thing ", that it is far better for people not to know anything t disease or about the symptoms of illness than just a smattering I think this view ignores an important aspect of the times in which we live, which has resulted from the growth of the communication of ideas

Sir Francis Fraser (1958) emphasises that one great consequence arising from the advances in science and technology is our increased ability to communicate with each other Events in distant lands are photographed and viewed in our own homes within a matter of hours We are no longer restricted in our interests to what goes on in our family or social group As a result there is a growing interest in and demand for information on all aspects of our life, including illness Doctors can no longer stand aside and maintain the attitude that it will do no good for the public to know The public *wants* to know, whether it is good for it or not, and it is our new responsibility to provide information which is correct This revolution in the public relations of medicine will certainly affect you in whatever sphere you practise medicine Unless you practise in a mentally defective community, your patients will know more and ask more questions than at any previous phase of our history Your answers will demand great wisdom if the public is not to be turned into a mass of hypochondriacal neurotics

This brings me to the future role of doctors Side by side with the great advances in the technical achievements of our craft we witness a remarkable increase in the public demand for medical care The death-rates go down, but the volume of medical work is steadily increasing Fry (1957), a general practitioner at Beckenham, says that he sees 90% of the patients on his list on one or more occasions in a period of five years Logan and Brooke (1958) find that, at any age and in any month, at least 50% of adults complain of an illness of some kind or another Are these people ill with physical ailments or with neuroses ? The doctors of the Sheffield University Health Service see half of all the students who elect to draw on the University's organisation every year Are students really in need of medical care to this extent ?

One reason for this rising demand to see the doctor is that the many minor ills which befall us all are no longer regarded as inevitable consequences of being alive We all desire not simply life but abundant life, not an absence of disease but a feeling of mental and physical fitness Modern life, with its struggle for existence, its frustration, and its unhappiness, imposes a strain which is too great for the unaided citizen The doctor has become a symbol of society's need for support and consolation Nor is there any sign that this is a temporary phase Modern man, for all his technology, is a frightened creature as much in need of guidance and more in need of faith than his forefathers He is likely to become increasingly dependent on medicine as knowledge advances

Future Conquests

What new Everests of knowledge are there for *you* to scale ? Some diseases have disappeared or are diminishing We can expect, for instance, that diseases such as tuberculosis, now being attacked both prophylactically and therapeutically, will slowly disappear New diseases are appearing—e g , the disorders of the nervous system probably caused by viruses such as the Royal Free disease and aseptic meningitis with a rash New industrial processes—e.g , the use of beryllium for fluorescent strip lights—bring us new hazards A new branch of medicine is growing up to cope with the complexities of the nuclear age, for radiation hazards now exist for the population as a whole and not just for radiologists What new menace exists for man in his attack on outer space can only be surmised But the perils which are endured by Dr Quatermass in his various experiments and which we pass over as the burblings of science fiction may perhaps be taken more seriously if we reflect on the earlier prophecies of Jules Verne and H G Wells The science fiction of one era has been described as the scientific literature of the next So you who will practise medicine twenty years from now may deal with disorders undreamt of today New frontiers will have sprung up as a consequence of man's struggle with his environment

I wonder if you will have learnt the conquest of less romantic evils Will you have taught mankind to prevent cancer of the lung by smoking fewer cigarettes, or will you have rendered the precious weed harmless by removing the carcinogen? I suspect the latter, but I hope you will be more successful in your general task of teaching man to control his habits than we of my generation have been Perhaps at least you will have begun to control disorders such as arteriosclerosis and bronchitis, which may be due in part to our faulty ways of living But will you have found the answer to the riddles of cancer and of the chemotherapy of virus diseases? These subjects appear ripe for the major break-through, perhaps from some entirely unexpected direction Nucleic-acid chemistry is advancing so fast that one wonders about its impact on genetics and on hereditary disease Will you in your lifetime be able to repair the chemical faults underlying so many hereditary conditions? At any rate one can expect an expansion of the frontier which so tightly hems in our power to deal with mental illness Psychiatry has far too long been the Cinderella of medicine, and the next twenty-five years will surely see a revolution here

Finally, may I hope that you will have learnt how to assess the results of your efforts? It is only since the use of clinical trials that we have begun to debunk medicine of much that is false The principle could profitably be extended to include much more than an assessment of a drug or a vaccine The results of surgery and of psychiatric therapy are fit subjects for exploration We must grow in candour as well as in technology

My last remark must be to remind you of the words of the writer of Ecclesiastes (9, 11) which seem a fitting comment on this address

"*The race is not to the swift, nor the battle to the strong, neither yet bread to the wise, nor yet riches to men of understanding, nor yet favour to men of skill, but time and chance happeneth to them all*"

" We live in a scatterbrained age of distractions Suspended by vague but painful ambition, prodded by anxiety, and baffled by frustration we lose the capacity for sharp and exclusive focus of the attention Attention can be cultivated Don't try several things at once, but whatever you do, take it all in Can you quote a poem exactly, or even the title? The near miss is about as helpful as the telephone number with only one wrong digit Specification, precision, exactness come only with sharp and complete attention "—Prof WILLIAM B BEAN, *The Pharos*, February, 1956, p 13

A NEW MEDICAL CURRICULUM

D C SINCLAIR
M A Oxon , M D St. And
PROFESSOR OF ANATOMY, UNIVERSITY OF WESTERN AUSTRALIA

GRUMBLING at institutions is an ancient sport, and in British medical schools the curriculum is the traditional target for abuse Like the Walrus and the Carpenter, most medical teachers weep like anything to see such quantities of unsatisfactory material "if this were only cleared away", they say, "it *would* be grand" Unfortunately it is not very easy to clear away established curricula which have been moulded by years of gradual evolution Just as nothing is more permanent than a temporary building, curricular material may obstinately persist long after it has outlived its usefulness

Until last year there has also been another hindrance to reform of the curriculum, for the General Medical Council made detailed "recommendations" to the medical schools, specifying a virtually stereotyped course of instruction If the prescription was faithfully followed recognition of the schools was automatic, if not, the issue was clouded with doubt In the circumstances few medical schools felt bold enough to adventure very far away from the well-beaten path

But in 1957 the Council decided that an undiluted and universal orthodoxy might not be a wholly good thing, and, by suppressing the details which used to surround its recommendations, left the way clear for experiments By pure chance it was also in 1957 that the newest medical school in the British Commonwealth opened its doors to medical students Those who had to frame the medical curriculum in the University of Western Australia were thus given a relatively free hand, the bonds of official regulation had just been loosened, and there was no need to dismantle an existing curriculum the components of which had become rusted in position

It is of course true that even in such a promising combination of circumstances it is impossible to plan a curriculum without making concessions to the realities of the local situation The ideal is unattainable, and indeed exists only in the abstract The world is too much with us, late and soon Nevertheless, it may be of interest to examine what has so far been done in Western Australia, and in order to understand the features of the new programme it is necessary to make a brief review of its background

The Background

The University of Western Australia was founded in 1912, and has grown, at first steadily and recently very rapidly, until in 1958 it accepted 2629 matriculated students, including 82 who wished to study medicine The minimum age for entry to any faculty is 17, and, as in other Australian universities, any student capable of matriculating is accepted for tuition in the faculty of his choice For a long time those who wished to become doctors have been able to take the subjects appropriate to the first year of a medical course in Western Australia, but their subsequent instruction has depended on the sympathetic hospitality of other universities—notably the University of Adelaide The increase in population, which has affected Western Australia along with the rest of the Commonwealth, made it more than ever desirable that the State should produce its own doctors, and at the same time the pressure of local applications made it impossible for Adelaide to continue accepting Western Australian students In 1955 an advisory committee suggested that the needs of the State would be met by a medical school with an annual output of 40 graduates (this estimate may require modification later, in the light of future immigration figures) A public appeal was launched for funds, and achieved the astonishing sum of £A570,000 The State Government contributed an additional amount of £A150,000, and undertook to pay the annual costs of the school

The staffing of the new school involved the establishment of nine new professorial chairs within the university All these—anatomy, physiology, biochemistry, pathology, microbiology, medicine, surgery, obstetrics and gynæcology, child health—are now filled, and most of the corresponding junior appointments have also been made The professors of pathology and microbiology are responsible for the corresponding hospital service departments, and the clinical chairs are whole-time appointments, though private consultation work is permitted up to a stipulated maximum each year The preclinical professors have responsibilities in several faculties other than medicine—for example, the department of biochemistry teaches in the faculties of science, dental science, and agriculture, and the department of anatomy is currently dealing with students in the faculties of science, dental science, arts, and education

Eventually it is hoped to establish a medical centre based on a new hospital to be erected close to the university, this is a long-term development, and for the time being the preclinical departments are to be found on the main university site, some four miles from the clinical departments, which are based on the Royal Perth Hospital Teaching in child health and in obstetrics and gynæcology is centred on hospitals about two miles from the main clinical school.

The pattern of medical care in Western Australia is such that relatively few patients are available for teaching purposes, and in any case the Royal Perth Hospital was not constructed as a teaching hospital In consequence there is a limit to the number of students who can be taught from the third year onwards, and this limit is at present set at 48 students in each year The preclinical departments have more accommodation, but, because of their other commitments and their limited staff, only 60 students can be admitted to the second year of the course

By the time the details of the planning came to be considered teaching had already begun at both ends of the curriculum The first students to be dealt with were 16 final-year students who in 1957 returned from Adelaide to finish their course in Perth (and to obtain Adelaide degrees) In 1958 another batch, this time of both final-year and fifth-year students, returned from Adelaide and in addition 60 second-year students began work in the preclinical departments The first Western Australian medical degree will be awarded by the faculty in 1959, but the first students to complete the entire course in Western Australia will not graduate until 1962.

General Planning

This short statement has outlined many of the features of the local situation to which the curriculum had to be adapted For example, complete integration of teaching in the manner of Western Reserve was at once ruled out because the small staffs of the preclinical departments have to meet considerable teaching demands from other faculties, and because the components of the school are geographically dispersed A "self-service" curriculum in the Oxford manner, under the control of tutors, was excluded because of the lack of adequate staff and because of the relative immaturity of the students, most of whom come from schools where there is no equivalent of the British sixth form Any drastic reorientation of the clinical work was initially impossible because of the need to receive back into the fold the Adelaide students who had had an orthodox beginning to their education Examinations could not be held to the minimum demanded by the General Medical Council because of the unrestricted entry to the course, which made it necessary to use the first and second years of the course as a means of student selection And so on, enough has been said to indicate the type of consideration which had to be imposed on the generalised "ideal" curriculum which might possibly have shaped itself in the minds of the faculty

In addition to these local factors, two principles of more general applicability were kept in mind during the planning stage One of these was the value of liaison between the various departments A series of weekly lunch-time meetings was instituted among the professors, and it is proposed to continue this most valuable practice indefinitely Frequent contact and discussion of problems have made it difficult for any department to feel that it has been isolated or unjustly treated, and the sense of cooperation in an important enterprise has not been allowed to die out Each department has gained a most valuable insight into the needs and difficulties of the others, and in this way is undergoing an education which must eventually render it more capable of attempting to educate others

The second principle was that the details of time-table arrangements or teaching methods must never obscure the all-important attitudes of both teachers and taught towards the process of becoming a doctor The human aspect of the curriculum was kept well in front of its mechanical tricks Nevertheless careful consideration was given to the most recent developments in teaching and in curricular reorganisation, and an attempt was made to put into practice the features of these which were best suited to local conditions, although it was fully recognised that what was new and experimental was not necessarily better than that which was old and familiar The details of planning were deliberately kept as flexible as possible, so that modifications could be introduced with little disturbances as they become desirable

Two ideas current in modern medical education were unreservedly accepted by the faculty the first of these was the desirability of allowing the student time to think for himself, and the second was the value of coordination

It was decided that the best way of accomplishing the first objective was to cut down the load of formal lectures as much as possible Part of the time so released has been given over to teaching of the tutorial or seminar type, but most of it has been allotted to the student to use according to his needs In the second and succeeding years of the curriculum one whole day in each week (apart from Saturdays and Sundays) has been left free from organised classes This is naturally strong meat for many students, who have been accustomed at school to have predigested information thrust at them from morning to night, and feel ill-nourished without a steady supply of this homogenised material Accordingly, in the earlier stages of the curriculum "free time" is not quite so free as it is later on, when the student has developed some sort of judgment of his own In the second year, for example, demonstrations, films and talks relating to the subjects being studied are provided These sessions are not compulsory, but are intended to indicate to the student some of the lines along which he could profitably direct his mind Later in the curriculum the students are encouraged to organise for themselves talks from people outside their immediate horizon—a pastoralist, a brewer, an actor, and so on—the idea being to broaden the notoriously limited outlook of a clinical medical student Interspersed with these talks are discussions, some of which are led by members of the department of psychology, and deal with matters such as hypnotism, race and class prejudice, learning theory, and telepathy Students may use their free time to undertake a piece of field work in social medicine, or to visit the families to whom they will be attached as part of their social medicine training

Not only has the student been given time to think, he is actively encouraged to go through this unfamiliar exercise at every possible opportunity For example, many of the practical classes throughout the curriculum have been organised to avoid, so far as possible, the cookery-book atmosphere engendered by following a standard recipe stolidly through to " success " or " failure " Instead, the student is asked to explore the reasons behind the form of the experiments he undertakes, and is asked questions about them which have answers to be found only in his own work and not in any textbook

The concept of coordination between departments has been put into operation at three different stages in the curriculum, and the individual features of these coordinated courses will be described later The first is designed to prevent fragmentation of the preclinical study of human biology into artificially bounded departmental " subjects ", the second aims to bridge the geographical and psychological gap between preclinical work and the study of patients, and the third is an attempt to show how various clinical and preclinical disciplines can cooperate in the solution of problems of preventive and social medicine

There are six years in the medical course In the first two of these the academic terms are of the standard university length—two of nine weeks and one of eight weeks In the third year the first and third medical terms are twelve weeks long, and the second term will correspond to the standard university term, by this means medical students will have the same holiday as the other students, and may thus preserve their connection with university sport and other general university matters as long as possible From the fourth year onwards, however, all the three terms are twelve weeks long and the students move their headquarters to the hospitals

The Curriculum

FIRST YEAR

The cardinal features of the first year are that entry to it is unrestricted, provided the matriculation requirements are satisfied, and that there is at present no exemption from first-year subjects on the basis of subjects studied at school This latter situation may alter in the near future since a number of schools hope to establish something like the British system of " sixth-form " teaching At present the quality of instruction in different schools is so diverse that the university insists on a uniform first year and furthermore regards any attempt to preselect students before entry to this first year as impracticable It follows that the 82 students in the first year feel themselves to be under considerable pressure, for at the end of the year they face a selective examination which must necessarily reduce their number to 60, since this is the maximum the second year can accommodate The first year is thus competitive, and the student tends to regard it as an extension of the school system in which accumulation of examination material is of paramount importance

The first-year subjects are physics, chemistry, and general biology The physics and chemistry are special classes designed for students of medicine, dental science, and agriculture The biology class is not yet in operation, and students are at present taking first-year zoology and a special course in botany for medical students When staff becomes available to give the general biology course, the general and functional aspects of the subject will be emphasised and little purely morphological or taxonomic material will be included The establishment of a combined biology course in place of botany and zoology will leave time for the student to take a fourth subject in his first year, and whether this is desirable or not is still under consideration If a fourth subject is taken, it may well be one which has little immediate connection with medicine It has been suggested, for example, that a special course might be given by the faculty of arts, including the elements of such subjects as logic, philosophy, and English Whatever the precise nature of the first-year course, the main difficulty, so long as there is no preselection, will remain that of inducing the student to alter his opinion that the subjects studied are merely a device for awarding or withholding marks

SECOND YEAR

Much of this attitude persists into the second year, and here too, little can be done about it so long as students are faced by selection at the end of the year It is one thing to know that the normal wastage in the second year may be as much as 20%, and quite another to be told that the wastage *must* reach this figure because accommodation in the third year is limited to 48 places It is probable, therefore, that the attitude of the students will continue (with few exceptions) to be unsatisfactory until they reach their third year at the age of 19

In the second year the student takes a coordinated course in human biology given by the departments of anatomy and physiology The departments function separately, but there is provision for interchange of staff in relation to specific topics, and anatomy teaches some function while physiology teaches some structure Other teachers are occasionally involved, for example, the instruction in hæmatology is supervised by a member of the pathology staff The course covers the main features of the various bodily systems and tissues, and in each the account of the gross and microscopic anatomy precedes the account of function

This course in human biology is coordinated as closely as possible with the instruction in topographical anatomy which begins in the second year In the first term the student dissects the upper limb while the structure and function of the nervous and locomotor systems are being discussed in the biology lectures In the second term he dissects the brain and the thorax during the discussions of the cardiovascular and respiratory systems In the third term the dissection of the abdomen accompanies the study of the digestive, excretory, and endocrine systems It is clearly impossible to organise a complete integration of regional dissection with systematic lectures, but it seems reasonable to try to avoid the usual dissociation which occurs in the student's mind between the lifeless and uninspiring vista he sees in the dissecting room and the functional aspects of his own and other living bodies

Also in the second year is an elementary course in biochemistry It has so far proved difficult to associate this very intimately with the human biology course, because the instruction the biochemistry course contains has to serve the needs of science and agriculture as well as of dental and medical students

At the end of the year the student is passed or failed on the basis of his performance in written examinations, together with a consideration of his practical work throughout the year, as assessed by class examinations, his practical notebooks, and his general performance in practical work The major feature of the written examinations is a paper in which every question demands a knowledge of the relevant anatomy, physiology, and biochemistry Each question in this paper will be marked by two examiners, consulting with the third where necessary

The object is to discourage the student from breaking down the coordinated course into its components again by working for examinations in which the "subjects" are artificially separated. Assessment at this stage has the force of a selection device, and the method adopted is an attempt to ensure that students who are capable of synthesising information are given preference over those who are not. Selection at the end of the second year instead of at the end of the third means that students will be rejected at a time and at an age when they have not yet committed themselves irrevocably to medicine as a career.

In the second year there is a class examination in topographical anatomy, and the "viva" system is in force in the dissecting-room, but promotion to the third year does not depend on topographical skill. Nevertheless, the results of the class and oral examinations count heavily (40%) towards the pass or fail assessment in topographical anatomy, which comes at the end of the second term of the third year.

THIRD YEAR

In the third year most of the process of selection is over—the class is now down to 48 in strength, and further reduction is not necessary, though some normal wastage must inevitably occur. Accordingly it is possible to inculcate a broader attitude of mind in the more receptive students, and to encourage them to think of their studies as a preparation for the practice of medicine rather than a set amount of work to be got through for an examination.

Topographical anatomy continues formally throughout the first two terms, in the first the student dissects the head and neck and is given a course of lectures and demonstrations in general and regional embryology. In the second term he dissects the leg and revises for the professional examination at the end of this term.

Third-year physiology and biochemistry persist throughout all three terms, but in the second term there begins the second of the three coordinated courses in the curriculum. On one day in each week of this term the student visits the hospital. Half the day is spent in studying general pathology, and in the other half he is given, in the atmosphere of the hospital, a talk by a preclinical teacher on some specific biological topic. After this the students will break up into small groups supervised by clinical teachers to see how the applications of the problem discussed work out when observed in hospital patients. For instance, a physiologist might give a talk on the formation of tissue fluid and the possible disturbances of this process, and the student would then be introduced to a patient with œdema. Or an anatomist might discuss the results of section of a peripheral nerve, and the student would then meet a patient with a recovering nerve injury and learn something of his experiences and disabilities.

In the third term of the year three days a week are spent in this way, and instruction in the principles of microbiology and immunity is added. The overlap between pathology and physiology is stressed by both departments, and an attempt is made to show how pathology follows naturally on from anatomy, physiology, and biochemistry. Though formal anatomy has stopped, the importance of anatomy as a sound basis for clinical work is stressed throughout the rest of the curriculum. In the third-term coordinated course, anatomy combines with the departments of child health and psychology to indicate the importance of a knowledge of the processes of physical and mental growth during childhood. At this time also the physiological aspects of menstruation, pregnancy, parturition, and lactation are discussed by the departments of obstetrics and gynæcology. Each student witnesses a normal delivery, and will follow the subsequent history of the child in its home environment as an exercise in social medicine.

During the second and third terms of the third year the student receives the greater part of his instruction in psychology, in the form of a series of lectures and demonstrations. The department of psychology also participates, however, in the fifth-year teaching, in relation to pædiatrics, and again in the social medicine course.

At the end of the third year there will be the professional examination in biochemistry, and also a coordinated examination in physiology and the principles of pathology in which a question on psychology will be asked. Here again the questions will be designed to make the student synthesise rather than fragment his knowledge.

FOURTH YEAR

From the fourth year onwards the students are based on the Royal Perth Hospital, but their connection with the preclinical departments is not wholly severed, for the paraclinical and clinical teachers insist on the importance of an adequate knowledge of the basic sciences. Preclinical teachers may be called upon to participate in seminars or conferences, or to give occasional lectures.

In the fourth year instruction in pathology and microbiology continues. The microbiology class has now a more professional bias, and deals with clinical microbiology and virology; clinico-microbiological conferences are introduced. At the same time pathology becomes systematic, and the student begins to attend necropsies and clinicopathological conferences. These conferences persist weekly throughout his entire clinical education. At the end of the first term the course in microbiology is completed, but the pathology course continues to the end of the second term, during which it contains instruction in clinical biochemistry. At the end of this term occurs the professional examination in pathology and microbiology. In the fourth year also comes the instruction in genetics—a short course of half a dozen lectures relating to the fundamental principles of the subject and illustrated where possible by reference to human disease.

This year also sees the beginning of the student's clinical work proper, and it is now that he does his clerkships in medicine and surgery, six months in each. Three months of each clerkship is spent in the professorial units and the other three months in one of the "firms" directed by other senior clinicians. The formal teaching in medicine and surgery is spread throughout the year, and, so far as practicable, is coordinated with the data presented in the courses in pathology and microbiology. The very nature of the material available unfortunately prevents this coordination from being anything like perfect. The general scheme of clinical work is that in the fourth year, during the period of didactic instruction, students should be as closely associated with the professorial units as possible. In the fifth year they will spread out to study various other disciplines which are either subsidiary or else based on other hospitals, and in the sixth year they return to their main base to consolidate and synthesise their knowledge and experience.

FIFTH YEAR

In the fifth year the student has his formal teaching in obstetrics and gynæcology, pædiatrics, and psychiatry, the lectures and demonstrations in these subjects are spread throughout the year For clinical clerkships the year is split up into three periods of four months, one of these periods is allotted to obstetrics and gynæcology, and one to pædiatrics The clerkship in obstetrics is a resident one occupying two months, and the student will deliver approximately twenty patients In the third four-month period the students study different specialties, such as anæsthetics, orthopædics, otology, and ophthalmology In the course in pædiatrics the emotional problems of growing children will be emphasised with the help of the department of psychology, and in the gynæcology course there will be a series of lecture-demonstrations given by the pathology department

Throughout the year occurs the third coordinated course in the curriculum This course in social medicine takes the form of a series of symposia and discussions, together with practical work organised by the clinical departments in conjunction with the staff of the State Public Health Department, the department of psychology, and others The scope of these classes is wide, and includes such matters as nutrition, vital statistics, delinquency, epidemiology, and the causes and prevention of accidents

At the end of the fifth year there are examinations in the minor specialties These examinations are oral only, and it is represented to the student that the stress laid upon them is of a different order from that attached to the final examinations at the end of the sixth year

SIXTH YEAR

In the sixth year the student returns to his base in the Royal Perth Hospital, and spends the year relatively free from formal classes Instead, he revises and extends his existing knowledge by attending ward rounds, tutorial classes, outpatients, clinicopathological conferences, and other entertainments of his own choosing He also participates in "grand rounds" run on the American pattern by the students under guidance from their clinical teachers

At the end of the year the student faces the qualifying examinations in medicine, surgery, and obstetrics and gynæcology The interpretation of these "subjects" is a catholic one, and there is no hesitation about including questions which demand a knowledge of disciplines other than the one under consideration Thus, a question on the thyroid gland given in the "surgery" paper might expect a demonstration of the candidate's grip on the physiology, biochemistry, and medical treatment of thyroid intoxication, in addition to the pathology and surgical treatment of the condition Similarly, the fact that a given patient is examined by a candidate under the heading of "clinical medicine" does not absolve him from discussing the surgical potentialities of an enlarged group of lymph-nodes There are written, oral, and clinical tests of the candidate's knowledge, and at this stage the presence of external examiners, desirable throughout the course, is regarded as absolutely essential The isolation of Perth makes the problem of supplying and paying for external examiners a very bad one, but it is hoped to obtain examiners from the Australasian area every year, and that they will be regularly supplemented at intervals by examiners from Britain and America

There has been no mention of the subject of pharmacology in the above outline, this is because its place in the curriculum is still uncertain No appointment in pharmacology has yet been made, and it is naturally felt desirable to wait until a pharmacologist arrives before fixing the definitive position and scope of his subject Nevertheless, it is probable that pharmacology will be treated as arising directly from physiology, and indeed the practical work in pharmacology will initially be done in the laboratories of the department of physiology Most of the formal pharmacology will occur in the fourth year, and instruction in the clinical and therapeutic aspects of the subject will be given throughout the later stages of the curriculum whenever the question of treatment arises naturally out of the clinical discussions

Statistics has been given no formal place in the curriculum, but this is not because it is thought unimportant Instead, it has been agreed that each department shall add its quota to the student's knowledge as he passes through it Anatomy, for example, deals with the question of biological variation, the normal distribution, and the meaning of standard deviations Physiology adds to this the methods of comparing means and the assessment of the significance of their differences, in pharmacology the statistical basis of clinical trials and other methods of evaluating the actions of drugs will be discussed, and so on

Discussion

A curriculum such as this is naturally tentative as regards its details As the faculty enlarges, more and more may become possible in the way of individual attention, coordination, and possibly integration At the same time university policy in relation to preselection may alter, making it possible to deal with the students in the early stages rather differently In the future a medical centre may be established, in which case liaison between departments could become closer still It is only by working a system such as the one proposed that its defects and advantages can be assessed, and great care has been taken to avoid any suggestion of finality For the next few years a considerable amount of discussion will naturally take place on the desirability of making alterations, but with every succeeding year these alterations will become less and less easy, and it is intended to lose no time in making any revisions which may prove to be needed

But whatever changes in detail may occur, it is unlikely that the basic principles on which the planning has been founded will alter The importance of looking on teaching and being taught as a cooperative endeavour will continue to overshadow the niceties of curricular organisation, and the education of the faculty by acquaintance with the problems of others will persist as a cornerstone of the future of teaching in Western Australia

This paper necessarily represents a personal view of the curriculum, seen through the eyes of one who participated in its design If one of my colleagues had written it there would no doubt have been changes in emphasis Nevertheless the framing of the curriculum has been in a very real sense a joint enterprise, and what is set out in this article has been agreed to by all It may be that some interest attaches to the names of the new professors in the medical school They are

THE BOTTOM OF THE LADDER

HOW TO BE HAPPY THOUGH RESIDENT

W BRYAN JENNETT
M B Lpool, F R C S
LECTURER IN NEUROSURGERY IN THE UNIVERSITY OF MANCHESTER

> " Content may dwell in all stations To be low,
> but above contempt, may be high enough to be happy "
> SIR THOMAS BROWNE (1643) *Religio Medici*

ALL must be residents now Not only those who essay to scale the Moran ladder, or those who choose to extend their clinical education But also those who are anxious, and feel ready, to enter general practice, and those who know they have not a vocation for clinical medicine and are naturally restless to begin one of many valuable careers in the non-clinical field All these must enjoy or endure a year of hospital life They will have a more pleasant and profitable year if they think a little about it in advance

Another Gap in the Curriculum ?

It is accepted that much of the art of medicine can only be taught by precept and example This is too often the excuse for failing to offer any advice at all about matters which are equally difficult to teach by example as didactically Who is to be the example for the dozen or so newly-qualified residents who take up their posts in a hospital on the same day ? Little can be learnt from a visiting consultant about how to survive in a complex closed community twenty-four hours a day for a year Virtually no consultant has been a resident under the National Health Service, and most do not appreciate the extent of the change as it affects the lower orders The neophyte may well be regaled with accounts of bygone days when pay was a pittance and discipline harsh, when the resident had to write letters to the doctors by hand and generally had to do much that today falls to the ancillary staff—and the implication is that the increasing number of ancillaries has eased the life of the hospital resident

It is, however, the very complexity of the staff of the modern hospital that makes the resident's task rather different and perhaps more difficult than previously Departments which previously consisted of one person who could be won as an ally now carry a staff with a hierarchy of its own, competing both within itself and with other departments for prestige and power Radiology, pathology, and physical medicine carry several doctors on their staff, and almoners, secretaries, and records clerks have multiplied and thrown up their own chiefs of department ready to do battle with anyone infringing their unwritten rules " 'That's not a regular rule you invented it just now,' said Alice " All these, in addition to the more familiar triad of patients, nurses, and medical chief, have to be reckoned with by the resident today

Administrator

Administration has been described as an *enabling* process (Taylor 1952) Residents enable the staff of a hospital to work together for the good of the patients, the resident is the only person with all the facts at his disposal —he is the final common path to the patient He is the doctor who sees most of the patient and his relations He sees the ward sister not only on the formal round but also in the evening when the others have gone, when he may hear much about his ward that never comes to the notice of his senior colleagues It is his privilege to accompany his chief all over the hospital and to observe him dealing with patients and colleagues It is he who will talk to the family doctor late at night about a worrying case And so on

If the resident is not prepared to accept the delicate task of liaison officer between all these different persons, and to regard the smooth integration of all their various wishes and demands as his most important task, it will be a pity for everyone and not least for the patients The resident may protest that he came into hospital to enlarge his clinical experience and not to be an administrator He probably thinks of clinical experience as an extension of his final year as a student—seeing and examining as many patients as possible, eliciting signs with greater assurance, and perhaps learning a few techniques If he tries to do just this and neglects his rightful duties, he will learn little of doctoring and may well become one of those sad misfits—the doctor who doesn't get on with people and therefore can never get on with good doctoring If, however, he accepts the challenge of this arduous and skilled task he will learn an immense amount about the management of sick people It is hard to think of a more favourable situation from which to learn this than to be he through whom is mediated everything that happens to the patient in hospital

If the resident has accepted that the task is of this nature, there is some simple advice to offer him—advice which, when written down, seems so obvious that it may seem foolish to state it—but not half so foolish as to forget it

Lines of Communication

Consider personal relations as a problem in communication Almost all personal altercations, whether in hospital or elsewhere, are due to a breakdown in communication Either nothing gets through, or a distorted meaning is put on what does arrive This is called misunderstanding " Oh ! I thought you meant ", " Well, if only you'd said that in the first place ", " I *did* tell you "

So the first rule is to make quite sure that all you say is received in the spirit in which it is meant The surest way to do this is to say it yourself, in person You may then observe the effect of what you say on others, which gives you an opportunity to correct any wrong impressions immediately, to soothe if need be, and even to insist when you read in the recipient's face the quiet intent to disobey If it is possible to write down orders, always do so—an essential where drugs are concerned when this should be made an invariable personal rule Extended to other instructions the written word may save many an argument

Never underestimate the value of the personal approach The trouble taken to appear in person, especially in geographically remote departments, often has a galvanising effect The telephone is the next best Be sure to whom you are speaking and so avoid telling the ward maid to check on the patient's catheter Ask for the sister or the charge nurse, if calling a ward If you cannot speak either directly or on the telephone you are obliged to leave or send a message Defer the whole matter if possible, rather than resort to this unsatisfactory avenue of approach, the distortion a message may suffer is unbelievable If you have to do it, avoid asking a very junior person to bear a message to a senior It is not only discourteous, but the bearer may not have the poise and confidence to convey the message in its full form Do not ask a laboratory technician to ask a consultant pathologist to hurry up and report a biopsy It is always worth the extra time taken to speak directly to the right person

The Other End of the Line

With whom are you concerned to communicate? There are four main groups of people—the patient and his relations, the nursing staff, other doctors, and the ancillary staff of the hospital

The Patient and His Relations

There is no scarcity of written advice about the doctor-patient relationship Most of it applies equally to the patient in hospital as out of it, but there are a few problems peculiar to the hospital situation One is the question of identification of doctors, which scarcely arises when the family doctor's surgery is visited There it is either "the Young 'un or the Old 'un" Not so in hospital, where the only person who, on appearance alone, measures up to the patient's conception of a consultant may prove to be the hospital barber So "state your name and business" and mention your chief, whose name may well be known to the patient and will reassure him If you have to take another doctor to see the patient introduce him properly, by name and trade The same goes for relations, who have a right to know who is giving them what may be momentous news

The informing of the patient and relations about the progress of investigations and treatment is your duty and should not be left to the nurses It is a continual grumble of patients that they are told nothing in hospital The patient must only be told as much as you discern he wants to know Not everyone wants a diagram of his gastrointestinal tract with the ulcer marked in red ink, and this must be respected Those who do not are the patients who say that you are the "doc", or pilot, or captain, and that they leave everything to you This may strike you as an easy and acceptable situation, and so it is if all goes well But, if complications arise and changes in treatment become necessary, they are less likely to take it in their stride than those who have troubled to understand a little and feel they are sharing the responsibility with you for the treatment Well-informed patients are more likely to be able to cooperate in an intelligent way The relations must be told as much as you think they ought to know, and not only as much as they choose to learn or as much as you have the courage to tell We all like to announce good news, and when it is bad we often temper it because we cannot face the full truth ourselves Think imaginatively about the consequences of what you say and you will have a good guide

More will reach the ears of even the least inquisitive patient than you tell him There is the obligatory eavesdropping on student teaching which even the most considerate arrangements can seldom eliminate, the overheard conference between doctors, and even the unwittingly read form with a diagnosis writ large at the top Here it is not so much the truth that you are concerned to conceal as the misinterpretations of stray information out of context that you must correct You will do well after a ward round, whether a teaching one or not, to visit your patients and to sort out what has been said and what decisions reached about each of them Finally, cultivate the bedside manner, not the bed-end manner

Nursing Staff

The ward is the sister's, and I have heard of a hospital where the wards have doors and you ring a bell for admission If you want to go in at a time inconvenient to her, ask, and say why you want to, if you do this from the start you will soon find the ward is yours as well as hers, for as long as you like If you want to carry out any procedure state a time, say what you want, come at that time and, before you start, check that all you want is there

Get clear at the beginning what sister regards as your duty and what hers, in regard to possible areas of dispute, such as filling in forms and ringing up to book appointments in special departments Assume it is your responsibility and, if help is offered, accept it graciously rather than as though you expected it I cannot tell you how unpleasant an atmosphere can be built up in a ward where there is endless disputation about whose job it is to do what

Nurses are in hospital because they want to care for patients There is really no other inducement Remember this, and respect it, and recall from time to time how young the nurses in training are Do nothing to disillusion them about your regard for the patients, for they are remarkably alert to sense when doctors get carried away by their interest in science This may be suspected chiefly of the more senior members of the staff, and it is for you to make up, if need be, for their apparent lack of concern

There are now many investigations which demand the presence of, though often not much actual help from, the nurses Take every opportunity to instruct them, for they will be much the more efficient and cooperative allies for knowing what you are trying to achieve Get to know the seniority of nurses on your ward and their names, and so avoid expecting too much of a nurse just out of preliminary-training school Help them if you can—do not just stand by while they lift beds and patients, give a hand with making the bed you have dishevelled All obvious Yes, but these things never occur to most young doctors in hospital

Doctors as Colleagues

There are three groups of doctors those on your own firm, others in your hospital, and those outside The bigger the staff on the firm the more difficult is your task You will have to keep them informed of each other's decisions and plans from day to day Do what you are told when you are told, not when you think you will Make it a rule to see that the chiefs know all major events—some will want to know a lot, and some a little, but always err on the side of telling them too much Remember a patient's relations or his family doctor may ring your chief up for information, or he may meet them socially Imagine his consternation when asked why one of his patients has died and this is news to him

So far as other hospital doctors are concerned, try if possible to make contacts on your own level The circumnavigation of what in Army parlance are called "normal channels" is a common reason for offence being taken Most such "crimes" are quite unintentional, as when a resident rang a hospital to transfer back to it a patient who had completed surgical treatment He asked for the appropriate ward, and to his surprise the consultant answered the phone That resident's Board of Governors had a letter next day complaining of the matter and requesting that in future the house-physician and not the consultant should be rung up If unusual methods of approach are being used, and it is right and proper that they should be on occasion, show that you know that they are before you are reminded abruptly The phrase "I am taking the liberty of" pays dividends in good will

When you have dealings with a doctor outside the hospital remember that it is your chief and not you that he knows and whom he really wants to deal with Don't haggle on the telephone, just say you will have to ask your chief, if the line of action is not an obvious one Each firm has its own way of dealing with requests for urgent admissions, and you must tell the doctor about this—namely, that your instructions are, &c You must on this, as on many other occasions, gently remind your listener that you act for another, and, although you may not like too much the sound of "I am only doing what I am told", it is the soft answer which turneth away wrath Provided it is true.

If you have to write a discharge letter, think what the doctor wants to know Don't burden him with a long history which he will already know if he really cares and, if he does not, will not be interested to learn Tell him what your chief thought about the diagnosis, if need be, say that no conclusion could be reached And tell him what to do, what drugs you recommend, and say, if possible, how long off work you recommend Yet keep it all short, for the busy doctor has not time to read an essay on pernicious anæmia, when what he wants is the diagnosis and the dose of vitamin B_{12} you advise If he wants the essay, it will be elsewhere in his post, and the back of it can be used for blotting Tell him if the patient dies, because he is even more open to the hazards of being confronted by the family

Doctors as Patients

There is another doctor you may meet occasionally, and that is the doctor who is a patient or a patient's relation Do not expect him to treat you with quite the respect you will have come to regard as usual from the laity, if you are doing your job well He will be ever striving for words with your chief, and reasonably so You will do your best to see that he has reasonable access to him None the less you can, while according him some privilege in the Hippocratic tradition, see that the situation is kept under control, and that he is not allowed to badger the nurses and yourself to the detriment of good order and discipline and the welfare of other patients If he doubts the advisability of any investigation or treatment, say that it is the express wish of your chief Again you must assume your ambassadorial role, and on occasion take on the authority of him whom you represent There will be few doctors who do not realise that, having worked with your chief for some time, you are likely to know best what he would wish It should be obvious that, if a doctor's relation presents for urgent treatment—e g, through an accident—you should immediately call in someone more senior The thought of cheap glory is as nothing compared with the odium you will incur if your perfectly reasonable treatment goes astray through no fault of your own It is a responsibility with which you should not burden yourself Never forget the simple fact that, if the chief's wound breaks down, it is due to bad germs, but if yours does it is due to bad surgery You cannot build up in six months what has taken your chief twenty years, and he needs every bit of his reputation to weather the vicissitudes of treating a fellow doctor or his dependents

Ancillary Departments

Most of what has been said applies to dealing with these departments, with especial emphasis on the fact that you are carrying out your chief's wishes Residents sometimes have to take the most awful dressings-down from quite junior members of these departments as a consequence of doing exactly what they have been told It is quite wrong that these doctors should be bullied in this way, but I suspect that they may sometimes have created a difficult situation for themselves by a tactless approach Demands for urgent examinations are perhaps the commonest cause of trouble Providing there has been no delay on your part in making a request of this kind, counter any resistance you may meet by offering to ring your chief and ask him if he is prepared to forego this investigation This facilitates matters greatly, and rarely costs the hospital a telephone call If, of course, you have had a request in your pocket for a week and suddenly realise your chief will be starting his round in an hour, you will have to go cap in hand to the appropriate department. Whether you get roundly ticked off both there and later by your chief will depend on how well you have fostered relations up to date It is amazing what departments will do for those who are *persona grata*, and how obdurate they can be to those who are not

The fact that so many hospital departments close at 5 P M. is the target for much ill-earned abuse Remember that a great deal of laborious routine work goes on to provide you with results, and without the excitement and rewards of clinical medicine It is presumptuous to expect them to work regardless of time or effort in the manner commonly taken for granted in clinical doctors, however ill-deserved we may sometimes feel this assumption to be So comply with rules for sending in requests early in the day, and if you have to ask someone to stay on late or come back into hospital see that they realise just why you have called them in, and let them see how reliant you are on their services If necessary do not be afraid to dramatise the situation a little, especially if dealing with lay staff It is remarkable, for example, the effort and imagination office staff will expend in a search for notes or the like if they are allowed to see how vital it is

Conclusion

There will be some who think that I have painted, by implication, far too grim a picture of hospital life Some, perhaps, will put this paper down thanking God they are not as other men are, and that *their* hospitals are happy ships, anyway I have had the good fortune to work in several teaching hospitals in different parts of the country, and in regional and Army hospitals too I am most impressed with how similar the pattern of hospital life is under varying conditions, and that a hospital is no better than the doctors working in it However grand the names on the board in the vestibule, it is the residents who give the hospital its real reputation—its reputation in the community which it serves

A current British tome devotes space to discussing whether the family doctor or the visiting consultant should precede the other into the sick-room in the patient's home This concerns few patients and fewer doctors The number of doctors and patients who have to work out their salvation in hospital is large, and increasing I believe we must get over our shyness of talking about how we should deal with each other and with the many others whose paths cross ours in hospital

ACADEMIC REVOKE AND FAILURE AMONG OXFORD UNDERGRADUATES *

S J G SPENCER
D M Oxon , D P M
FIRST ASSISTANT, DEPARTMENT OF PSYCHOLOGICAL MEDICINE,
UNIVERSITY OF DURHAM, LATELY SENIOR REGISTRAR,
WARNEFORD AND PARK HOSPITALS, OXFORD

THE diversity of grants since the war has much increased the pressure on students to work hard at Oxford University Academic demands have therefore imposed stress from which the unstable may all too easily run away This paper deals with this running away from work or examinations it prescinds from the question of simple work panic, already fascinatingly covered by Malleson (1957)

Material

100 Oxford undergraduates were closely studied while under psychiatric care at the Warneford and Park hospitals, Oxford, between 1951–4 Their mode of selection has already been described (Davidson et al 1955, Spencer 1957, p 93)

These 100 student patients were found to divide diagnostically into 12 psychotics (P group) and 88 neurotics, the neurotics subdividing into 48 hysterics or behaviourally disturbed (H subgroup), 10 depressed schizothymes (D subgroup), and 30 simple affectives (A subgroup) these divisions are described and discussed elsewhere (Spencer 1957, pp 98–105 and 207–18)

Definition

Academic revoke can be gross or partial and can be from ordinary work or examinations, as table I shows The forms are fully defined in my thesis (Spencer 1957, p 163 and pp 165–6) In summary, gross work or examination revoke means running away from essay writing or other study, examination revision, or the examination itself the run away is usually physical but occasionally (in 2 patients of the group) is mental and entails the patient sitting over the essay or examination paper, day-dreaming The revoker, says Farnsworth (1956) " has dozens of intricate ways of postponing or avoiding work He plays solitaire, goes to the movies, sharpens pencils, puts his room in order, visits all his friends down the hall, plays some records, and still, when he starts to study, his mind won't do its bidding and focus its attention on the subject assigned " The situation evokes a parody of the saw, " I eats well, I sleeps well, but when I sees academic work, I comes over that bad "

Partial work or examination revoke, though still found largely among hysterics, corresponded more to Malleson's (1957) work panic, of poor academic concentration with a marked tendency to distraction, the condition becoming exacerbated by worry into a vicious spiral which may culminate in running away

Results

INCIDENCE

As Trigger

Among 133 *factors triggering the illnesses of these* patients (or 1 33 per patient), academic trouble appeared in 42 cases, coming second in importance only to trouble with personal and sexual relations (which triggered 44 illnesses) 22 of these 42 cases pushed over the brink by work problems were in H subgroup

As Symptom

Besides these 42 cases triggered by work problems, 4 others had academic revoke as a symptom, making 46 cases in all Table I shows the incidence of academic revoke In 14 cases, all in H subgroup, it was the major factor producing breakdown

The distribution among the subgroups of patients is displayed in table II The predominance of the hysterical subgroup is clear Indeed, it is worth regarding each case of gross academic revoke as in this subgroup unless other evidence points to psychosis (as in 1 cyclothymic case in the group), or depressed schizothymia (which in many respects is close to hysteria) (Spencer 1957, pp 210–11) Note how well the As kept at their studies and examinations

PHYSIQUE

Gross academic revoke correlated significantly with endo/mesomorphy (or ectopenia), a mixture of fat and muscle (ectopenia 3^2 or less, r=0 41*) †

Partial revoke correlated with mesomorphy or muscularity (4+, r=0 42*)

The 14 cases, whose revoke was the major factor in their breakdown, also had significantly endo/mesomorphic physiques (ectopenia 3^2—, r=0 46*)

Figs 1 and 2 display the somatotype distributions of the gross revokers and those in whom it was the main catastrophe It will be seen at a glance how work revokers congregate to the left of the somatotype chart, where the extroverted hysterics predominate (Spencer 1957, p 134)

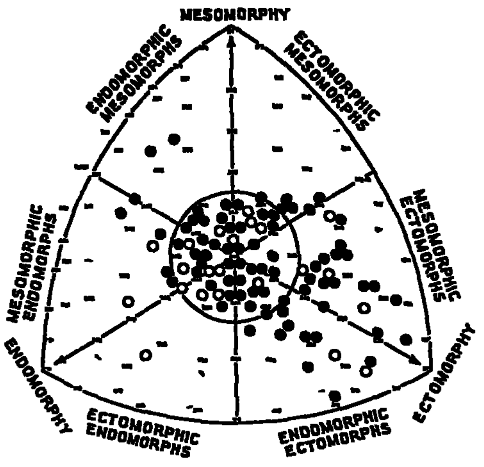

Fig 1—Somatotype distribution of 100 undergraduate psychiatric patients
○=22 cases of severe academic revoke,
●=rest of patients

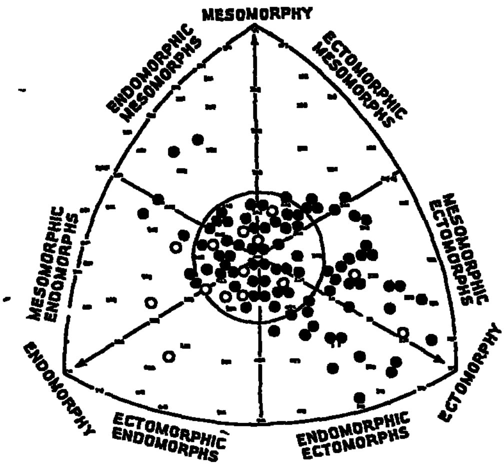

Fig 2—Somatotype distribution of 100 undergraduate psychiatric patients
○=14 cases ill mainly through academic revoke,
●=rest of patients

EXTROVERSION/INTROVERSION

Both gross and total academic revoke correlated very significantly with extroversion, with which, estimated on a 7-point scale and at the level of 3 or more, the respective rs were 0 54** and 0 60**

MINNESOTA MULTIPHASIC PERSONALITY INVENTORY

Taking 70 or more on any subcategory as criterion of instability and compared with the rest of the patients, the gross revokers had a small positive correlation (r=0 12) That of total revoke was higher (r=0 28) but not significant

INTELLIGENCE AND ACADEMIC RESULTS

On AH5‡ total scale, no significant difference among the revokers could be found either from the remaining patients or from a group of 100 controls similarly tested

Yet, as table III shows, the academic results of these revokers were far worse than for the patients at large—who, psychotics and these failures apart, were comparable academically with normal undergraduates It is interesting that the figure of 60% of gross revokers getting low or no academic degrees is identical with that for the psychotic patients

Management

Partial Revoke

The partial revokers largely responded to simple psychotherapy Our usual method was to explain to the patient that the more he fought the distraction, the worse it would become His preferable recourse was to break off work and give full play to the distraction for a period fixed by the clock, 5–10 minutes At the end of that time, unless he had by then found a solution to the distracting problem, he should say, as if to an intruding child, " Well, that's all I've time for now, I'm afraid, I'll think more about you later ", and return to his study This technique might need several repetitions

Gross Exam Revoke

The management of severe examination revoke when seen in time was forceful persuasion back to the examination However, in the case of the most severe instance of it, in which the patient had an hysterical fit while sitting in the front desk of the front room in the first minute of the first examination of Finals, he had to be transported with paper and invigilator to the Warneford Hospital, where he was eventually persuaded to sit the offending and subsequent papers he obtained first-class honours

3 of these cases revoked successfully, one before he was under care

Gross Work Revoke

This type of revoke affected 13 patients 4 made successful getaways 1 was concurrently drinking and, the alcoholism treated, the revoke ceased 2 scraped by on their own

For the remaining 6 a technique was worked out by Miss M A Davidson and myself which, although laborious, paid a dividend in reasonable degrees for all but one, who went down without The patient was brought daily to hospital, taught (by Miss Davidson) the basis of methodical study of which all were previously ignorant, and then sat over by therapist or delegate during the period of study in a room barely furnished and without distractions Prestige, enjoyment of being mothered or both kept the patients at the grindstone, and none of them walked out of this voluntary, solitary confinement before their allotted break

Discussion

General immaturity of personality is a notorious feature of the extroverted, Eysenckian hysteric running away from responsibilities is characteristic of the immature In academic revoke, then, we have a tangible, frequent, and largely objective measure of immaturity in undergraduates

The severe degree of it is markedly disabling in terms of intellectual wreckage and the inordinate time dons have to spend in salvage attempts, particularly when it is borne in mind that the intellects on the rocks of this condition are of average Oxford University potential and therefore above the 95th general population percentile

For one case deep analytical therapy was recommended by a London psychiatrist, failing to recognise that this is academically an intensely distracting undertaking even for the well poised for the academic revoker it provides a certain excuse

" Continuous pressure " therapy as here described is the only type known to achieve sporadic success As it is

---

† All correlations are tetrachoric
* = significant at 5% level } on χ^2 test using Yates' modification where necessary
** = significant at 1% level
‡ A test designed to differentiate undergraduates

time-, staff,- and morale-consuming, it can be applied only by a coherent and adequately staffed psychiatric service for students

This condition—wherever it exists—constitutes, therefore, an important argument for an adequate psychiatric unit for the treatment of undergraduates and, perhaps, for a formal university service

Summary

Academic revoke—from work or examinations—triggered or helped trigger the illnesses of 42 of 100 Oxford undergraduate patients

In 4 others, making 46 in all, it was a prominent feature of the illness In 14 it was the major feature of the breakdown Gross revoke occurred in 22 cases, partial in the remaining 24

The revokers were predominantly in the hysterical neurotic subgroup, fat and muscular in physique, extroverted in personality and more than averagely unstable, even for a patient Though normal in intelligence, their academic results were poor compared with those of psychiatric patients at Oxford in general

Special techniques had to be devised for their management, particularly " continuous pressure " therapy These techniques require large therapeutic staffs and therefore argue for an adequate university psychiatric service

The research underlying this paper was carried out on subjects under the clinical care of Dr R G McInnes and Dr J S I Skottowe Dr R W Parnell supervised the research and performed the estimations of physique Miss M A Davidson, whose therapeutic work has already been mentioned, tested psychologically all these patients

WHAT SHOULD THE STUDENT LEARN IN GENERAL PRACTICE ?

ROBERT LOGAN
M D Belf, M R C P, D I H
READER IN SOCIAL MEDICINE, UNIVERSITY OF MANCHESTER,
LIAISON OFFICER, DARBISHIRE HOUSE, MANCHESTER

MEDICINE in hospital is essentially different from medicine in general practice Not only does the hospital case-load differ in age and stage of disease but the function of the hospital is primarily curative or restorative, whereas often the main tasks of the practitioner are to keep watch or help the patient to delay his handicaps and adjust himself to them

Recognising such differences, most medical schools are now concerned to teach general practice, or at least to show the final-year student what morbidity outside the hospital looks like But to farm students out to general practitioners for short periods is hardly enough What has to be taught is the application of the principles of medicine in the setting of general practice

The special characteristic of the general practitioner is that his interest in medicine is limited neither by site nor age His role, properly played, gives him a unique relationship with his patients, and he is " liar, physician, hypocrite, and friend " He is also, potentially at least, much more He is, or should be, the integrator of the Health Service To the patient, through most of life, the hospital, consultant, and local-authority services are largely peripheral they exist to support the general practitioner to provide comprehensive medical care The practitioners should be able not only to draw on these and many other services, as he interprets his patients' needs, but also to practise prevention—not *primary* prevention (such as is associated with sanitary engineering or immunisation) but *secondary* prevention by anticipating and trying to delay the degenerative diseases With improving techniques for the control of disease, early diagnosis has become of more than academic interest, and the general practitioner has more chance than anyone else to discover and bring forward cases at a stage when specialised knowledge can be applied effectively To do this he needs clinical skills much the same as those of the specialist, but he will apply them in a different way, seeking a presumptive rather than a definitive diagnosis

Because it involves seeing so many people with varying needs, general practice involves another technique—the organisation of resources and particularly of time The practitioner should regard his surgery sessions as essentially a filter, allowing him to separate off those cases he wishes to investigate or treat more thoroughly At crucial stages of both physical and emotional illness, it is very often worth investing 30 minutes—if only because this will reduce the number of attendances

If this is general practice at its best, how can it be taught? Even for students with prior indoctrination (which few curricula provide), observation *is* not enough, for there are few practices where the new possibilities of general practice have been realised to the full To break the new ground experimental models are needed Just as the teaching hospitals finance research and set the standard for conventional specialties, so the medical school must conduct research into, and set standards for, general practice

Faced with this problem, Manchester University made a contribution by setting up Darbishire House as an experimental health centre This brought under one roof four local general practitioners whose combined National Health Service list amounted to 11,000 The physical amenities essential to good general practice were provided, together with X rays and facilities for pathology District nurses, a social worker and health visitors, and clerical help have also been enlisted Rooms were provided for maternity, child-welfare, and school clinics, all run by the practitioners and the health visitors, thus integrating the local-authority services and general practice

Although observation in itself is not enough, it is none the less important in showing students what general practice means They come to the centre in groups of four for two weeks and are attached individually to the doctors Each morning is spent in the surgery, where some 300 patients will be seen in the fortnight, and visits made to 100 homes This allows intimate observation of the patients and their families, and in turn each practitioner selects a sick family for the student to study and present to the group Even in this short time a close relationship may develop between the student and his tutor " truly ", as one of the doctors has put it, " more than the calf yearns to suck, the cow loves to suckle " (Davie 1956) Indeed, one of the risks of apprenticeship, in general practice as elsewhere, is that the apprentice's respect and affection will weaken his critical faculties and cause him to absorb bad habits and ideas as readily as good ones

The afternoons are given to group discussion In our experience, the student has little grasp of the philosophy of comprehensive medical care or of the relation of medicine to the State On the first day, therefore, there is full review of the historical and cultural evolution of the N H S and its economics This helps to orient the student and to foster an awareness of the potentialities of the present structure, and of the resistances to further progress

Thrust from the hospital, with its goal of definitive diagnosis, into general practice, where diagnosis is usually at most presumptive, the student is frankly lost He has to recognise that the goals are different and that the general practitioner applies the principles of medicine in a particular way Because the investigation in general practice is usually made at an early stage (largely unknown to the hospital), the doctor is concerned with possible developments or regression rather than specific pathology

It is in this light that the student should consider the use of some clinical skills which have too often lapsed, or never fully developed, in British general practice—e g, hæmoglobin estimation, erythrocyte-sedimentation rate, test for occult blood, and the use of the microscope He should also consider the use of old tools not for individual diagnosis but for screening, in attempts at presymptomatic detection of common and chronic diseases of middle and later life—e g, weighing, blood-pressure, enzyme tests of urine for albumin or sugar Then there are tools which the practitioner could use not so much to define abnormality precisely as to satisfy himself either that the situation is under control or that specialist consultation is required—the ophthalmoscope, swabs for culture, wet X-ray film, cervical smears (Papanicolaou), respiratory flow-meter, simple electrocardiography He will not seek to diagnose sarcoidosis or localise the infarct, rather will he use these tools to prompt earlier specialist help

Much ambulant or housebound morbidity arises from the common chronic degenerative diseases affecting lung, joint, heart or mind Unlike the kinds of disease treated in hospital, these require long-term care by the practitioner, and adjustment to lifelong handicap Here the doctor has to cooperate with other agencies in aftercare—the health visitor or the disablement resettlement officer for the sick worker before he becomes too old or chronic to retrain or rehabilitate These social skills are used in the same way in delaying incapacity among the elderly in the home To complete the picture, students visit an industrial rehabilitation unit and a geriatric unit Since a third of general practice has predominantly emotional aspects, new ways are tried, such as first-aid by counsel to the family In such cases the student can be shown how much more benefit people may get from half an hour's simple psychotherapy—at some critical time such as childbirth or retirement, perhaps—than from repeated short, and unsatisfying encounters

To absorb such a programme in a fortnight is too much for many students, and the time could with advantage be doubled The real need is for the student, during his hospital years, to bear in mind that throughout his life the patient has medical, social, and emotional needs beyond those calling for episodic concern from the hospital

The Darbishire House programme is only a beginning Perhaps the most important lesson from it so far is the realisation of how far we have still to go

MEDICAL STUDENTS AND GENERAL PRACTICE *

DEREK BERZON

FINAL-YEAR MEDICAL STUDENT,
ROYAL FREE HOSPITAL, LONDON, W C 1

DURING three years' clinical work as medical students at the Royal Free Hospital we become acquainted with many specialties, but of one branch of medicine we catch only a glimpse, and that is general practice The system of "sitting in" with a general practitioner helps to give a better view and to clarify and readjust our ideas about general practice

As a final-year student I attended, once a week for three months, the evening surgery of a general practitioner in Hampstead in N W London This was a worthwhile and enjoyable experience, and I am going to comment on the ways in which these visits helped me

A continuous fortnight in general practice, attending all surgeries and domiciliary visits, might give a better overall picture of a practitioner's life, but attendance once a week for three months has the advantage that patients' progress can be followed over a longer period of time

The Benefits

There were four main benefits I gained from these visits

Firstly, I saw the actual running of a general practice and how conditions differed from those in hospital I could examine the system of keeping patients' case-records and the things the doctor had in the surgery to aid clinical examination. I also saw to what extent he could command laboratory and radiological investigations I could discuss with the doctor the effect of the National Health Service on his practice and see the clerical aspects (registering patients, certification, and so on) as they arose I saw how much time could be devoted to patients with illnesses of varying severity in a crowded and ever-enlarging surgery

Secondly, it was interesting to see patients in their own environment on domiciliary visits In hospital a patient seems detached from his own environment, and it is hard to picture the repercussions of his illness on his own and his family's life

The environment often influenced the patient's treatment for example, could this old lady living alone walk down two flights of stairs to get to the chemist's shop for a prescription? Small practical points played a very large part in deciding treatment Could a patient stay in bed for any length of time when he could not afford to stay away from work? Who will look after the patient confined to bed? Can relatives or a nurse be found to care for the children or clean the house of the sick mother? These problems are not always obvious to the student in hospital

Thirdly, I was able to see the general practitioner's difficulty in assessing the significance of mild and early symptoms in a patient seen for the first time There followed the problem of whether these symptoms merited a specialist's treatment, home treatment, or any active treatment at all I was often humbled to discover that what seemed to me to be a complicated and serious diagnosis was considered by the practitioner to be a more common and straightforward condition, requiring only simple but practical treatment It became clear that common complaints do commonly occur

Lastly, it was obvious how many patients at any one surgery have symptoms partially or wholly due to anxiety states I was fortunate in "sitting in" with a doctor particularly interested in psychological medicine I was able to see how his questioning revealed the psychological nature of the patients' complaints and how much they benefited from sympathetic listening, understanding and discussion of their problems

---

* Based on a paper read at a meeting of the North London Faculty of the College of General Practitioners on April 29, 1958

A Popular System

This method of taking a look at general practice has gained in popularity among the students at the Royal Free, so that 40 out of approximately 60 eligible students sat in with a general practitioner during 1957–58, and 33 have already applied during the first six months of 1958–59 This system began in 1953, when students in the last eighteen months of their clinical work could sit in with a general practitioner for two weeks if they wished Later, in 1957, the system of attending once a week for three months was introduced and proved to be more convenient for many of the doctors and students

During 1957–58 two students lived in for one week with a general practitioner in a Derbyshire mining community, and they were able to see all the difficulties in this particular type of practice

The total of 40 out of 60 students in 1957–58 shows the growing interest of students in general practice 10 students who had lately visited practitioners were asked for their views They were unanimous that their sitting-in had filled a gap in their knowledge and had clarified their ideas about the practice of medicine outside hospital 6 of the 10 felt more attracted to general practice and 3 of the 6 felt fairly convinced about entering general practice 4 of the 10 thought that psychosomatic medicine played a significant part in general practice 4 more agreed with this viewpoint on direct questioning All agreed that this scheme is worthwhile and useful, and we are all very grateful for the help we have received from all concerned

I should like to thank Dr Philip Hopkins for his help and interest, which have enabled this article to be written

LEARNING MEDICINE BY CLINICAL PRACTICE

HOME-CARE PROGRAMME OF BOSTON UNIVERSITY

Gerald Hass

Clinical Student

THE LONDON HOSPITAL MEDICAL COLLEGE, LONDON, E 1

Since 1875 final-year students of Boston University Medical School, attending the Boston City and Massachusetts Memorial Hospitals, have taken part in a Home Medical Service For one month, a small group of students act as general practitioners providing domiciliary medical care for the indigent and otherwise doctorless population near these hospitals

The aims are not only to ensure that the patients receive adequate medical care, but also to introduce students to the practice of medicine in the home, to make them aware of the problems of public health, to give them an appreciation of the patient in his environment, and to relate this to the principles and practice of preventive medicine

I here describe the scheme as seen through the eyes of a fourth-year English medical student who spent a month last summer working with, and under the same conditions as, a group of four American students

The Scheme

The headquarters in the outpatient department of Massachusetts Memorial Hospital consists of a large conference room, equipped as a laboratory for simple investigations in hæmatology and bacteriology A refrigerator contains stocks of penicillin and blood-agar plates, and round the walls are cupboards filled with many free samples of pharmaceutical products

Each student is assigned an area near the hospital, which represents his practice Some areas are large, and all contain between 1000 and 2000 prospective patients Often a car is necessary, since visits may involve much travelling

The student's equipment consists of diagnostic instruments, thermometers, throat-swabs, and a few drugs (aspirin, phenobarbitone, ephedrine, adrenaline, and penicillin) He also carries 'Clinitest' tablets for urine analysis, the equipment necessary for Mantoux tests, and a supply of prescription forms countersigned by a member of the medical staff All this is in the traditional black bag which serves as a badge of office and ensures a safe journey in the less savoury parts of town Lollipops are useful bribes for young patients and are kept in the conference room's store of drugs The student may prescribe any drug he thinks fit—except narcotics Prescriptions are dispensed at local drug stores or at the hospital pharmacy

Students work six days a week, beginning at 8 A M and usually finishing by mid-afternoon A supervisor, who is a full-time member of the department of preventive medicine, is available for consultation at all times and will advise students by telephone

At 8 A M a conference is held and the previous day's cases are discussed Patients' telephone calls are received by a nurse who notes the complaint and allocates the case to a student. No cases except emergencies are accepted after 10 A M , and after the conference the student sees his new cases and revisits old ones It is rare for one student to make more than a dozen visits in one day

Each student also has a list of about 6 chronic patients, usually old people, to be visited once or twice a week District nurses provide bedside care for these patients, and the student is expected to supervise management, prescribe drugs, and (most important) to maintain the patients' morale

If the student thinks fit he may refer patients to outpatient departments or arrange their admission He is expected to follow up his cases and accompany them to their specialist consultations

The full notes kept by the student record the history, examination, diagnosis, treatment, and course of each case These can be referred to in future illness and are valuable for statistical analysis

The Patients

Those who earn less than $40 monthly (for a single person) are eligible All those receiving relief or other financial aid from Federal and Civic resources are automatically eligible For each medical visit $2 20 is paid to the home medical service by the relief oraganisations Every year domiciliary medical care is provided for approximately 5000 patients

I made 130 visits to 40 patients, half were children under ten years, and most of the others were over sixty These figures tally with the averages obtained by the department over the course of one year It is interesting that of all the patients treated in hospital for that year only 20% were children under ten and 10% were over sixty The reason for this disparity may be that many children and elderly patients are not ill enough to need admission or that the home-care scheme encourages them to seek advice more often and for less reason

By far the largest group of patients I saw were children with upper respiratory infections, tonsillitis, and otitis media Other conditions included measles, mild gastroenteritis, and a congenital heart defect Older patients were mainly chronic invalids needing supervision and management (heart-failure, rheumatoid arthritis, and the multiple complaints of old age not bad enough to need admission) Among the adults I saw seborrhœic dermatitis, angioneurotic œdema, a family with suspected pulmonary tuberculosis, a patient in a severe agitated depression, and a sprinkling of functional disorders of no known cause

I used a portable hæmoglobinometer, made blood slides, and did differential white counts I cultured throat swabs on blood-agar plates and became fairly proficient in these minor investigations after a short while

In all, about a quarter of the cases I saw were referred to hospital outpatient departments by my letters. These included requests to skin, E.N.T., and X-ray departments. Most of my patients had upper respiratory infections, so prescribing was straightforward. All treatments were discussed with the supervisor, and, in difficulty, helpful advice was always forthcoming.

Many patients had social problems which were beyond my scope, and the social worker attached to the scheme was a great help in investigating conditions in the home and providing financial and other aid, which was particularly needed for old-age pensioners.

The Benefits

The attitude of American students to this month's work is one of keen interest, coloured by a certain amount of trepidation. Here at last is an opportunity to put into practice part of the theoretical knowledge acquired in medical school. They regard the month as an easy one in terms of man-hours, since there are no formal lectures and tuition. Instead, conferences and discussion make them feel that they are responsible doctors interested in the welfare of their patients. They learn the importance of conscientious clinical work and integrity in social dealings with their patients and as a part of this gain insight into the living conditions of patients.

The medical staff feel that the scheme does much to mature the student's approach to his profession. The lack of confidence he feels in his own ability is soon dispelled when he realises that advice and help are always available. The important thing is that *the student* stands on his own feet, is the first person to see the patient, and it is on him initially that the onus of diagnosis and treatment rests. It is he who brings into action the various social services. This is very different from the Edinburgh scheme (Scott 1950) where students are introduced to patients by a general practitioner. Only after a few visits with the practitioner is the student allowed to follow up a case—which has already been assessed, diagnosed, and treated for him.

My own opinions of the scheme are very similar to those of the American students. They may have been affected by the fact that I had only a short while to adapt myself to a new environment and different ways of working, and I was an object of friendly curiosity to my colleagues and patients. The scheme was a particularly stimulating experience because I was able to see, in detail, a side of life in Boston seldom seen by tourists. I felt, as did my colleagues, that I was doing something worth while, though just how much I gained is hard to assess at present.

Among various criticisms, the most obvious is that students are not yet fitted for the responsibility of treating patients in their homes. The scheme is said, therefore, to be detrimental to the interests of patient and student. It is my impression, however, that the advantages outweigh the theoretical possibilities of the student failing to cope successfully. Perhaps the best indication of this is the fact that for over eight years medical students in Boston have been doing valuable and conscientious work in caring for their patients.

A project like this might be an advantageous part of medical education in this country, even though the National Health Service provides adequately for the indigent.

I am very grateful for the help received from the governors of The London Hospital Medical College. I am also grateful to Prof. H. Bakst, of Boston, for his hospitality and to Dr. J. R. Ellis for having made this visit possible.

DISCUSSION GROUPS FOR PÆDIATRIC STUDENTS

VICTORIA SMALLPEICE
M.A. Oxon., M.D. Lond., F.R.C.P., D.C.H.
CLINICAL DIRECTOR, CHILDREN'S DEPARTMENT, UNITED OXFORD HOSPITALS, AND UNIVERSITY LECTURER IN DISEASES OF CHILDREN, UNIVERSITY OF OXFORD

FOR the past ten years medical students on the pædiatric firm at Oxford have been asked to read papers on some specially selected subject. The general plan has been modified from time to time and it is useful at this stage to look back and try to judge what type of question has interested them and produced the best work.

Students on each obstetric firm are attached to the pædiatricians for three months and during this time they learn something of the care of the normal and sick neonate and the premature baby. Shortly afterwards they spend three months in the general pædiatric department, the firm usually consisting of five to eight students with a maximum of ten.

Object of Papers and Discussions

The object is to give every student an opportunity to investigate some problem during the last month of his pædiatric course. A subject is chosen which is suitable for presentation by the group. Each student is limited to twenty minutes for his paper and members are asked to study the historical background and literature and, when appropriate, to illustrate their work by graphs, X-rays, and photographs; case-histories and data are taken from the Children's Department. Where the choice is a happy one, it gives scope for the very different interests and approach of the individual students and they are left to divide the work to suit themselves.

In preparing their papers they learn where to find the information they need, how to get help from all those interested in the child, and the ways in which we attempt to coordinate the various services. They get experience in setting out their work, keeping to a time limit, and arranging the papers among themselves so that these are complementary rather than redundant. A number of sessions have been of real value to me personally in throwing a new and critical light on our problems, and it has been particularly interesting to compare surveys made at intervals of some years on a similar subject.

General Plan

Two sessions are now usually held for each firm. One of these takes the form of a supper at my house followed by papers and a general discussion; a guest may join us for the evening and pathologists, registrars, or housemen may come in time for the papers, but the party remains a small one. The second session usually replaces an afternoon ward round and is used for a more general discussion with perhaps a general practitioner, medical officer of health, and social worker as guests. At these, too, the numbers are limited and less than twenty people take part. All the students come to both sessions although they read papers at only one.

Some Subjects Chosen

Afternoon Sessions

(i) Study of a Hutted Camp. An abnormally high proportion of children admitted to the wards came from a hutted camp some miles from Oxford and one firm was asked to consider this. One student opened the discussion with a general review of the literature on child health and environment. Another had visited the site and taken excellent photographs to illustrate his paper, the general practitioner had helped him in his investigation and joined us in the discussion, bringing his social worker with him Two students had studied the case-histories of children admitted from the camp, particularly with reference to any possible influence of their environment on their illness, their need for admission and their subsequent progress The medical officer of health helped the students to collect their data and joined us at the session

(ii) Discussion on the problem of Repeated Respiratory Tract Infections Acquired during the First Two Years at School The students were asked to consider why, if all children are to a greater or lesser extent exposed, some are much more seriously affected than others The students studied local school-attendance figures, school buildings, physical constitution, and other facets of the problem A member of the staff of the City Health Department, an otolaryngologist, and a specialist in social medicine came to the session and joined in the discussion

(iii) Family Problems and The Family Background in Pædiatrics are titles that have been chosen They provided an opportunity to study individual children against a difficult background and to allow us to introduce the students to the children's officer, almoners from other departments and members of the school medical and child-welfare services

Evening Sessions

Many of these sessions have now been held and I have found that it is particularly important when dealing with small groups of students to choose a subject that will interest all those who are on the firm at the time

(i) Neonatal and Infant Deaths have been studied, sometimes against an historical and geographical background and on other occasions dealing with local figures over a twelve-month period In the second case, deaths in the two maternity departments, in the wards, and those occurring in the city were investigated together with a special study (made with the help of the police surgeon) of sudden deaths in infancy It has been interesting to see how the different groups have tackled these problems and the ingenuity shown in collecting their data and arranging their work, one paper opened with the views of Tristram Shandy's father on the dangers of vertex delivery and another was purely factual and well illustrated by graphs

(ii) The Cerebrospinal Fluid gave the students an opportunity to study anatomy and physiology, the blood-brain barrier, and congenital abnormalities as well as the changes produced by infection, neoplasm, &c Cases from the wards were used in illustration

(iii) Infants admitted with acute respiratory disease were closely studied A detailed investigation was made of those who died, with a view to learning whether anything further could have been done, from the first sign of illness at home, to save these children's lives Incidence was plotted against temperature and humidity at the relevant time, the data having been obtained by one of the students from the School of Geography

(iv) Readmissions The students tried to discover why certain children came into hospital more than once They were asked to suggest what special steps could have been taken to help this particular group In the nicest possible way the omissions of the pædiatrician were brought home!

Other subjects have included The Forms of Mental Defect which may be Preventable or Treatable, The Purpuras, Some Preventable Conditions, and Ward Infections

Conclusions

I believe these sessions have been valuable in many ways On occasions they have not taken place because the students have been over-occupied by a special pathology examination or there have been absences due to illness Even more rarely, the group has appeared uninterested in pædiatrics and the teacher has, very temporarily, become discouraged and felt no inclination to put in the time and trouble necessary for a good meeting Perhaps not least of the advantages of an evening session is the contact between staff and students outside hospital These somewhat exhausting parties usually finish around midnight, washing beer glasses at the kitchen sink

My thanks are due to all those who have helped me and particularly to the students

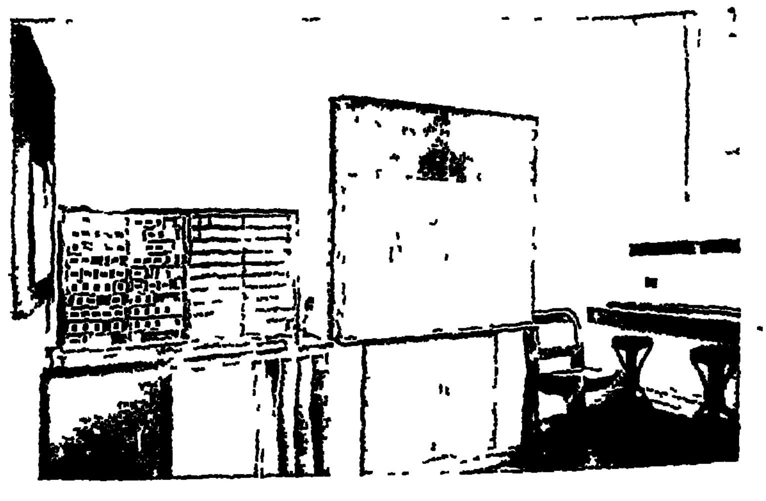
---

A TEACHING-ROOM ON THE WARD

J K Russell
M D Aberd, F R C O G
SENIOR LECTURER IN OBSTETRICS AND GYNÆCOLOGY, UNIVERSITY OF DURHAM

During the clinical years medical students spend much of their time in the hospital, and great stress is laid on teaching by the bedside For the most part there is no special provision for teaching in the wards, and teacher and students must fit in as best they can It is undesirable for a teaching session to be completed at the bedside, for the patient may be much alarmed by what is said or implied In practice it is customary for the clinic to move to the centre of the ward, to a corridor, or to an empty side-room before diagnosis, treatment, and prognosis are discussed

The gynæcological staff in the Royal Victoria Infirmary, Newcastle upon Tyne, have long felt the need for a permanent teaching-room on the ward In 1955, with the support of the teaching-hospital group and the University of Durham, it became possible to plan and equip a special room for this purpose The unit at that time was enlarged to 44 beds arranged in single and double rooms and small wards The teaching-room is situated centrally and is easily accessible from any part of the ward On the centre of the left-hand wall (see figure) is a large blackboard, which opens up to reveal a projection screen To one side of this blackboard is a cabinet with sliding frames and backlighting, used for storage of 450 colour transparencies, 2 in × 2 in Below the cabinet is a specially designed cupboard in which panel demonstrations are stored A bench runs round two of the other walls A sliding shelf extends 2 feet from the centre of the bench facing the



screen When needed, the projector sits on the shelf A table viewer is available, when in use it is placed on the bench, and six or eight students can look at the enlarged image

Discussion

University and hospital have combined to produce this teaching-room on the ward, and its many uses have justified the modest expenditure

Once the patient's history has been taken and any physical signs demonstrated, it is to everyone's advantage that discussion should take place elsewhere than at the bedside The patient is spared anxiety, teacher and students can speak freely There can be no privacy in the centre of the ward or in a corridor, in either situation interruption and disturbance are likely The teaching-room offers complete seclusion There are also advantages in having a selection of visual aids available on the ward

For example, one case of cervical erosion may be demonstrated to students in the ward, and then, from the collection of colour transparencies in the teaching room, they may be shown several other cases These benign cervical lesions can then be compared with malignant lesions of the cervix The transparencies can be viewed carefully and repeatedly, and in this way the student is likely to appreciate more clearly the differences between benign cervical erosion and early cancer of the cervix This use of the teaching-room gives added point to clinical teaching on the ward

At intervals, panel demonstrations are set up in the room and left for several days, so that students attached to the department can study them at leisure This form of teaching aid has already been described (Russell et al 1956)

Instruction in gynæcological histology is given once a week in the teaching-room, microscopes are set out on the benches for this class

It is not unusual to find rooms of this type in medical schools or in departmental headquarters, but much is lost by their distance from the ward When situated on the ward, a teaching-room such as I have described can make a significant contribution to the clinical teaching programme

I am indebted to Mr C J Duncan and Miss D Mustart for their help in designing and producing visual aids for use in the room

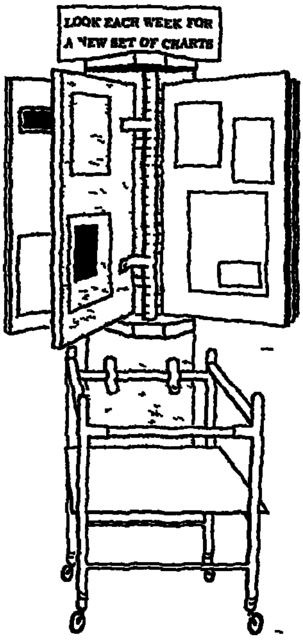
PÆDIATRICIAN

DEPARTMENT OF CHILD HEALTH, GUY'S HOSPITAL, LONDON, S E 1

A stand for displaying pictures and charts has been in use as a teaching aid in the children's department at Guy's Hospital for the past two years

In basic design it resembles the leaved stands on which picture-postcards are displayed (see accompanying figure) It consists of eight square leaves of 'Essex' board type (58 cm × 58 cm × 0 7 cm) framed in wood. Each leaf is hinged on a central pillar mounted on a ward trolley 42 cm × 42 cm Each leaf is painted a different colour The upper glass shelf of the trolley has been removed, and the lower replaced by a sheet of 'Formica' as being more robust



The illustrations, mounted on light card, are secured by pins to both sides of the leaves Cards of any size up to the dimensions of the leaves can be used, and several pictures of different sizes can be put on the same leaf

A valuable feature of the stand is the ease with which several students or nurses can view the illustrations simultaneously Being mounted on a wheeled trolley, the whole stand can be easily moved to display the same or different sets of pictures elsewhere

A new set of pictures is put up each week, six sets being kept in the department in separate envelopes Each set includes pictures dealing with development, infant feeding, diseases, treatments, prophylaxis, and health education

The stand is usually kept in a large anteroom from which open the children's wards and operating-theatre, it is therefore seen by nurses, anæsthetists, and surgeons as well as by the medical students

The stand is easy and cheap to make, ours cost about £5

Our thanks are due to Mr E Smith and Mr F West, of the Medical School workshop, to Mr W P Bentley, of the works department, and to Miss P Carter, of the illustration department, Guy's Hospital Medical School

Reviews of Books

For Future Doctors

Alan Gregg, M D Chicago University of Chicago Press London Cambridge University Press 1958 Pp 165 26s

In many countries medical education and research are becoming increasingly dependent on financial grants from various bodies and individuals From this situation has emerged a new figure in medical circles, the "professional philanthropic investigator". The late Dr Alan Gregg was such an investigator, and for thirty-seven years advised the medical-sciences division of the Rockefeller Foundation how its immense funds might best be dispensed This book contains the text of eleven addresses he delivered to medical schools or student bodies during that time One might be excused for surmising that, in his official capacity, he would have been sure of a hearty reception wherever he went But it is apparent from his lectures that, Foundation or no Foundation, his views merited very careful attention

He has devoted his chapter On Reading, not so much to advice on what to read, as on what to reject Dr Gregg felt that the medical student is at a disadvantage, compared with members of other faculties, when he is required to distinguish between a logical argument and an illogical one His course entails mastering so much factual information that his teachers spend all their time teaching him what to think, rather than how to think In consequence, many a student never learns to discriminate between praiseworthy books and articles, which advance his knowledge, and those which are badly written and confuse him (The sort that Lord Balfour, no doubt, had in mind when he spoke of "things that would have been clearer if they had not been explained") Dr Gregg lays down some criteria for recognising true worth and validity in medical argument, and he points out that many doctors, young and old, are sadly misled, in their reading and writing, through an ignorance of the laws of probability "One of the great needs of medicine, particularly for men in research work, is a course in evidence"

Dr Gregg's remarks have an international flavour and we hope they will continue to be widely studied on both sides of the Atlantic

Surgery in Infancy and Childhood

A Handbook for Medical Students and General Practitioners MATTHEW WHITE, M B, F R F P S, F R C S E, consultant surgeon, Royal Hospital for Sick Children, Glasgow, WALLACE M DENNISON, M D, F R F P S, F R C S E, Barclay lecturer in *surgery in relation to infancy and childhood*, University of Glasgow, and surgeon, Royal Hospital for Sick Children, Glasgow Edinburgh E & S Livingstone 1958 Pp 444 45*s*

THIS welcome book is a pioneer Its first intention is to introduce the senior student to the problems of surgery in infancy and childhood That it should come from Glasgow is indeed fitting, for the final-year student of that university has taken a ten-week course in the subject over the past quarter-century The authors are thus singularly fitted to judge the needs of these men

The book is easy reading and yet contains all the necessary detail Indeed, some may think it contains too much for the student The embryological diagrams and digressions are valuable because they illustrate the need for the children's surgeon to think as an applied embryologist—for example, in elucidating the malrotations But, for instance, a series of diagrams of the operative technique for the repair of a large omphalocele seems unnecessary, and the photograph of the sequelæ of a leopard's mauling contributes little The space devoted to cardiospasm seems excessive for a childhood rarity For rectal prolapse the usual advice to strap the buttocks together and "teach" defæcation lying on the side is given Surely this unpractical suggestion should disappear from future editions? But these are small matters in an unusually consistent book

The opening chapter recounts the special problems of surgery during the period of growth and development, and the physical and psychological importance of the timing of the procedures It is pleasing to see such subjects as the malar hæmatoma and adherent labia described and pictured These are the kind of minor conditions which can occasion great parental anxiety and which are passed over in most surgical texts

From this book the student will get a clear picture of the scope of pædiatric surgery General practitioners—and indeed surgeons and pædiatricians—will also find it a convenient resume of the subject

Bibliography of International Congresses on Medical Sciences

Editor W J BISHOP Council for International Organisation of Medical Sciences Oxford Blackwell 1958 Pp 238 25*s*

"THE purpose of the present list is to provide a guide to congress organisers, librarians, editors and others who wish to trace the published proceedings of medical congresses" it is not a complete record of international medical congresses but covers only those whose proceedings have been published The details of each are limited to subject, site, date, "bibliographical description", and languages Their alphabetical arrangement, though it has its convenience, presents certain difficulties, and even with the help of the index it may not always be easy to find what is sought But the book contains information which, when one needs it, may be hard to get from other sources

John Wesley among the Physicians

A WESLEY HILL, B A, M B London Epworth Press 1958 Pp 135 10*s* *6d*

THIS interesting and well-written book is concerned to bring to the notice of a wider public the activities of John Wesley, physician Dr Hill gives extensive excerpts from Wesley's three medical works, *Primitive physick*, *The family physician extracted from Dr Tissot*, and *The desideratum, or electricity made plain and useful* The practice of other physicians is mentioned to bring into relief Wesley's simpler and often less harmful approach to human suffering Dr Hill's criticism that "Wesley in his enthusiasm may have optimistically over-rated many of his results" applies also in some measure to his own evaluation of his fascinating subject For instance, it is doubtful whether his thesis that Wesley made "some attempt at liberating medicine from these [medieval] theoretical coils and at setting it upon an experimental basis" can be maintained The more correct interpretation seems to be that he was concerned to better the physical health of the masses by providing rules of hygiene and simple and cheap remedies within the reach of all—hence his enthusiasm for the new electrical treatment These were important contributions to 18th-century medicine Most striking, in retrospect, is the extent to which Wesley realised the importance in disease of psychological factors which orthodox physicians tended to overlook in practice if not in theory

The Human Hand

GEZA REVESZ Translated by JOHN COHEN London Routledge & Kegan Paul 1958 Pp 138 31*s*

THE late Professor Revesz, of Amsterdam, devoted much study to language, tactile perception, and the psychology of the blind and the deaf It was therefore easy for him to write a book on the hand as the organ of haptic sensation and the agent of much non-oral communication The result is a discursive essay, it is reinforced by footnotes referring to technical articles, but in the main it avoids detail and aims at reminding the reader rather than instructing him It can be regarded as a sister-piece to Wood Jones' anatomical study of the human hand and, though less original than that work, resembles it in its emphasis on the importance of the hand in man's development and achievements

---

Modern Trends in Anæsthesia (London Butterworth 1958 Pp 331 67*s* *6d*)—This volume, edited by Dr Frankis Evans and Dr Cecil Gray, marks a period of consolidation in anæsthesia, which its inquiring and scientific approach well illustrates By careful presentation of established physiological and pharmacological facts, the contributors contrive an excellent picture of the implications of anæsthesia rather than of its practical application The new knowledge of recent years is well reviewed, the direction in which the specialty is moving is ably illustrated, and those aspects are indicated where further research and study are needed A large part of the book deals with the chemistry and mode of action of drugs, but their place in clinical practice is not forgotten, and there are chapters on hypothermia, cardiorespiratory pumps, pulmonary ventilation, hypnosis, and disorders of the respiratory system This is a most useful addition to the library of anæsthesia, which is enhanced by the authors' liberal choice of contributors The mutual interests of anæsthesia and other branches of medicine are well represented by authorities both within and without the specialty, and recent developments in Scandinavia and America are ably described by experts from those countries

Infant Feeding and Feeding Difficulties (3rd ed London J & A Churchill 1958 Pp 293 16*s*)—For this edition the book by Dr Philip Evans and Dr Ronald Mac Keith has been carefully brought up to date It is very comprehensive and includes procedures likely to be used only by resident staff The bias in favour of breast-feeding is reflected in the fact that over half the pages are devoted to its problems

THE LANCET

LONDON 30 AUGUST 1958

Education *v.* The Curriculum

EARLIER this year TANNER[1] outlined a reorientation of preclinical studies which would, in his view, make them more appropriate than they now are to the practice of medicine, at present largely concerned with applied human biology. At that time we forecast[2] small likelihood of such ideas being translated into action in British schools. The powers of resistance to change include the fear of giving up what was once good, in favour of the new and unproven, and in the federation of departments which makes a medical school, that fear can easily be exploited by any unit which suspects that its own interests can best be served by adherence to the status quo. But we added, " if all the older schools are tied to their dead past the same cannot be said of new schools, such as that of Western Australia ", and we are very glad, therefore, that Prof DAVID SINCLAIR has written the article on p 430 describing the curriculum which, it has been agreed, shall at the moment be used in Perth. The planning of the early years suggests that the aim accords to some extent with that of TANNER. The actual programme, however, also reflects many local and, it is to be hoped, temporary obstacles. One of these at present means that the first year is spent in isolated study of " premedical " subjects. The second year, on the other hand, will consist of a coordinated course in human biology, with at its end a single examination which should act as a stimulus to the student to integrate his studies of anatomy and physiology. Dissection of the whole body will be required and will be carried out under the pressure of the traditional viva system until the professional examination in topographical anatomy at the end of the second term of the third year. A term later the student will take one examination in biochemistry and another in " physiology and the general principles of pathology (with one question on psychology) " We hope that before long circumstances will allow these two examinations to be fused, so that the student may be encouraged to link the general principles of pathology with physiology, psychology, and biochemistry (and even anatomy)—as obviously he must.

SINCLAIR points out that although the plan he describes has been agreed to by all his colleagues some of them would place a different emphasis on the description. This no doubt would apply to the clinical part of the curriculum, in which no mention is made of that exceptionally important though technical part of medical education—the introduction to clinical method. The arrangement of the clinical years is, however, of such simplicity that at least it cannot be criticised for being diffuse. A first year in the wards (during the first half of which the course and examinations in pathology will be completed) should give the student that advantage of long-continued practice in clinical method which has been such a good feature of the traditional British training. A second year consisting of four months' obstetrics and gynæcology, four months' pædiatrics, and four months' experience of specialties (with a carefully coordinated course in preventive medicine) indicates that the University of Western Australia is at the outset keen to achieve that sense of proportion, in regard to specialisation in undergraduate education, which characterises the best American schools. A final year " relatively free from formal classes " in which the student may gain experience and integrate his knowledge is, of course, something to which almost every British school is vainly trying to return.

As HALE HAM[3] has said, " The curriculum is the course through which the student travels, it is a definition of limitations as well as opportunity " It closely resembles a railway guide which shows the expected times of arrival and departure, occasionally explains the local reasons for the route taken, and briefly indicates the main features of interest in each stopping-place. It does not state the degree of efficiency of the organisation, nor reveal its standards or those of its employees. Sometimes its avowal of close concern with the problems of the individual should not be taken too literally. Unfortunately in many medical schools in this country there are railway-guide teachers who still think of medical education primarily in terms of the curriculum. Unless a suggested improvement or reorientation is expressed in time-table form it seems to them to be hopelessly vague and diffuse—yet it cannot be translated into such form except by themselves in collaboration with their colleagues. Thus, old curricula remain, annually becoming structurally more " concrete " but functionally less successful and some schools wait on, in agitated depression, for ready-made " concrete plans " which will never come. For this reason, we said[2] " to break the mould of the existing curriculum it may be necessary to start in Britain a new medical school "

As one means of solving our problems SCOTT[4] pleaded for restoration of the art of " great teaching " to its proper place. But the " great " teachers were largely engaged in teaching what was known, while we are now equally concerned with teaching the best attitude to what is not yet known. " He teaches best," said ALAN GREGG in 1953,[5] " who shows his students how to learn not what to think in 1953, but how to think and how to learn to think in that long stretch of days (ahead) till, let us say, the year 2000 " We agree, however, with SCOTT and with WILSON[6] that there is a great need for " teachers who take their responsibility as teachers as seriously as they take their research work or their clinical duties " We are particularly impressed, therefore, with the principles which, as SINCLAIR records, were kept in mind during the planning of the Perth curriculum "A series of weekly lunch-time meetings was instituted among the professors, and it is proposed to continue this most valuable practice indefinitely." "The second principle was that the details of time-table arrangements or teaching methods must never obscure the all-important attitudes of both teachers and taught towards the process of becoming a doctor"

This augurs well for the future of Perth Meanwhile, in this country, our best hope seems to lie in the Association for the Study of Medical Education,[7] which will hold its first conference [8] on Sept 25 and 26 If it can draw together all the interested teachers from all disciplines and all schools, it will not only provide them with mutual strength and encouragement but will also enable them to work together to increase our knowledge of education The stimulus to progress thereby generated cannot be ignored it can produce that factual evidence of present weakness, and of the results of change, which alone will convince the faint-hearted, and the too easily satisfied, that change has to be made

Tropical Practice

MEDICINE in tropical climates has always been a challenging affair, and its enormous problems have attracted outstanding men Now that the perils of monsoon and insect have to some extent receded, doctors in the tropics are looking at matters which had previously been masked by the daily drama and, perhaps, by the traditional approach to scientific medicine From her wide experience, Dr CICELY WILLIAMS [9] believes that training in pædiatrics for the tropics is not as good as it should be—and we agree [10] Now, in this issue, Dr JOHN WRIGHT puts forward some good ideas for overcoming present deficiencies and for helping the tropical neophyte With increasing specialisation and complexity in Western medicine, training needs for the "home front" and for the tropics are always diverging The doctor in veldt or jungle has no second opinion, and to "pass the buck" may involve a long journey by bullock cart and an expense that the patient's family cannot afford The doctor's daily tasks may include drawing a tooth, removing a uterus, taking an X-ray (if he is lucky enough to have a machine), and fitting a new half-shaft to the hospital van-cum-ambulance Medicine of this calibre demands high skill and considerable mental stability

Among his proposals for meeting this challenge, Dr WRIGHT's most interesting suggestion is a year's "internship" in a teaching hospital at the place where a doctor intends to work This seems such good sense that we wonder why it was not introduced long ago there are still too few suitable institutions, of course, and perhaps the small number of doctors has made the "waste" of a year impossible But tropical medicine is not just a specialty, it is a complex of specialties, and the doctor in India will find himself dealing with a different set of problems in different circumstances and in a different culture from his colleague, say, in Africa or British Guiana—and therein lies the difficulty of teaching the subject thousands of miles from where the students will finally work It is a good idea, too, to ask tropical practitioners on furlough to help home-leave is still, happily, on the grand scale, and many of them would be pleased to share their experiences and earn a little extra money

Dr WRIGHT treads on emotionally insecure ground when he suggests that new countries should scale down the training of students to methods they can afford, but, as he points out, what is sauce for the British goose is not necessarily sauce for the tropical gander, and medical practice will improve by adaptation to local circumstances Dr WILLIAMS thought it wrong for developing countries to put emphasis on large Western-style institutions, and we believe that Western experts do a disservice if they encourage such Governments to start costly ventures of uncertain value Likewise, as Dr JOHN B GRANT has insisted,[11] the undergraduate medical curriculum in the tropics should be devised, not to reflect curricula in the U S A or the United Kingdom, but to train an "undifferentiated physician", competent to undertake general practice in his own community Obscure investigations, all-day operations, complicated treatments may be out of perspective when the average age of death is in the thirties and infant mortality is twenty times as great as in Britain This is not to say that research has no place in the tropics, but it should be devoted to the vast unsolved problems of epidemiology and nutrition and to the relationship of disease to the wide cultural differences throughout the world Many Western riddles might be solved if we knew the answers to the sort of questions that abound here Why is appendicitis so rare in some primitive rural communities? Why is disseminated sclerosis almost never seen in India? Why is syphilis so widespread in the tropics, yet affection of the central nervous system so rare? If the difference is due to "autotherapy" from attacks of malaria, does the pattern hold for malaria-immune hill areas? Facts emerging from careful work in the tropics could radically alter ways of life in many other countries

How should the doctor fit into this changing pattern of tropical practice? Hitherto, effort has centred round isolated overworked Government or mission hospitals, and it is tempting to follow a more thorough version of this plan But large-scale curative and preventive measures, though very necessary, are of slight value when unsupported by coordinated development projects touching many aspects of life—economic, eugenic, educational, technical, domestic, and (many would add) religious Such plans are proceeding in India on a heroic scale,[12] and the experience they are providing will be of the utmost interest to all who work in deprived countries In this scene, the "greater medical profession" includes experts in many social and technical subjects, and the doctor is little fitted by training for such comprehensive collaboration—another aspect, perhaps, which could be approached during a " tropical internship "

Learning

What is to be readily remembered must be taught without tears this moral is suggested by some recent comments of Dr Ritchie Russell [1] [2] on the physiology of learning and memory As befits a clinical neurologist, he has concerned himself primarily with human learning and he has emphasised the importance of encouraging in all educational endeavours " personal feelings of the optimal type ", since, as he says, " every memory seems to carry its own personal reaction or feeling " He also discusses the problem of innate versus acquired intellectual ability, and again his conclusion is encouraging in regard to the potential value of efficient instruction, for he leaves open the question of whether outstanding mental capacity is predominantly innate or acquired Educationists may find further incentive to their efforts in the work of Newman et al ,[3] who studied the relative contributions of heredity and environment in determining the performance in intelligence tests of identical twins Results suggested that the scores achieved by identical twins in the Stanford test are much affected by environment, since the divergence between these individuals, whose genetic make-up may be assumed to be very similar, is much greater when the siblings are separately reared than when they share a common post-natal background

Of course there are limits to what can be achieved by any educational method, and some anatomical observations are relevant Extremes of underdevelopment amounting to the congenital absence of the physical apparatus required for intricate mental processes are seen in anencephaly and severe porencephaly, and also in the so-far irreversible effects of an unfavourable " internal environment " during certain vital stages of cerebral maturation, as in the untreated cretin Apart from these, however, there is considerable variation of brain size, even in relation to body size, within the human race, and on the whole there seems to be a poor correlation between cerebral mass and intellectual brilliance It is true that of the (presumably complete) brains the weights of which were recorded by Lassek,[4] the smallest, which weighed 289 g , belonged to an adult mental defective, and the largest, of 2012 g , belonged to the celebrated Russian writer, Turgenev Nevertheless one quite normal man had a brain of 650 g , and the only anatomist in Lassek's list contributed merely 1198 g of cerebral tissue The possessor of the 650 g brain had a body-weight of 66 kg , which gives a brain to body-weight ratio of 1 105 as compared with the average human figure of 1 44 (The marmoset, incidentally, has a ratio of 1 27 and the whale of 1 8500) To be set against such static morphological data are the more dynamic observations on changes of weight and structure with age The relatively rapid increase in size of the human brain in the early years of life results in roughly a doubling of its weight between birth and the end of the first year, thereafter its mass increases at a diminishing rate until the age of about 25 More interesting perhaps are the changes after the 25th year Between the ages of 20 and 80 the brain loses some 10% of its weight, and Burns [5] estimates that during every day of a man's adult life several thousand grey cells must die It is obvious from a superficial consideration of localising signs in nervous diseases that adult cerebral neurones are not mutually equivalent, but the depopulation of the cerebrum on this scale is a challenging observation to those who have passed their second decade of life

In the experimental study of learning, the researches of Pavlov [6] on conditioned reflexes are fundamental work He demonstrated the possibility of associating a response such as salivation, which is a natural consequence of eating, with an unnatural stimulus such as the shining of a light Most of Pavlov's experiments were carried out upon dogs, which " learned " the new association after some twenty or so repetitions of the two stimuli, the natural and the unnatural, in combination It has since been shown by Boycott and Young [7] that a much more primitive creature, the octopus, is capable of being trained in a similar way Yet it is a far cry from the establishment of such relatively simple trains of association, based on repeated exposure to the same experience, to the capacity for rapid assimilation of knowledge displayed by such historic figures as Lord Macaulay, who, it seems, would take in at a glance long passages of print which he could later repeat almost verbatim, or Dr Samuel Johnson who was said never to have forgotten anything he read Conditioned reflexes of the simple pavlovian type can apparently be established in decorticate dogs, but more complicated reflexes which involve the addition to the response of a second normally " voluntary " action, such as movement of a limb, are attainable, in dogs, only in the presence of the cerebral cortex In rats, however, there is evidence that " learnt " reactions to visual stimuli can be effected through subcortical mechanisms after—but only after—the visual cortex has been removed It seems clear from the work of the ethologists that in certain animals remarkably complex patterns of behaviour must be regarded as innate or instinctive Such patterns can be evoked by rather simple triggers once the natural triggers are identified Thus, Tinbergen [8] has provoked aggressive conduct in the stickleback using a suitably coloured dummy, and Lorenz,[9] after recognising and imitating the essential features of maternal behaviour in ducks, was able to impose himself successfully as a mother substitute upon a brood of ducklings which reacted almost as demonstratively to him as to their natural matriarch It is true that in these instances the natural stimulus was mimicked, but it seems likely that artificial stimuli might be superimposed by appropriate pavlovian conditioning.

On the other hand, animals can acquire high competence in certain tricks, and dogs, parrots, and circus animals have made substantial reputations in this way Stereotyped exercises of this general kind have been much used in the study of learning, particularly in rats and monkeys, and it is tempting to physiologists to interpret such acquired skills, which improve with practice, as being mediated by the development of preferentially excitable nervous links connecting the receptor and effector organs, by analogy with the heightening of excitability in spinal neurones which, as shown by ECCLES and MCINTYRE,[10] can be induced under suitably chosen conditions The analogy is imperfect, however, and any simple concept of a unique nervous pathway underlying such learnt skills is made unacceptable by the experiments of LASHLEY[11] He showed by excision of different portions of the cerebral cortex of trained animals that the postoperative disability in performance of the learnt tasks was proportional to the extent rather than the location of the cortical damage This conclusion is rather at variance with some clinical data relating loss of memory to localised cerebral lesions Thus, at first sight it appears to conflict with PENFIELD's[12] finding that quite detailed and reproducible memories can be elicited by stimulation at operation of a very small area of human cerebral cortex But PENFIELD himself is inclined to interpret his results in terms of activation of some region, other than the stimulated cortex, which is the location of what he calls the "actual ganglionic patterns of experience"

The psychological approach to the elucidation of learning processes has evoked many theories of learning (HILGARD[13] lists ten) Certainly, any comprehensive theory should take into account information obtained by psychological techniques of investigation, and every satisfactory psychological theory of learning should have an acceptable physiological substratum, since, as LORENZ[14] has emphasised, there can be no psychological process which does not have its physiological correlate

In the understanding of the learning process much remains to be explored and hence many advances are to be expected That should prove a happy augury for those embarking on the learning of physiology—provided active curiosity rather than passive receptivity is to qualify as an "optimal feeling" in Dr RITCHIE RUSSELL's sense of the term

The Student Apprentice

THE rise of the great teaching institutions based on universities and hospitals saw the decline of the apprenticeship system The humanity of medicine may have suffered from this change, for institutional teaching cannot replace the personal understanding given by a sympathetic teacher to one or two disciples The swing of the pendulum towards institutional teaching was the inevitable result of scientific advances, but the return swing is equally inevitable and we can already detect its beginning

Since its foundation the College of General Practitioners has pointed out that, though disease has for generations received almost exclusive attention in the formal medical curriculum, the patient is equally worthy of the consideration and respect of the medical student. Between the wars it was exceptional for the student to meet the general practitioner and his work, though in Edinburgh students could include dispensary practice in their experience The belief may have been that general practice need not be taught because it was no more than the application in independent practice of all the knowledge the student had gained in hospital Such a view could well take root in the corporate mind of a congeries of specialist teachers, none having been in general practice Or it may have been argued that an activity of so wide a scope could not be taught, and that any attempt to teach it was doomed to failure This view has not been accepted by the College of General Practitioners, whose undergraduate education committee has lately published[1] a summary of its activities and a statement of its policy—a document which will be welcomed by deans of medical schools, to whom it is primarily addressed The structure of the college is such that, with few exceptions, each of its faculties has, in its region, a university with a medical school, and all encouragement is given to the university to seek the help of the undergraduate education committee of the faculty It is not the function of the college to proffer unsolicited advice, but these committees can work closely and profitably with undergraduate deans The college believes that the benefits of an early introduction to general practice (such as are described by Mr BERZON on p 441) should not be confined to those who intend to make this their vocation, and that those who look towards a consultant career should certainly share them Some, even within the universities, would go further and say that no aspirant to a specialty of any kind should be allowed to forgo such an introduction

In support of the undergraduate teaching schemes which are being increasingly adopted by the medical schools themselves,[2] the college offers to arrange attachment of final-year students to general practitioners on an undergraduate teaching register This register is based on a questionary circulated to members of the college in 1957, and contains the names and addresses, with details of qualifications and experience, of over 1000 general practitioners who have indicated their willingness to accept students in their practices Deans of the medical schools will want to know that this register is to be kept up to date Many of those named in it will already be known to the universities as teachers, and may already be taking students The remainder, by inclusion in the college's list, carry by implication the college's recommendation Willingness to accept a student in a practice usually presupposes high standards —at least in the eyes of the doctor himself—but from among a list of volunteers there may be some less suitable than others The undergraduate education committee of the college will do well to scrutinise future applications from doctors to join the register, to ensure that those admitted are able to maintain standards that will satisfy a critical and possibly sceptical dean

[2] *Lancet*, 1957, ii, 415

How far student teaching in the home and in the surgery can be supported by general-practitioner teaching in the wards and lecture-rooms remains to be seen And there is also the possibility of extending present arrangements to give the student much greater responsibility (as is done in Boston under the scheme described by Mr HASS on p 442) Medical schools and universities will continue to give thought to such developments, for, as Dr LOGAN says earlier in this issue, "to farm students out to general practitioners for short periods is hardly enough" If it is accepted, however, that the general practitioner can help to draw many divergent specialties together and present them as a coherent whole to the medical student, then a department of general practice in each university is the next logical step Such departments could, among other things, undertake the research into general practice that Dr LOGAN asks for

Annotations

SOCIOLOGY OF MEDICAL EDUCATION

A STUDY of the sociology of medical education was begun some years ago by the Bureau of Applied Social Research of Columbia University (with the aid of the Commonwealth Foundation), and in this inquiry students and staff in the medical schools of Cornell University, the University of Pennsylvania, and Western Reserve University collaborated A first set of reports has been published under the title *The Student Physician*[1] and makes a book unique in the literature of medical education It is not concerned with "what is being taught, what should be taught and how it might most effectively be taught", but with the process of education in the medical school, and "the ways in which its social structure, like that of other organisations, largely forms the behaviour of its members and so affects the makings of the medical man" The aim has been to discover to what extent and through what processes the medical school shapes the professional self of the student, so that he comes "to think, feel and act like a doctor" Prof Robert Merton, of Columbia, who has been mainly responsible for directing the investigation, writes "Students learn not only from precept, or even from deliberate example, they also learn—and it may often be, most enduringly learn—from sustained involvement in that society of medical staff, fellow students and patients which makes up the medical school as a social organisation" It is the basic values of their professional life which are learnt in this way

This work has produced a large mass of information on a subject never previously investigated Rightly, therefore, no attempt has been made to give significance to any of it Nor can any of it be lifted from its American context and applied to British students and schools This pioneer enterprise, however, is a stimulus from which many can profit by examining its methods, even though in Professor Merton's words they "do not meet the strict requirements of experimental enquiry" They are "more nearly like methodical studies in natural history and ecology than like laboratory experiments," but they are far removed from casual impressions

In this country it is now accepted that medical education must be studied In medicine we are committed to the reduction of empiricism by scientific inquiry, and few now persist in the view that a similar outlook is inappropriate to medical education This dwindling opposition may itself need methodical inquiry, for "institutional procedures, once functional for their time and place, engage the loyalties of men involved in them These men, able to point to the undoubted accomplishments of the past and confident that their motives are above suspicion, find new arrangements unsettling and excessively unsure When the relative merits of competing alternatives are difficult to demonstrate, as they commonly are in establishing or modifying social institutions, the resistance to change is all the more intense" This resistance can be broken down only by increasing our knowledge of the processes of medical education.

The value of *The Student Physician* lies not in its information about the reactions of American students but in its description of the application of sociological research to education It illustrates how this newest method of inquiry can reveal and liberate the traditions of medicine as a force which can powerfully augment appropriate changes in medical education For "in Medicine, the great tradition is typically that associated with celebrated physicians of the past, with those who have shown a capacity to move forward when most of their colleagues were satisfied to let things remain as they were" We can recollect the words of John Morgan, written in 1765 and quoted in this book "the longer we follow any faulty system, the more difficult we find the task to break through the shackles of it, even when it enslaves us to our greatest detriment"

TEXTBOOKS A NEW STYLE?

ON trial for making a bonfire of the books of ancient scholars, Paracelsus called them a pack of lies, but if he had still been at his burning today he could hardly have made that an excuse for consigning the modern medical textbook to the flames It is not in their veracity but in their influence on the students' sense of proportion that some undergraduate textbooks seem to err The practice of medicine and surgery is still overwhelmingly based on informed guesswork, on an appreciation of probabilities The experienced doctor's greatest asset (what strikes his mystified juniors as his clinical "flair") is his sense of relative frequencies It is a sense that grows slowly, and it is retarded by the too easily acquired habit of thinking in terms of lists And lists are too prominent in many textbooks One or two skilful writers have been able to convey that all items on their lists do not have the same value, but that is an unusual quality, and it is the list which encourages the student to think of Whipple's disease before appendicitis and of lymphogranuloma inguinale before inguinal hernia We might go so far as to say that the undergraduate textbook which claims to be "comprehensive " should have this claim thoroughly investigated· only after it has been found correct should it be destroyed

[1] The Student Physician Edited by ROBERT K MERTON, GEORGE READER, and PATRICIA L KENDALL A Commonwealth Fund Book Cambridge, Mass Harvard University Press London Oxford University Press 1957 Pp 360 40s

While similarly engaged last year [1] in the popular sport of belabouring the textbook, we suggested that there was a place for the book which made no claim to completeness but described essentials And we wondered whether a publisher would care to issue a cheaper " utility " edition of a textbook to compare its sales with those of the standard edition We are glad to welcome, therefore, *An Introduction to Surgery*,[2] edited by Mr David Patey, and published (in two styles of binding) by Lloyd-Luke Mr Patey and his colleagues introduce surgery without tears and with many positive merits Among the pitfalls they have avoided there are the 1000 and more pages which the book does *not* contain it has now been proved that 224 pages of carefully selected text can suffice for an introduction to surgery Almost half the book is devoted to general principles and not only the familiar but glimpses of the unknown beyond the limits of present knowledge The local reactions to injury are divided into intracellular and extracellular " The intracellular reactions are obviously of fundamental importance, but unfortunately we know very little about them At present, therefore, we can only note their potential importance " The temptation to include here some insignificant detail of the intracellular reaction about which something *is* known must have been strong The second section deals with methods of examination it is no less good, merely more conventional Some practical procedures are then described, and finally an excellent glossary will be a boon to students who have allowed the time when elementary questions can be asked without embarrassment to slip by without asking them Our only fear is that the book may prove so valuable that students will want to possess it in the more robust binding, so that the result of the two-binding experiment may be misleading

EPONYMS IN MEDICINE

THE clinical teacher who asks his class to write down the surnames of the men who described Colles' fracture, Pott's paraplegia, and Perthes' disease is likely to be greeted with exclamations of derision But there is a deceptive simplicity about the question, and experience has shown that an inquisitor who receives even one paper with all three names faultlessly spelt can pride himself on having a class of more than average alertness—or one (dare we hope) that reads *The Lancet* with commendable diligence

The creased brows and the erratic guesses about the position of the apostrophes may prompt some thoughts upon the advisability of using eponyms at all in modern medicine Some there are which will never be supplanted, by reason of the admirable precision, and the enduring style, of those who created them Hippocrates, for instance, describing the " sharp nose, hollow eyes and collapsed temples " of such ominous significance in acute infections, or Kussmaul with his " stuporous condition and the great loud breathing " Others will endure, if only because their use saves so much time in writing histories (Weber-Christian disease is, admittedly, not an entity which is diagnosed every day of the week, but when it is encountered it is more easily described as such than as " relapsing febrile nodular non-suppurative panniculitis ") ·

It is given to few men to describe a syndrome so completely that none of their colleagues can subsequently add anything to their work And when their colleagues do so, that student's nightmare, the hyphenated eponym, is likely to result In a comprehensive and erudite article, Shapiro [1] has lately discussed this aspect of medical terminology and its multiple incongruities Sometimes, and most logically, a hyphen joins the names of two workers who described a disease simultaneously—as did Morquio and Brailsford, writing of their osteodystrophy (The Montevidean wrote in a French journal, the Englishman in an American one, but both papers were published in 1929) On the other hand, nineteen years separated Stokes' description of " repeated cerebral attacks " from that by his colleague, Adams, who succeeded him to the same professorial chair in Dublin

" Occasionally, the hyphens become multiple, more years pass, and others act as midwives-in-eponymy " Shapiro cites the case of the Laurence-Moon-Biedl syndrome, and says that " to be just to all involved, this familial idiocy should be idiotically designated the syndrome of Laurence-Moon-Bardet-Biedl-Solis-Cohen-Weiss " There is one further pitfall about hyphens their use does not always indicate more than one author Krafft-Ebing, Brown-Séquard, and Albers-Schonberg were individuals, and not limited companies So were Austin Flint, Argyll Robertson, and Bence Jones—but *their* shades would not be gratified by hyphenation

One field of eponymous fame remains which few will dispute, and to which none will aspire If a man not only describes a disease for the first time but also does so from his personal experience, it is hard to contend his claim to have his name associated with it thenceforward Julius Thomsen has such a claim, for, though Leyden had written of amyotonia congenita two years earlier, Thomsen's description of five cases, published in 1876, has endured because the patients were himself and his four sons Similarly, Hillard's lupus stands uniquely in the name-strewn battlefield of dermatological nosology And whoever talks of a rickettsial infection pays tribute to an investigator who died of one in Mexico (On the other hand, contrary to the legend perpetuated in many histories, Percivall Pott did not sustain a fracture-dislocation of his ankle)

Despite all the contention their use involves (and all the grey hairs they bring to editors and type-setters), these titles cannot lightly be discarded They are part of the living tradition of medicine But when they are used, contributors and editors must strive to ensure that they are placed in a correct context and accurately rendered It is a poor act of homage that spells a man's title wrongly, or ascribes to him a different condition from that he described For how often must such thoughtlessness cause some great forebear of medicine to stir restlessly in his grave and exclaim, with poor Hamlet, " O good Horatio, what a wounded name, things standing thus unknown, shall live behind me! "

The Wider World

EDUCATION FOR THE TROPICS

JOHN WRIGHT
M.B. Leeds, F.R.C.S.
LATE MEDICAL OFFICER, METHODIST MISSION HOSPITAL,
ILESHA, WESTERN NIGERIA

> "We should ask ourselves from time to time whether we are giving these friends from abroad what they need, and whether we are giving it well enough." [1]

IN her excellent Milroy lectures,[2] Dr Cicely Williams touched upon some of the difficulties which stand in the way of successfully developing health services in the tropics, and discussed the adjustments which clinicians must make when they begin to practise in such countries.

When one steps aside from the County Ground of our own sophisticated medical service on to the Village Green of tropical practice, the truth of what she has written is all too evident, and its relevance is undeniable. What are at present "underdeveloped areas" will, within a generation or two, have an incalculable impact on the rest of the world, and the contribution which Western culture can make now to their health and development will have an equally great effect in moulding their future attitudes to us. To put it at its lowest, and without "taking an over rosy view of the sociological importance of doctors", the problems of rural health in the tropics are not ones which, in our own long-term interests, we can afford to be complacent about. They have about them an urgency which we, in our society, find hard to appreciate.

Certainly a real pride is permissible in the contributions which Britain has made, particularly in the last half-century, to the health of such underdeveloped countries. No-one can belittle the achievements of epidemic control, or the single-minded enthusiasm and selfless energy that has gone into them. Even so, our medical practice in the tropics has often been a matter in the past of the "microscope, the pill, and the injection", and we have tried sometimes to impose on developing tropical countries our own particular pattern of medical practice, sidestepping all the social background which the latter implies. Many British doctors, trained in British schools and set in the tropics, would confess at least to occasional doubts as to whether they were achieving anything solid, working on the pattern of English practice. In his first vivid impressions, professional life to him is too much like the treadmill: on the one hand, the body of disease is overwhelming, and the mortality (especially among the very young) is fantastic; on the other hand, the economic and technical resources to which he has access are desperately limited, and practice is constantly walled about with a social heritage he does not understand and cannot counter.

But such doubts are soon cushioned. It cannot be otherwise when each working day starts at 8 A.M., finishes 10, 12, or 14 hours later, confronts the doctor with patients in hundreds rather than dozens, and showers a kaleidoscopic variety of disease on him such as he has never had to tackle before. It is not difficult to understand how easily he comes to regard his hospital practice as his raison-d'être, and has few energies left for the wider view.

This is, moreover, an attitude in which he has been implicitly encouraged during his student or postgraduate days in England. His concern is sickness, not health, his duty not prevention but cure, and he has been encouraged to believe that the more competent his judgment grows the more restricted in range it must necessarily become. Striving for ever-increasing technical mastery of his own specialty, he seeks (quite rightly) the advice of specialists outside his own contracting field more and more. His eyes become turned to the minutiæ and he becomes more and more concerned with the technical intricacies of his own subject.

Out of this background, implied or developed, he is lifted, set down in tropical practice, and expected to be able to survey the needs of rural health successfully. To say the least it is an ill preparation that he has been given.

At the core of the situation, therefore, lies the problem of medical education—of how the present education of doctors for the tropics can be so altered as to provide both European and African doctors who are able to work more efficiently to their needs. And if it seems presumptuous for one who has never worked in a tropical teaching centre to reflect on medical education the only justification is that at least he has done so from a rural hospital on the Village Green.

The Village Green

This particular village green lies in a belt of tropical forest some 10° north of the equator. Its thirty acres are set on the top of some rising ground at the edge of a town of some 75,000 people. As in many of the bigger pitches, those amenities which are held by some to be indispensable to the playing of decent cricket are now on their way. In the past few years many hundreds of miles of new tarmac road have been laid, with a rising toll of fracture, laceration, and death. Electricity arrived some time ago in the overhead cables, and is altering the sleeping habits of the town. "Rediffusion" brings Mozart and the cricket scores into every backstreet, and some years ago water flowed into the town for the first time through pipes, bringing (for its first few months) such a wave of diarrhœa as the local wells had never been able to produce.

The Village Green is certainly changing with remarkable speed, and it is easy for the outsider to be misled by its rapidly changing new look. Rural society, however, is much the same the whole world over, conservative to a degree, and with a wealth of lore that runs strongly below the surface, no matter how the patterns on the surface change. And for all the water pipes, the pylons, and the new roads the Village Green still remains very much the Village Green.

The pitch here has a growing history, for it is something over 40 years since the first doctor and his wife arrived—in the days when the bicycle was still a curiosity, when they had to face many days of hard travel along narrow "bush paths", and when every device was used locally to discredit their work. With these two the game began, the doctor's readiness for each day's play being signified by the ringing of a bell which still stands on the present pitch. He and his wife are still vividly remembered by a few of the older inhabitants, through whom we, in our turn, are reminded of the days before cricket became established.

We are, therefore, perhaps more fortunate than some in being, through the continuity of our history, conscious of how close we are in time to the unregenerate days of Non-Cricket. And this is perhaps more important than it might appear, since attitudes are not to be changed in a matter of a generation, they must be taken into account in shaping tactics and strategy. The other important reason for mentioning history is that, since this particular club has always had to be more or less self-supporting, progress from the start has been by struggle and often by improvisation—i e , learning to make new uses for the resources at hand, and learning to do without what you cannot afford And this is, as I shall suggest later, an attitude which must guide the conduct of cricket in such places if it is to be played for a final win

---

[1] *Lancet*, 1958, i, 951.

[2] Williams, C. D. *ibid* pp. 863, 919.

Since those days, however, the pitch has been twice moved, and greatly expanded and improved and now, perhaps, as a result of this growth and *prosperity faces* a new danger—the danger of trying to become an accurate small-scale replica of a county ground at home, using the same techniques and methods We are faced in fact with the danger of forgetting that the problems still differ as much from those in England as *they did in earlier days* And this danger faces neighbouring clubs as well

The Setting and its Problems

Some more interesting aspects of the game, however, must affect our attitude to medical education, and the way in which it is planned

What are We to Teach About ?

Leaving aside for the moment the revolution in social thinking which has to be undertaken by any doctor when he moves from a European background into the tropics, there is first the technical content of any curriculum In a setting in which the incidence of particular disease is topsy-turvy by comparison with what he has known in which the age-mortality curves are all awry in which preventable malnutrition is the scourge of childhood and in which the *natural history of any disease is very often* quite different to the same disease *in Europe, it is* plainly unsound to expect the curriculum of a Western medical school to be adequate for those who are going to spend their working days in the tropics.

There is little point in instilling the minutiæ of appendicitis, perforated duodenal ulcer, carcinoma of the rectum or lung, when these conditions are *rarely seen It is* misleading to teach that intussusception is an ileal disease affecting the infant and presenting with a certain symptom-complex, when in fact it is a cæcal disease affecting adults and presenting with quite a different picture It is dangerous to imply that the bottle is a possible substitute *for the breast when it is virtually out of the* reach of the vast majority of the population

It is equally misleading to teach that the diagnosis and management of chronic peptic ulcer depends in the first place on radiology, when it is commonly of a type very difficult to *display radiologically,* and the *opportune moment for* laparotomy has to be judged as much by social factors that are quite unknown to European medicine It is dangerous to paint rupture of the uterus as a rare condition best treated by hysterectomy, when it is a comparatively common one best treated by suture

Such examples could be multiplied indefinitely but the conclusion to be drawn is obvious It is not enough merely to add a course of " tropical medicine " on to the present form which medical training takes there must be some attempt instead to teach of " medicine in the tropics "

Tactics of Medical Practice

But such things are perhaps only the beginning of the doctor's metamorphosis , reorientations are needed towards the *practice of medicine which go* far beyond this, and which require the doctor to escape from the bonds of habits to which he became accustomed when he was a student

In the matter of techniques, *for* example

The *setting is one of rural life* the background one of often-superstitious custom The home teams evolved their rules for their own version of the game long before any European arrived and though many of their old techniques may be positively harmful, yet some are admirably adapted to the local resources, being as effective as our own new-fangled (and expensive) *methods* They are not to be automatically rejected (as *they* often are), and doctors must remind *themselves that there* can be no rule-of-thumb approach to the use of techniques

The carefully boiled leaf, so much affected in the dressings of sores, need not automatically be *replaced* by the imported and expensive bandage before progress is made and while it may be amply justified to insist on retaining in toto the sterile-cutting strokes of the surgically trained batsmen (with all the expensive *paraphernalia* which these presuppose), it *may be* equally wrong to *lift* a *premature* baby from the warmth of its mother's back and set *it in* an *incubator*

Again, the economic resources of most tropical countries are severely limited, and we offer nothing but a gratuitous and unnecessary discouragement to self-help if we misguidedly suggest that good medicine can only be practised where there are expensive facilities and techniques It may seem quite logical to us, for instance, to treat an œdematous *protein-deficient child* with a tin of skimmed milk, or ' Casilan ' but if we give the impression by so doing that these are the only weapons for the purpose, rather than preventing the condition with a diet of fish or beans (or whatever other protein happens to be local and cheap) we are in the long run doing more harm than good

Strategy

But important as reorientations of curriculum and tactics *may* be, even more important is our attitude to strategy For what we conceive to be the necessary long-term strategy determines not only what sort of student we *aim to get for medical* practice in the tropics but also how *we educate him—in the widest sense of that term*

In this country, against a backcloth of gradually developed social services we can set a highly developed preventive and public-health service Though it is obviously one of the keystones of our health programme, it is also the one which most of us forget about, or take for granted, most easily With these preventive services established, and in a country where *population density* is high and distances short, we can very satisfactorily divide clinicians into the general practitioners and the consultants, grouping around the latter a host of technical advisers and expensive facilities

There is one other very relevant factor on which we can also rely in this country And that is that every child, almost from the age of five upward, is tutored directly or indirectly in the sciences from which Medicine stems Even therefore if he never practises Medicine he understands its roots Things, of course, are very different in the tropics

In the tropics, however, there can seldom be such division of labour and each clinician must, ideally, have in himself therefore the elements of all—the attitudes if not the technical proficiency There is no comparable background *of preventive services or of child education* to fall back on, no such wealth of technical advice or expensive facilities, the distances are vast, the population density low, the setting rural, not urban or industrial In such a setting to model *medical* practice on the English pattern (with its sharp distinctions between those in hospital and those outside, between the specialist and the G P) is very bad strategy Rather must each doctor be conversant with the disciplines and attitudes of all the doctor-categories we know at home, and his strategy must be enlarged to include the strategy of them all—the educational, the preventive, and the social, as well as the more purely clinical skills he is taught in *his formal medical* course as a student

The Implications

From this background certain conclusions seem to follow I speak, of course, only for what I have seen in West Africa, and the conclusions may not be valid for other parts of the tropics—though I suspect that they are

Adaptation of Practice

What is urgently needed is a great deal of careful thought in adapting European medical practice to the local scene Tactically this involves the willingness to adapt methods of practice already learned to those which the country can afford and which are effective This in itself involves a good deal more imagination and understanding than many people are willing to admit And often there may be a good deal of very understandable local sensitivity on this point, especially when it comes to the training of students The feeling, that "to adapt methods of practice already learned to those which are effective and which the country can afford" may imply to some that a second best is being fobbed off on the local students Nothing of the sort is, of course, being attempted The techniques we learn, the methods we use, and the attitudes we try to inculcate in British teaching *may* be as unsuitable as overcoats to a tropical community And in our anxiety to establish our good faith we must be careful that we do not go to the opposite extreme of trying to transplant all the detailed paraphernalia of a British teaching hospital holus bolus into the tropics

Strategy

In a country where the main causes of illness and death are infective and nutritional, health education, preventive medicine, and a real understanding of the health problems of traditional rural life are at least as important as an efficient curative service But if these measures are to be effectively applied at all, they must depend for their prosecution on rural medical officers liberally equipped with the necessary imagination and energy They cannot depend on centralised administration for their expansion It is true, of course, that as independence grows, the strategy of medical services is controlled more and more by politics outside the doctors' control, but, nevertheless, the whole framework so imposed is moulded by those who work it

Training of Doctors

The inescapable conclusion, therefore, is that the training of doctors for such countries must be redesigned Simple arithmetic shows that an adequate supply of doctors to deal with the needs of tropical countries will depend for the foreseeable future on Western help in their training Thus, in West Africa, for instance, the only English-speaking university with a medical faculty is designed to take up to 50 students a year If all these students pass their examinations without fail, and if there is no "wastage", and if each of them were to practice for 30 years within Nigeria alone, the maximum force of doctors provided for is thus 1500

If the present population of Nigeria alone (estimated at about 30 million) were to remain static, and all doctors go into clinical rather than into administrative practice, this would therefore give a proportion of 1 doctor to every 20,000 of population—and this in a country where distances are vast compared with Great Britain

An adequate medical service, therefore, cannot for many years depend solely on African doctors trained in Africa, but will have to include both European doctors and African doctors trained in Europe With its wealth of means, too, Europe will necessarily dominate the postgraduate training scene. New thought must be given to these groups, and their training redesigned.

Firstly, in its technical content, to rebalance teaching with the countries' disease patterns in mind This is not just a matter of the altered incidence of disease, but, more important, of natural history Such conditions, for example, as pulmonary tuberculosis, toxæmia of pregnancy, intussusception, measles, and peptic ulcer are simply not the diseases that we know by those names Much of the pattern of disease is in fact still obscure and waits patient observation and systematic recording A pattern, however, of which enough is known to make a start on teaching students and postgraduates

Secondly (and much more important), the education of doctors must be redesigned to develop new attitudes not relevant to European medical practice Of course it is important that the tropical doctor should be taught something of tropical infections and their vectors, but there are essential reorientations that go far beyond this and the student must escape from the past obsession of Tropical Medicine with microscopes, which has dogged him for so long Instead, he must be given something of the economic, social, and cultural setting in which he is to practise Effective medical practice in the tropics depends largely on how far he is able to adjust himself to this new setting It is not for the many, but the few mental pliability, imagination (rather than erudition), a capacity for improvisation, and considerable gifts of "sympathy" (in its exact sense) are the qualities most needed

Some Suggestions

The upkeep of doctors is an expensive item in the economy of any country What can be done to make both the pre- and post-graduate training of doctors more relevant to their tropical practice ?

In most British universities only a tiny proportion of students come from, or go to, tropical countries and it is obviously not practicable to alter the content and method of teaching in an ordinary degree course for these few On the other hand, by conforming to the pattern designed for British students who will practise in Britain, their training as it is at present leaves overseas students frankly unprepared either in character or technique to deal with what will face them

For the Overseas Student

The problem can in part be solved by a year's internship in a tropical teaching hospital, during which the newly qualified houseman has time and opportunity to adjust himself to the altered surroundings of his practice The value of such a year will obviously depend both on the capabilities of the individual concerned and on the provisions made by the teaching staff for his encouragement and adaptation Here is a challenge as well as a great opportunity to the tropical universities If the internship period is merely conducted on lines familiar in Britain, it will fail If it sets out, instead, to provoke the imagination, and lays emphasis on the social setting and natural history of the country's disease, it may succeed

Even so, however, the tropical teaching hospitals cannot hope to have sufficient appointments for all the graduates available and by their very nature are not entirely the best place to teach the implications of rural health In order, therefore, to expand their capacity, and to achieve a valuable balance in their postgraduate teaching, such teaching hospitals might perhaps consider the setting up of an Institute of Medicine attached to the teaching hospital but with a number of surrounding affiliated rural hospitals and dispensaries (The valid prerequisites which such hospitals and dispensaries should possess in order to qualify for "recognition" as part of the teaching body would in themselves form an interesting contrast to those demanded in this country) Such an institute would aim to set before both local and expatriate doctors the readjustments which are required for fruitful practice, and give them some experience of rural medicine in the affiliated hospitals The rural hospital, as well as the student would gain greatly by such an arrangement

For Other Graduates

Even then, however, there will be many students from abroad who have to do their internships in Britain, and so will British students who later elect to go into the Colonial Service For these

(*a*) Some similar course of medicine in the tropics (rather than Tropical Medicine) might well be provided This perhaps ought to be frankly freed from the dictates of a diploma curriculum, and concentrate instead on the wider view of medical practice in tropical countries (Or it might include some such "second paper" as suggested in a *Lancet* annotation[1]) There is a growing body of clinicians experienced in tropical practice who might be drawn upon to help, during their periods of home leave in Britain, with such a course

(*b*) To extend the body of clinicians with insight into the conditions of tropical medical practice, exchange systems between the senior departmental staff of individual British universities and their tropical counterparts might most valuably be extended But such experience would only be of value if the period of secondment were sufficiently long, and if, by spending a major part of it in rural centres, there was opportunity for grasping the basic health problems of the country

The tropical teaching centres would not be the only ones to gain by such increased interchange of doctors

Specialist Training

By both British and tropical postgraduate schools it should be recognised that there are some specialties more urgently needed than others In countries in which the "infant" mortality is in the region of 300–400 per 1000 within the first 5 years of life, where malnutrition forms the backcloth against which most disease patterns in children are played out, where the patterns of "normal child" development are often yet uncharted, the pædiatrician stands easily at the top of specialist requirements And as Prof Richard Ellis has pointed out,[3] some postgraduate training in pædiatrics should be provided for every doctor who seriously intends to practise in the tropics

This again involves a shift in emphasis quite foreign to the traditions of practice in this country

Conclusion

Since World War II, many have become more conscious of the cultural and educational role which, by its unique nature, the Commonwealth is superbly placed to assume Within this role the adaptation and applying of our heritage of medicine is one of our obvious opportunities

In this age of mass-production and quick results we are perhaps more prone than ever to see the solution of health problems in the tropics in terms of mass programmes of immunisation, suppressives, injections, free milk, insecticidal spraying, and so forth Such things are invaluable, and it is not to decry them to say that they are inadequate to the whole task The basic problems of health are still largely social, to be solved at community, rather than at mass, levels, and to be solved by doctors whose training is not only sufficiently catholic for the task but is also designed to develop the highest levels of adaptability

As Dr Williams wisely remarks, "It is not the scientific knowledge that is lacking, it is the will to give ade[illegible]ing to the necessary medical personnel"

[illegible] R. W. H. Personal communication, 1953

In England Now

A Running Commentary by Peripatetic Correspondents

I MAY not look mechanically minded but at least I know how to work the tape-recorder That is more than Derek, my junior partner, can say, either on or off the record

I stayed behind on Friday afternoon to dictate half a dozen reports and letters into the thing, ready for Sylvia to type on Saturday morning It was a pleasant weekend down on the river, just the sort of weather to leave the junior partner and our secretary to hold the fort in town If I do not start taking it easy now all those years of grinding away will have been wasted For all I know a coronary may be just around the corner

I got back to town with a sunburnt neck and some nice trout in the back of the car The next move was to find someone to tell it to. The surgery was empty so was Sylvia's cubbyhole Just a note on my desk to say that Derek had rather a lot of visits to make, and Sylvia was off with a sore throat I looked around for the letters to sign they were usually put out on the blotter The appointments would have to go out by the midday post or be telephoned instead The river had washed all the details from my memory, so I turned to the tape-recorder and switched it on There were the nasal overtones I reluctantly accepted as mine, droning out the weary tale of Mrs Green's low backache and frigidity We had just recapped about her coccyx when there was a click The spools went round in silence for a long time Then more clicks and rattles A voice that was unmistakably Derek's asked what the hell it had done now A panic soprano shrieked that darling had washed out all the rest of the old buffer's letters by twiddling that switch There was another ten seconds' silence, and then a duet of giggles Just as this was getting rather boring, the baritone suddenly asked who was going to tell the boss on Monday morning I was intrigued to know the answer myself Sylvia was to have a sore throat, and Derek would stay out all day until the old boy had got the fishing stories off his chest

SIR,—I am a French surgeon who makes his holiday in your so beautiful country and I borrow the pen of my landlady to write to you very quick because I see in your journal a letter which makes me very sad I think the three gentlemens which write this letter essay to kill in one foul swoop, as you say in your *language, so expressive, the sacred memory* of the illustrious Emile Coudé, of who I have the honour to be the grand nephew It is only last week ago when my assistant at the Salpêtrière say to me that there is a patient who cannot pass the water in the antechamber "The catheter" I cry. "Alas" responds he "I have already try" showing me the straight catheter of M Jaques "Imbecile! give me the catheter of my Uncle Coudé"—at last! the water she come and again a little more of glory is added to a name which the *Société* Internationale d'Urologie should revere but would make to fall into the mire "Over my dead corpse" I cry and sign myself

HERCULE COUDÉ

Coudé Rebent,
Blackpool sur-mer

The stars of the *Michelin Guide* have long been reverenced by gastronomes, motor-car drivers, and compilers of guides, so that there is now scarcely a single travel brochure which does not ape their infallibility by classifying its wares in the asterisk fashion This valuable aid has now spread to surgery, and a recent volume offers a *Michelin Guide* to fractures I see endless possibilities in the system, and the fashion will probably spread I look forward to a new edition of *Tidy*, starred unduly

- * Diseases you should have—of benefit to the physician and not much trouble to the patient
- ** Diseases best avoided—curable but expensive
- *** Diseases you should not have—inexpensive but incurable
- **** Recherché and distingué diseases, appealing to physicians only
- ***** Fatal diseases

Students' Guide

1958 1959

Medical Schools

At Oxford University there is at present no "quota" for medical students, the preclinical entry is about 75 per year, of whom about 12 may be women. Some of the colleges have formed themselves into groups for the purpose of considering applicants to read medicine and the following two extracts from the *Gazette*[1] refer to this arrangement

> "University, Balliol, Trinity, St Johns and Jesus Colleges and St Peter's Hall will act as a group in considering candidates for admission to read medicine Candidates should apply in the normal way to the college of their first choice, but will subsequently be asked if they wish to be considered at the same time by the other colleges The examination for these candidates will be held on 23–25 March, 1959"
>
> "Candidates for admission to any of the colleges Exeter, Oriel, Magdalen, Brasenose, Corpus Christi, Pembroke and Worcester Colleges should apply in the usual way, but will subsequently be asked if they wish to be considered also by the six other colleges named above If they do so wish, they will be allowed to place these in order of preference and their application will then be considered by each college in turn"

The entry to the clinical school is limited to 32 students a year, the majority coming from the preclinical departments of the university, but some coming from other universities These students may read for the degree of their own university, or if they have spent three years in an approved university, passed the equivalent of the Oxford 1st B M examination (organic chemistry, anatomy, physiology, and biochemistry), and taken an honours degree in the arts or sciences, for the Oxford B M degree

The new department for the Nuffield professor of surgery, Prof P R Allison, has been completed, and consists of twin theatres and laboratories, and two wards, all equipped to meet the professor's special requirements The new department for the Nuffield professor of clinical medicine, Prof L J Witts, is now almost completed Two new wards are in use and the research and teaching laboratories will be open shortly Plans have been prepared for new departments of anaesthetics biochemistry, and pathology, and a new outpatient block Even with the development of the new departments of teaching and research, together with the provision of an increased number of teaching beds, the university does not intend to increase the size of the clinical school Its aim will continue to be to provide the maximum amount of individual instruction and to give the student direct access to a large number of patients during his clinical training The tutorial system which has long been an integral part of the preclinical course at Oxford is continued throughout the clinical course This traditional tutorial system is one of the most valuable parts of the curriculum

At the University of Cambridge the number of candidates wishing to study medicine continues to exceed the number of places available and all college entries are subject to a university quota Two changes have been made in the regulations for the final M.B examination. The first relates to the period of clinical instruction in midwifery and gynæcology The regulations are amended so as to specify requirements of (*a*) six months' instead of three months' clinical training, (*b*) two months' instead of one month's residence in a maternity hospital, (*c*) instruction in antenatal and postnatal care Students who began their clinical training before Oct 1, 1956, however, will be allowed to proceed to the final M B examination on producing evidence satisfying the midwifery and gynæcology requirements previously in force The second change is designed to permit undergraduates who by the end of their second year's residence have obtained honours in the natural sciences tripos and have qualified in anatomy and physiology, and who wish to undertake a course of non-medical study during the third year in Cambridge, to take the final M B examination at the same time as their contemporaries who devote three years to the tripos and qualifying examinations The requirement that a candidate for either part of the final M B examination shall produce evidence of having completed five years of medical study has been amended to restrict the requirement to part II only of that examination The Cambridge medical student normally completes three of these five years as an undergraduate in residence and on Oct 1 following graduation begins clinical studies at a recognised hospital If, in the circumstances mentioned, the third year is devoted to non-medical study the student will begin hospital training with two years' medical study only to his credit, but will be allowed to count as part of his third year of medical study after graduation the period of three months during which he attends the long vacation course in elementary clinical methods He will then be able to take part I of the final M B (pathology and pharmacology) in the December of his third academical year at hospital and part II (medicine, surgery, and midwifery and gynæcology) in the following June, if he begins hospital training in the July immediately following his qualification for the B A degree either in his clinical school or by taking the long-vacation course in clinical methods in Cambridge

LONDON SCHOOLS

London University bears a different relation to its medical faculty from other universities, whereas they have one school of medicine each, London has twelve autonomous schools, each of which is closely linked with one of the teaching hospitals, as well as University, King's, and Queen Mary Colleges, all of which take medical students for some part of the preclinical course All the medical schools are now open to men and women students

At University College, which has the largest preclinical teaching and research staff in London, medical students taking the preclinical course come into close contact with students in other faculties, particularly with science students and research-workers who are specialising in anatomy, physiology, biochemistry, and pharmacology Every encouragement is given to students who pass the 2nd M B examination with credit to spend an extra year's study for the B SC (special) degree in anatomy or physiology Scholarships and exhibitions supplemented by the Ministry of Education are available for at least 12 students each year to take the B SC course This provides an admirable introduction to research methods and outlook, useful to the medical graduate in the clinical as well as the preclinical fields The first stage of the new biochemistry building in Gower Street came into use last autumn and the second stage will be ready later in the session The accommodation vacated by the biochemists will provide for the expansion of the physiology and pharmacology departments and the teaching and research resources of those departments will thereby be greatly strengthened Students accepted for the full medical course receive their clinical training at University College Hospital Medical School The dean of the faculty of medical sciences is Prof J Z Young

King's College provides courses for the 1st M B and 2nd M B examinations of the University of London for students who will be going on to King's College Hospital Medical School, St George's Hospital Medical School, or Westminster Medical School for their clinical studies No student may begin these preclinical courses who has not also been provisionally accepted by one of these hospitals for a clinical course King's College, with its faculties of arts, laws, natural science, engineering, and theology, provides the full activity of university life Applications for admission to the medical faculty in October, 1959, should be made at once, though applications may be considered up to the end of October, 1958 For admission in October, 1960, application between April and October, 1959, is advised

---

[1] *Oxford University Gazette*, no 2071, June 13, 1958

The arrangements made by the joint committee of QUEEN MARY COLLEGE and the London Hospital Medical College ensure that the teaching in physics, chemistry, and biology fits in closely with preclinical teaching Most of the places are taken by London Hospital men and women, but applications from students with other hospitals in view are considered During the 1957–58 session 51 first-year medical students passed through the departments

At UNIVERSITY COLLEGE HOSPITAL Medical School there have been no major excitements during the academic year 1957–58 The annexe to the hostel has continued to show its worth and now 103 students are able to live on medical-school premises U C H together with its sector hospital at St Pancras now has a minimum of 1000 beds, and the nearby St Pancras Hospital is being used more and more for the clinical teaching of undergraduates The new Rowland Hall is much used for both clinical lectures and social activities The hard tennis courts at St Pancras are also proving popular with students and nurses The sports ground and its new pavilion at Hendon, which is within thirty-five minutes of U C H, is being used more and more and already ideas for increasing the size of the ground are being explored The rebuilding of the dental hospital and school has not yet begun, but there are indications that a start will be made before March, 1959 Linked with the rebuilding of the Dental Hospital and School and the consequent increase in the number of students, plans are well forward for a new student House to provide ample accommodation for social activities This will replace the existing Medical Society's rooms in the medical school

The Medical College of ST BARTHOLOMEW'S HOSPITAL is housed in new buildings ideally situated in Charterhouse Square where, in addition to the College hall of residence, there is a gymnasium and tennis and squash courts The basic science departments of zoology and comparative anatomy, physics, biochemistry, anatomy, physiology, and pharmacology provide tuition for premedical and preclinical students in modern laboratory accommodation In addition there are research facilities for all these departments About 30 to 35 are accepted every year from Oxford and Cambridge as clinical students There is a number of entrance scholarships in arts and in science, and internal scholarships are offered to a limited number of suitable candidates taking an honours B SC course in the year after passing the examination in anatomy and physiology During their final year students have the opportunity of spending a few days with a general practitioner, and an adviser in general practice is on the staff of the college to help with these matters

CHARING CROSS HOSPITAL Medical School has during the past year acquired additional accommodation on the corner of Bedford Street and the Strand This space is being used to provide a more spacious library and a larger and more airy common-room for women students, writing-rooms, and other student amenities, as well as larger offices for the accounts staff The space thus released in the main building is being adapted to provide better facilities for teaching and research, and in particular to house a newly instituted professorial unit in obstetrics and gynæcology In addition to this new chair, readerships have been established in pharmacology and anatomy In the final examinations for the M B, B S degree all those who presented themselves for the examination in pathology last autumn were successful, and there was a similar 100% pass-rate in medicine in the spring On that occasion the only two honours awarded for surgery in the entire University were won by Charing Cross students

At ST GEORGE'S HOSPITAL Medical School the work of modernisation is going ahead rapidly The greater part of the new laboratory space and the club rooms will be complete by the beginning of the new academic year All the usual activities of the school have been carried on successfully despite the rebuilding operations, and the school looks forward to a return to normal working in October University approval has been given to the establishment of a chair in medicine and it is hoped that a professor will take office in July, 1959

At GUY'S HOSPITAL Medical School the two and a half years of preclinical studies are designed to prepare the student for the clinical work which will follow, and particularly for the eventual practice of medicine There is a close link between the medical school departments and the wards Oxford and Cambridge students are admitted for the three clinical years The aim at Guy's has always been to encourage responsibility from the moment the student enters the wards A three-monthly series of dresserships and clerkships are arranged in the general wards and in special departments so that students accept supervised responsibility for patients, and the emphasis is on bedside and outpatient teaching rather than organised lectures There are, however, lectures and demonstrations organised by the directors of the departments of surgery, medicine, obstetrics, pædiatrics, and anæsthetics in order to cover the whole curriculum Preregistration appointments are available for those newly qualified, and every encouragement is given to men of promise to obtain the higher degrees and diplomas It is a condition of entry to the medical school that students should join the Clubs' Union which covers all athletic and intellectual activities and includes membership of the Students' Club

At KING'S COLLEGE HOSPITAL Medical School, stage II of the new extension will be ready for occupation at the beginning of the Autumn term Stage I, which was completed in November, 1957, provides on the top floor accommodation for the new medical unit under the direction of Dr Clifford Hoyle, on the middle floor a practical pathology laboratory with places for 60 students, and on the ground floor additional rooms for student amenities, including offices for the *King's College Hospital Gazette* and the Clubs and Societies Union Stage II will contain on the top floor an extension to the department of chemical pathology consisting mainly of research laboratories The middle floor, again consisting mainly of research laboratories, will provide accommodation for the new surgical unit under the direction of Mr Harold Edwards On the ground floor there will be a clinical lecture theatre with 32 tiered seats Adjacent is a demonstration room which will be used for clinicopathological demonstrations where all aspects of selected diseases will be displayed for varying periods A student-health consulting-room with dressing-rooms, rooms for medical and surgical tutors, and a council room are also provided on this floor The new building will be formally opened on Nov 4 by Queen Elizabeth the Queen Mother, Chancellor of the University of London

The school admits clinical students for the London, Oxford, and Cambridge degrees The dental school provides courses for the B D S and L D S diplomas, and each year 50 medical and 25 dental students are admitted Students for the London degrees do their preclinical training at King's College London, where they have the advantage of associating with students of all faculties King's College Hospital has 550 beds (including Belgrave Hospital for Children) It is situated in the heart of a large residential area and it has one of the busiest outpatient departments in London with an ample supply of clinical material King's College Hall is within five minutes' walk, and it is still fairly easy to find comfortable lodgings in the vicinity The school has the use and clinical control of 200 medical, surgical, and obstetric beds for undergraduate teaching at nearby Dulwich Hospital, where the instruction is undertaken by consultants from King's College Hospital and by some of the consultants of Dulwich Hospital who have been appointed associate teachers in the medical school The arrangements whereby students gain first-hand experience of general practice have been extended At their discretion individual students can now spend up to one week in residence with a general practitioner, the school bearing a part of the cost

During the past year the number of applications at THE LONDON HOSPITAL Medical College has remained high Application can be made at any time after reaching the age of sixteen, or passing the General Certificate of Education at ordinary level, whichever is the earlier Applicants are interviewed as soon as possible after they apply, and they are told of the result of the interview within a few days This policy is still proving of value, since applicants are not left in uncertainty about their chances of obtaining a place Applicants who are unable to obtain 1st M B exemption at school spend one year at Queen Mary College, but the number who need to do this steadily decreases For entry to Queen Mary College for 1st M B work, students must satisfy University entrance requirements, but application to go there should be made through the London Hospital Medical College In cases where the applicant from school is able to proceed to either Oxford or Cambridge, the place offered for the whole course becomes automatically transferred for clinical work at a later date The tutorial system in both the preclinical and clinical periods has been extended during the past year and continues to provide a useful method of linking the various parts of the curriculum The departments of physiology and anatomy now regularly run B SC (special) courses in physiology and anatomy, and scholarships are given as a result of the 2nd M B examination to enable suitable candidates to take part in these courses There is no doubt that these senior studies leading to the B SC degree are of great value to students in their future careers Research facilities continue to expand in both the preclinical and clinical field New laboratories for clinical research under the direction of the medical and surgical units have been opened and are proving of great value They have a close association with the professional departments of biochemistry and experimental biochemistry, ensuring that the highest standard of chemical advice will be available to workers in the clinical field Being in the centre of an industrial and residential area, the hospital continues to attract an unrivalled variety of clinical material to its busy outpatient departments Junior research fellowships have been established by the college, the tenure of which is normally one year, so that graduates who have done their house-appointments may gain experience in and have opportunities for original research under supervision. There has been no difficulty in all the newly qualified graduates getting a preregistration appointment, and the majority are able to hold at least their first appointment at the teaching hospital The athletic side of the college has been greatly helped by the opening of a new pavilion at the sports ground at Hale End

ST MARY'S HOSPITAL Medical School has received approval from the University of London for the first stage of the extension of its building and it is expected that this will begin in December, 1958 The extension has become possible as a result of the money raised by the centenary appeal of the school four years ago and also a generous gift by the Wellcome Trustees The university is providing the balance of the cost of the building which will greatly improve the teaching and research facilities of a number of the preclinical and clinical departments when it is completed in three years' time The number of applications for admission to the medical school continues greatly to exceed the number of places and much time is spent by the selection committees in interviewing candidates The Academic Board has decided to reduce the time spent on the introductory clinical course from ten to three weeks, beginning in October, 1958, and a committee is examining the curriculum with a view to other possible changes in the preclinical and clinical courses Princess Margaret honoured the Musical Society by attending a performance of *The Pirates of Penzance* on Dec 11, 1957

For some time the MIDDLESEX HOSPITAL Medical School has been planning the rebuilding of its premedical and preclinical departments A site was obtained very close to the present school and work was started at the end of December, 1957 The building is planned in three phases, the first containing lecture theatres and the large teaching laboratories, together with a special theatre capable of seating 350 and suitable either for lectures or for use by the Students' Dramatic and Musical Societies, &c This section should be completed in time to be used during the first winter term of the session 1959–60 It is hoped then to continue immediately with the second phase, comprising research laboratories, professorial and administrative rooms, dining hall, &c , and accommodation for the Student Health Service, which is run by one of the consultant staff Finally the third phase will be the residential college to accommodate 175 students This block will also include amenities for all students of the school, common-rooms, squash courts, music room, billiards room, games room, &c One of the most cogent reasons for this rebuilding scheme is the need for improved accommodation for students at all stages, and the building committee has given particular thought to the provision of facilities for student activities and to the encouragement of a corporate life within the school, essential in broadening both the general education and the special training of a doctor

The number of applications for admission remains very high, and the school asks prospective candidates to apply two years to eighteen months in advance of the proposed date of entry It is not essential to have any knowledge of chemistry, physics, or biology before entry, for the school teaches these subjects for the 1st M B and admits students to these classes who have satisfied the minimum entrance requirements of the University of London Direct entry to 2nd M B classes may be obtained by those who have gained exemption from the 1st M B through the necessary advanced-level subjects in the General Certificate of Education Students who have carried out their preclinical studies at Oxford or Cambridge are admitted for the clinical course There are excellent clinical facilities, augmented by an arrangement with the Central Middlesex Hospital which allows students to attend there for some instruction as clerks and dressers Certain house appointments are, of course, recognised for preregistration purposes and are reserved for students who qualify from the school. There are also many research appointments in the Bland-Sutton Institute of Pathology, the Courtauld Institute of Biochemistry, the Barnato-Joel Laboratories (Physics), and the Institute of Clinical Research The sports ground at Chislehurst, over twenty acres in extent, provides all the usual facilities and representatives of the various student clubs serve on the athletic-ground committee

During the year 54 students qualified from the ROYAL FREE HOSPITAL School of Medicine, of whom 2 gained honours Extracurricular student activities have included an ambitious but successful production by the Dramatic Society of Arthur Miller's play *The Crucible* This was taken to France in the Easter vacation, under the auspices of the Central Bureau for Educational Visits and Exchanges, and a performance was given for the staff and students of Lille University In athletics the school has provided 4 members of the University women's eight and the same 4 rowed in the British women's eight which competed in the European Championships A third-year student, who is captain of the University Women's Athletic Club and English women's cross-country champion, was second in the women's A A A mile this season The school has been well represented on the Committee of the University of London Students' Union, first by last year's vice-president and this year by the secretary A feature of the year has been the increasing interest shown by senior clinical students in the school's voluntary scheme of training in general practice Some 40 students have attended local practices either continuously for a fortnight, or once weekly for three months, and on present showing it seems that there will be even more attendances next year

ST THOMAS'S HOSPITAL Medical School admits students in October for the course leading to the London M.B , B.S degree They are accepted for premedical or preclinical entry and should apply as soon as they have taken their ordinary levels of the General Certificate of Education and not later than the end of July in the year preceding that of the proposed date of entry Students from the Universities of Oxford and Cambridge are accepted for their clinical training in April and October There are entrance scholarships for both preclinical and clinical students, all of which qualify for Ministry of Education supplementary awards For those London students who do well in the Second Examination for Medical Degrees, scholarships are available to help them to sit for an honours B SC degree in physiology or anatomy Students accepted for preclinical work who are subsequently successful in gaining entry to Oxford or Cambridge are given clinical vacancies There is a wide selection of prizes awarded every year, and after qualification many preregistration and research appointments are available Twice a year there is a very successful course for the final F R C S examination Great stress is paid during clinical training to ward and outpatient work, lectures being kept to a minimum The school has an excellent athletic ground at Cobham, Surrey, some forty-five minutes distant Squash is played in London and the boat club is a flourishing concern, sending a crew every year to Henley The school owns two sailing dinghies, one on the Welsh Harp and one at Burnham The past year has been a very successful one, for the school won the rugger, hockey, fencing, and rowing inter-hospital trophies In support of the Arts there are Choral, Photographic, and Art Societies, while instrumentalists can join the Hospital's Symphony Orchestra which rehearses at the school Every year there is a summer play and a Christmas revue, an event of some importance Films are shown by the Film Society, and the Medical and Physical Society, dating back to 1771, arranges clinical meetings and also invites men and women distinguished in fields outside medicine to lecture during the winter terms

The WEST LONDON HOSPITAL MEDICAL SCHOOL is recognised by the Universities of Oxford and Cambridge for the undergraduate clinical course, and it is hoped that the University of London will shortly restore the recognition which the school previously held In view of the proposed amalgamation of the hospital and school with Charing Cross no more new students will be accepted after October of this year, but there will still be some facilities for students revising for the qualifying examinations

At WESTMINSTER MEDICAL SCHOOL the number of clinical students remains constant at about 200 This is the optimum number, having regard to the clinical facilities available in the Westminster teaching group The applications for admission show a slight decline, but the standard of those accepted is at least as high as in the past The number of students who qualified with medical degrees in 1957 was a record for the school The Westminster teaching group comprises Westminster Hospital (430 beds) in which clinical practice in general medicine, surgery, and obstetrics is undertaken (the orthopædic, ophthalmic, and ear, nose and throat departments are also in the main hospital), the Gordon Hospital (100 surgical beds), The Westminster Children's Hospital (120 beds), and All Saints' Hospital (50 beds) for the practice of gynæcology and urology A close affiliation with St Stephen's Hospital provides very valuable additional clinical practice in medicine Instruction in practical midwifery is also given at St Stephen's Hospital, the Nelson Hospital, and St Teresa's Hospital, and in fevers at the Western Hospital, Fulham Under a voluntary scheme students may reside for a fortnight with general practitioners to see the work of their practice Special instruction in tuberculosis is provided by a fortnight's residence at the King Edward VII Sanatorium, Midhurst, and the teaching of mental diseases is carried out at the Netherne Hospital, London, S W 17 40 vacancies a year in the Westminster Hospital teaching group have been recommended for pre-registration posts, and competition for these is keen A new laboratory has been provided for the chemical pathology department A department of experimental surgery has been organised where already some notable research work has been carried out An additional medical firm will shortly be instituted at the Gordon Hospital The new sports ground at Cobham, Surrey, has been an unqualified success and the improved facilities have been reflected in a higher standard of play and a large number of successes in all outdoor sports

At the SCHOOL OF DENTAL SURGERY of the ROYAL DENTAL HOSPITAL of London, students who have completed the first medical or comparable examination devote one year to the study of general and special anatomy and physiology In the next three years of the course, after preliminary instruction, both theoretical and practical, in dental mechanics, dental materials, and the techniques required for dental conservation work, they attend lectures and clinics on general medicine and surgery at Charing Cross Hospital Medical School and lectures and practice in dental surgery at the dental school Degree students attend for a further period of four or six months before completing their final examination

OTHER ENGLISH SCHOOLS

In the UNIVERSITY OF DURHAM the extensions to the department of anatomy and to the animal house are nearing completion and they should be ready by the end of September As part of the general college plan to provide more residential facilities for students it is hoped to start work in 1959 on a new hall of residence for 225 male students, and conversion and additions to the present buildings should shortly provide accommodation for an additional 80 women students The college has also rented a large hostel from the Ministry of Pensions and National Insurance which, after renovations have been completed, should accommodate an additional 500 male students by next October The hostel will be known as the Eustace Percy Hall, after the late Rector of King's College Once again the Medical Students' Council has been active in representing the interests of medical students both in the college and on the British Medical Students Association Mr Peter G Wood has been elected president of the British Medical Students Association The Medical Athletic Union and the Medical Society have completed their customary full programme of sporting events, visits, lectures, and social activities

At the UNIVERSITY OF BIRMINGHAM* the number of applicants wishing to enter the medical school greatly exceeds the number of places available, and requests for admission should be made by April for first-year courses and by April of the preceding year for second-year courses Applicants within the United Kingdom are interviewed as soon as possible and told the result of the interview within a few days There are 14 places available annually for first-year courses (students from the Colonies or Dominions are generally required to enter upon first-year courses) and about 100 places per annum for men and women for second-year courses in medicine and about 45 per annum in the School of Dentistry It is hoped in the near future, with the building of a new dental hospital, that the annual entry to the School of Dentistry will be increased considerably At present preclinical instruction in dentistry is given in the medical school at Edgbaston and clinical teaching in the Dental Hospital in the city The library service in the medical school is excellent in that not only have students access to one of the largest collections of up-to-date medical literature in the provinces, but the resources of the whole University Library are open to them More especially the medical library has a comprehensive collection of textbooks available on fortnightly loan, and additional copies of textbooks are kept in a reference section for use in the library only A supplementary service is arranged with Messrs H K Lewis, enabling students to borrow standard books at a reduced subscription Since all medical books are housed in one department of the medical school, the student has the advantage of access to all monographs, general medical reference works, and bibliographical tools necessary for clinician and research-worker Ten scholarships are available for selected students to spend an extra year to take the B SC course in either the honour school of anatomical studies or of physiological studies

Students from Oxford, Cambridge, and other universities are encouraged to study clinical subjects at Birmingham. Two interesting scholarships provide the opportunity of spending three months in residence in either East or West Africa principally to gain experience in tropical medicine although part of the time might be spent in some other clinical department. Advanced clinical students may spend some time with selected general practitioners and a prize has recently been instituted for an essay on some topic of general practice. The entire curriculum is under review and an attempt is being made to integrate, as far as possible, the teaching provided by the several departments. The volume of preclinical and clinical research continues to expand. About 300 publications from the faculty of medicine are listed in the current Research Report of the University, and 21 higher degrees were awarded in medicine last year. The Annual Scientific Meeting of the British Medical Association was held in Birmingham in July, under the presidency of Prof. A. P. Thomson, dean of the faculty of medicine. Sport at Birmingham is organised by students through the Guild of Undergraduates, and students may join, without further subscription, any of thirty clubs. The Physical Education Department runs training and coaching schemes which cater for all standards. Sailing and rowing excepted, all sports can be played within 400 yards of the medical school. Future plans include a new physical education department, a sports centre, and a swimming pool.

At the UNIVERSITY OF LIVERPOOL* the outstanding event of the year was the official opening of the new medical school by Queen Elizabeth the Queen Mother on May 7.[1] The new building houses the research laboratories of the departments of medicine, obstetrics and gynæcology, pathology, bacteriology, pharmacology and general therapeutics, and radiodiagnosis, six tutorial classrooms, three lecture theatres, two large class laboratories, the dean's offices, a staff common-room, and a committee room. 91 new students were admitted to the M.B. course in October, 1957, 42 into the first year and 49 into the second year. The number of applications for admission is slightly down on previous years, but a full complement of students will begin their studies in October, 1958. There have been no changes in the requirements for exemption from the 1st M.B., and passes at the advanced level in chemistry, physics, and biology (or botany and zoology) are still required. Discussions are proceeding on the implications of the new recommendations of the G.M.C. on the medical curriculum, but no changes have as yet been made. A full-time readership in medicine has been established, and Dr. C. A. Clarke appointed to the post. Prof. T. N. A. Jeffcoate is visiting Canada, U.S.A., and the West Indies as Sims-Black Commonwealth Travelling Professor in obstetrics and gynæcology. Prof. R. M. Gordon, who has been a professor in the Liverpool School of Tropical Medicine since 1930, retires from the chair of entomology and parasitology at the end of the session after long and distinguished service. Mr. A. McKie Reid retires from the post of lecturer-in-charge of the department of ophthalmology. Dr. Robert Coope, Mr. Hugh Reid, and Mr. John McGibbon retired earlier in the session after long and invaluable service to the university and medical school.

At MANCHESTER UNIVERSITY* the major change during the past session has been the introduction of revised regulations for exemption from the 1st M.B. examination. As from October, 1958, candidates who have passed in chemistry, physics, and biology (or zoology) at the advanced level of the G.C.E. will be entitled to exemption. In future, therefore, the majority of students will enter upon the second year of the course, and be able to complete their qualification in five years. The scheme whereby senior students who wish to do so may spend two weeks with a local general practitioner has been very popular.

At the UNIVERSITY OF LEEDS* the new premises for the department of psychiatry were opened in January, 1958; they are in Hyde Terrace, near the department of biochemistry. Three large houses have been converted for the use of the department and provide administrative, library, research, and teaching accommodation, and also accommodation where patients can be seen. While it remains the long-term plan to provide this accommodation within the teaching hospital, in the meantime these new premises add greatly to the facilities available to the department. The building of the Martin Wing of the teaching hospital is well advanced and it is hoped that the full-time professional units of medicine and surgery will be able to move into their new quarters before the end of next session. No big changes in the curriculum have been made during the past year, nor are any likely in the immediate future, though consideration is being given to entry requirements and the content of the premedical part of the course. There has been only a small reduction in the number of applications for entry, which continue to exceed the number of places available.

In the UNIVERSITY OF SHEFFIELD,* although new university building has not so far greatly affected the medical school, a generous grant from the Rockefeller Trustees has furthered the activities of the department of microbiology. Assistance from the Sheffield Town Trustees has enabled the University to take a larger share in developing the department of psychiatry, and the building by the United Sheffield Hospitals of the new Whiteley Wood Clinic (an extension of the idea of a psychiatric wing within a general hospital) has also greatly assisted the department. The laying, by Queen Elizabeth the Queen Mother, of the foundation stone of a new outpatient department for the United Sheffield Hospitals indicates definite progress towards the ultimate provision of a complete new teaching hospital.

The discussions regarding the curriculum, mentioned in last year's report, are expected to lead next summer to considerable changes in the clinical part of the course. The arrangements for clerkships and dresserships will be modified, there will be changes in examinations and timetable, and two "elective periods" will be introduced. Partly in order to assist the students in the arrangement of their work during these periods, Dr. I. B. Sneddon, lecturer in dermatology, has been nominated as director of clinical studies. A pilot experiment relating to the development of a "tutorial" scheme already shows much promise of success.

Prof. R. P. Jepson has resigned from the chair of surgery on his translation to the University of Adelaide, Prof. William Hobson from the chair of social and industrial medicine to take up a W.H.O. appointment in Copenhagen, and Dr. John Pemberton from the same department on his appointment as professor of social medicine in Queen's University, Belfast. The future of the department of social and industrial medicine in Sheffield is being given careful consideration by the University.

In the UNIVERSITY OF BRISTOL the number of applications for the undergraduate courses in medicine and veterinary science has remained as high as for several years past, and those for the course in dental surgery have further increased. Major alterations are now taking place in the teaching hospital to improve the clinical facilities and accommodation for students. Some modifications in the medical curriculum have been introduced, mainly with the purpose of allowing a greater amount of voluntary attendance in lecture courses. The new medical school is in the planned stage and building is expected to begin in the autumn. Extensions to the dental school are anticipated in the near future, so that more students can be accepted in the clinical years. The teaching staff has been expanded and a new chair in dental medicine has been created The veterinary school has further improved its clinical facilities, the chief addition this year being a new operating-theatre

---

[1] See *Lancet*, 1958, i, 1066.

* The entrance requirements for the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham are laid down in the pamphlet, *University Entrance Requirements 1951–1955*, copies of which may be obtained from the Secretary to the Joint Matriculation Board, 315, Oxford Road, Manchester, 13. Additional faculty requirements may, however, be imposed; details can be obtained from the dean of the faculty of medicine in each university.

WALES

The WELSH NATIONAL SCHOOL OF MEDICINE last year sustained a serious loss in the death of Lord Aberdare, its president for many years The Court of the University of Wales has elected as his successor Sir Clement Price Thomas, who is a past student of the School During the past year, the details of the schedules of accommodation for the new teaching centre in Cardiff have been agreed with the Welsh Board of Health It may be some time before building can start, but there is every hope that the architectural competition can soon be announced for a centre in which educational and hospital accommodation will be completely integrated In the meantime, the school is proceeding with the building of a dining hall and library, which will have the effect of improving amenities for students Additional houses have also been acquired so that hostel accommodation will be adequate for all those who desire it The authorities of the school are at the moment, like many others, engaged in carrying out a revision of the curriculum, but although it is not likely that this will be completed for some time, improvements are being made especially in the direction of correlating teaching in different departments The Student Health Service of the University of Wales, which is administered by the medical school, is extending its activities and it is hoped to provide more and better accommodation One of the postgraduate diplomas which attracts many students from overseas—namely, the tuberculous diseases diploma—will, in future, embrace chest diseases with an alteration in title to diploma in tuberculosis and chest diseases (D T C D) This is the first step in developments which are contemplated in the department of tuberculosis During the past year, a careful review of the preregistration appointments in the Welsh region has been made, and efforts are successfully being completed to ensure that the time spent in these appointments becomes a real extension of medical education The cooperation of the regional consultants with the teachers of the school is assured

SCOTLAND

At the UNIVERSITY OF ABERDEEN the curriculum for the degrees of M B, CH B extends over six academic years Courses in the premedical and preclinical subjects are given in departments located in Marischal College and in Old Aberdeen which provide instruction to science as well as to medical students Laboratory and lecture courses in the three clinical years are conducted in the University buildings on the Foresterhill site where the main hospitals are, and clinical instruction is given in all the hospitals in Aberdeen During the year a building to accommodate a special research department in clinical midwifery was completed and officially opened on April 22 It is staffed by the Medical Research Council and its honorary director is the professor of midwifery Plans have been prepared for a new medical physics building on the Foresterhill site, but it is unlikely that work will be started until early in 1959 During the year a new medical ordinance promoted by the four Scottish universities has been approved It permits certain candidates for admission to the medical faculty to sit the professional examination in physics, chemistry, and biology without attending University classes in these subjects Each university can make regulations for this purpose, but so far the University of Aberdeen has not done so They consider that the time has come to review as a whole the ordinances which govern medical education in the four Scottish universities These were made as long ago as 1911 and are so restrictive in character that they interfere seriously with the prevailing mood of medical educationists in seeking experiment It is proposed that a conference of the Scottish universities should be held early next term to consider the question of preparing new ordinances The number of students for admission continues to fall, but it is still above the number of places available An increasing number of applications are coming from overseas students in various parts of the Commonwealth

At the UNIVERSITY OF EDINBURGH, the past year has been one of continuing activity The number of applicants for admission in October, 1958, to the M B, CH B course remains high in relation to the number of places available Those applying for admission for the course beginning in October, 1959, should submit their applications to the dean of the faculty by Dec 31, 1958 A limited number of undergraduate bursaries and scholarships are available to students in the faculty of medicine for advanced courses of study—e g, an honours course of instruction for the B SC degree The University conducts postgraduate courses leading to the diplomas in medical radiodiagnosis (2 years), medical radiotherapy (2 years), psychiatry (6 months full-time), public health (9 months), and tropical medicine and hygiene (6 months) Graduate scholarships and fellowships are also offered, being open to graduates in the faculty of medicine of any university, to graduates in the faculties of arts or science of any university who hold an honours degree, and to licentiates in medicine The holders of such awards are required to undertake research work in a department within the faculty of medicine The Edinburgh Post-Graduate Board for Medicine (see p 472), which is an advisory council to the University, provides courses of instruction leading to the higher qualifications granted by the Royal Colleges of Edinburgh

At GLASGOW UNIVERSITY the number of applications for admission to the medical school is very similar to that for last year, but it is still in excess of the number of available places The number of applications for entry to the dental school, which had shown a sudden and welcome increase last year, has gone up still further this year The veterinary school has also had more applications

Plans are well advanced for the building which will house the new department of virology and also an extension to the genetics department It is hoped that the new building will be occupied in two years' time The dental school has acquired an extensive site adjacent to the Dental Hospital, which will provide additional accommodation mainly for postgraduate activities In the veterinary school the animal hospital and associated buildings for clinical instruction are now in full operation The farm, which was purchased three years ago, is being developed as a field station, offering facilities for instruction in animal husbandry and preventive medicine It is hoped that a start will be made this year on a new unit for experimental surgery, which will be housed adjacent to the veterinary Hospital The most important staff changes are the promotion of ordinances for the institution of chairs in orthopædics and in infectious diseases The junior teaching staff has been augmented by several additions to the lecturer grade

At the UNIVERSITY OF ST ANDREWS instruction in the subjects of the clinical years of study is given at Dundee, while the premedical and preclinical subjects may be studied either at St Andrews or at Dundee The course of study lasts six years The annual intake of students to the faculty of medicine is limited to between 70 and 80 to ensure that the hospital facilities available are sufficient to allow of adequate clinical instruction being given to each undergraduate The laboratory accommodation in both preclinical and clinical years has been recently extended and provides excellent facilities for students Both at St Andrews and Dundee there are residences which accommodate undergraduates from all faculties Medical students in their early years are encouraged to reside in these to make contact with undergraduates of other faculties

IRELAND

At the UNIVERSITY OF DUBLIN, there has been a considerable increase in applications for places in the medical school, but admission is restricted so that the number in the clinical years will be approximately 50 The clinical tutorial system, instituted two years ago, continues to work satisfactorily The period of residence in a maternity hospital has been increased, and new courses in pædiatrics will be given jointly by the National Children's Hospital and the pædiatric staff at the Rotunda The teaching of pathology in the hospitals has been further extended Reconstruction of laboratories is now approaching completion, and plans are in hand for new accommodation for the department of pharmacology

The SCHOOLS OF SURGERY, DUBLIN, including Carmichael and Ledwich Schools, are attached by charter to the Royal College of Surgeons in Ireland. The college admits to the preregistration classes approximately 100 students each year The normal method of entrance is by competition in the preliminary examination, but a limited number of places is given to those with exceptional qualifications and to certain students selected by the Colonial Office, to which all colonial students should apply, because, owing to limitation of numbers, they cannot be admitted to the entrance examination Nearly all students take the Irish Conjoint Board's examination but some take in addition the London examination. The Schools were inspected by delegates from London University four years ago and as a result were "recognised" for a further period of five years After an inspection in 1957 the Schools were formally recognised by the Commonwealth of Massachusetts Students are medically examined at the start of the preregistration year and again before the start of the clinical years Two doctors give free medical care to students and there are a men's warden and a lady dean of residence to help students in obtaining suitable accommodation and in other ways The playing fields of 16 acres and the pavilions are among the best in Dublin. Recently the laboratory space for chemistry and physics has been doubled, two rooms for advanced work have been added to the anatomy department together with a new lecture-room and much additional apparatus obtained for the pathology, physiology, and physics department. In addition a large room has been constructed for the Men's Union.

The ROYAL COLLEGE OF SURGEONS IN IRELAND is in the unique position of being by charter an undergraduate school of medicine undertaking the full training in the basic sciences and in the preclinical and clinical courses In the college buildings in Stephen's Green in the middle of the city are the laboratories for biology, physics, and chemistry, and for biochemistry, physiology, and pathology, as well as an unusually large anatomy department, five large lecture theatres for formal lectures, examination, administration, and reception rooms, the college library, a restaurant for the students, and the Union common-rooms for men and women. For midwifery and gynæcology any of the three well-known Dublin maternity hospitals are available to college students and for general hospital work any of the ten Dublin clinical hospitals and the usual specialist hospitals are available The Students' Union caters for about twelve other societies—scientific, musical, dramatic, rowing, football, boxing, &c—and most of these compete with visiting universities, Irish or otherwise Students are examined radiologically on entrance, tuberculin-tested, and, if they wish it, given B C G The radiological examination is repeated before commencing clinical work The great majority of students take the examinations of the Irish Conjoint Board and a few take the English Conjoint and the London University examinations

At QUEEN'S UNIVERSITY, BELFAST, the number of entries to the medical school each year is restricted to 108, of which up to 20 places are reserved for the school of dentistry Priority is given to applicants whose parents are normally resident in Northern Ireland, but a number of places are reserved for selected candidates from Great Britain and overseas Details of the entrance requirements may be obtained from the Secretary, Faculty of Medicine, 25, University Square, Belfast, or from the Clerk of Admissions, Queen's University, Belfast The Institute of Clinical Science, which was opened in May, 1954, provides exceptional facilities for the clinical teaching of undergraduates and of research for postgraduates A new department of anæsthetics was opened during this year It is hoped to fill lectureships in therapeutics, mental health, and dental pathology in the coming session

The NATIONAL UNIVERSITY OF IRELAND has colleges in Dublin, Cork, and Galway

The medical school of UNIVERSITY COLLEGE, DUBLIN, has for over sixty years been the largest in Ireland It was founded by Dr John Henry Newman and formally opened as the medical school of the Catholic University in 1855 From 1882 to 1909 it was separated from University College, with which it was fully reunited in 1909 In 1956–57 the school had 500 undergraduates in training for the degrees of M B, B CH, B A O, in the National University of Ireland Annual entry is restricted to 100 During the past year the school's relations with its affiliated hospitals, the Mater Misericordiæ, St. Vincent's, the National Maternity Hospital, and the Coombe Lying-in Hospital, have been put on a new basis There are now professorial units with professors and tutors in medicine and surgery appointed by the college in each of the two general hospitals, and the college also controls all appointments to their junior teaching staffs Similar arrangements exist with the two maternity hospitals New chairs in therapeutics, pharmacology, and medical microbiology have been established in the college The senior professors of medicine and surgery are completely whole-time A number of other Dublin hospitals are associated with the school and attended by small numbers of its students or available for special purposes The school controls appointments to the teaching staffs of two great pædiatric hospitals—Our Lady's Hospital for Sick Children, Crumlin, and St Joseph's Children's Hospital, Temple Street.

For some years past UNIVERSITY COLLEGE, CORK, has restricted its entry to 36 medical and 12 dental students, only 2 of whom may be from overseas Selection is made by the premedical or predental examinations, since it is felt that this gives a better index of the student's capability of profitable study under university conditions than does any other method The school has reverted to the six-term period of study in anatomy, physiology, and biochemistry in preparation for the 2nd M B The introductory clinical course has been abolished Instead, the department of physiology gives instruction in clinical physiology in hospital during the last term, there is an introductory course in pharmacology, and the student receives instruction in elementary pathology, a question bearing on this subject being included in the professional examination in anatomy The results of this approach to the problem of "integration" are being watched Apart from obstetrical and specialist units, there are over 500 acute beds available for clinical study, distributed between three general teaching hospitals The small annual intake was chosen to enable the optimum student/bed and student staff ratio to be achieved Increasing attention is being given to research, since it is realised that teaching, though a primary function of any medical school, is not enough for maintaining its morale Notable contributions have already been made by the departments of biochemistry, physiology, and anatomy The resources of the department of anatomy have lately been augmented by the completion of two research laboratories, the cost of which was generously contributed by the Wellcome Trust, and in this recognition of its industry, the medical school sees a happy augury of future expansion and development.

GALWAY Medical School was established in 1849, as the medical school of the Queen's University in Ireland The Queen's University was replaced by the Royal University of Ireland in 1882, and the Royal University was replaced by the National University of Ireland in 1909 Despite these changes, the work of the medical school was carried on without interruption, and the teaching staff and graduates of each university body were recognised by the succeeding university body

University College, Galway, is one of the three institutions which are federated into the National University of Ireland Galway, like Cork and Dublin, has its own charter, but is subject in matters of major policy to the Senate of the National University of Ireland The medical school is housed partly in the University College buildings and partly in the nearby Galway Regional Hospital—neighbouring buildings forming, in effect, one unit from the school's viewpoint The hospital (recently erected at a cost of over £1½ million) contains general surgical, general medical, obstetrical, fever, pædiatric, eye, and ear, nose, and throat units The members of the senior staff of the hospital are all clinical teachers of the college, the medical school has, under the Health Act of 1953, been allowed to have a 50% representation on the special selection boards of experts who select candidates for appointment to senior hospital posts Thus it can be said that the medical school exercises a measure of control over the appointments to the hospital medical staff, and accordingly of the clinical teaching of the hospital All the professors of the clinical subjects are members of the hospital staff

Degrees and Diplomas

EXAMINING BOARDS

English, Scottish, and Irish Conjoint Boards

THE Examining Board in England by the Royal College of Physicians of London and the Royal College of Surgeons of England examines candidates for the qualifying diplomas of L R C P, M R C S Candidates satisfying the board's regulations in regard to the preliminary examination in general education are eligible for admission to the premedical examination in chemistry, physics, and biology, and are required to complete the professional curriculum subsequently at a recognised medical *school* Copies of the regulations, with a calendar showing the dates of examinations, may be obtained, free of charge, from the secretary to the Examining Board in England, the Examination Hall, Queen Square, London, W C 1

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas—designated by the letters L R C P E, L R C S E, L R F P S—of all three bodies Candidates may work for the examination of the Scottish Conjoint Board at any of the recognised medical schools of Great Britain and Ireland The course lasts six years and includes, in addition to the preliminary examination in the natural sciences—i e, chemistry, physics, and biology—three professional examinations the first in anatomy and embryology, physiology, biochemistry, and biophysics, the second in pathology and bacteriology and pharmacology, and the final in medicine, surgery, midwifery, forensic medicine, and public health Details may be had from the registrar, 18, Nicolson Street, Edinburgh

The Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland examines candidates for the qualifying diplomas of the L R C P I and L M, L R C S I and L M After passing an approved examination in general education, candidates are required to do a one-year course in chemistry, physics, and biology, these subjects being treated with special reference to their applications in medicine After passing the preregistration examination in these subjects a five-term course of anatomy and physiology follows There is then a preclinical term with an introductory course at the hospital and this is followed by three years' clinical work There are three professional examinations Candidates are accepted from most of the recognised schools at home and abroad, but in practice 99% of the candidates are from the Schools of Surgery, which are controlled by the Royal College of Surgeons in Ireland The Irish Conjoint Board thus differs from the English and Scottish Boards in that it has a large teaching school under the control of one of its constituent colleges

Apothecaries' Licences

The Society of Apothecaries of London grants the L M S S A Lond to candidates who pass the primary examination (which is held quarterly) and the final examination Final examinations are held monthly, except in September The minimum period of study is normally five years The four parts of the final examination may be taken together or in any order Regulations and a schedule of the required courses of study may be obtained from the registrar, Apothecaries' Hall, Black Friars Lane, E C 4

The Apothecaries' Hall of Ireland is an examining and licensing body Candidates for examination must be registered *medical students* The diploma, L A H Dublin, confers on holders the right of registration in the Medical Registers of Ireland and Great Britain An examination in practical pharmacy is a compulsory part of the qualifying examination A course of lectures in the subject is given at the hall prior to each session of examinations The latter are held three times yearly—in March, June, and November Further information can be had from the registrar, 95, Merrion Square, Dublin

UNIVERSITY DEGREES

Bachelor of Medicine and Surgery

All the universities in the United Kingdom, except Nottingham, Reading, Southampton, Hull, Leicester, and Exeter, offer baccalaureate degrees in medicine and surgery, conferred on the results of examination

HIGHER QUALIFICATIONS

Those who have graduated in medicine and surgery are at liberty to seek higher qualifications if they wish

Doctor of Medicine and Master of Surgery

Graduates holding bachelor's degrees can take the degree of doctor of medicine or master of surgery All universities with medical faculties in Great Britain and Ireland confer such degrees Liverpool offers the orthopædic degree of M CH ORTH

Master of Midwifery

The Society of Apothecaries of London grants the *mastery* of midwifery (M M S A) upon examination in obstetrics, pædiatrics, and public health The examinations are held in May and November, and regulations may be obtained *from the* registrar, Apothecaries' Hall, Black Friars Lane, E C 4

MEMBERSHIP AND FELLOWSHIP

The Royal College of Physicians of London confers the membership (M R C P), which is obtained by examination Examinations are held four times in each year, and medical graduates and licentiates of the college over twenty-three years of age may sit for it Details can be obtained from the Secretary, Royal College of Physicians, Pall Mall East, London, S W 1 Fellows of the college are elected annually at a general meeting *of the college*

The Royal College of Surgeons of England grants a *fellowship* to those passing the primary and final F R C S examinations The primary examination is open to those who hold a qualification registrable in the British Medical Register and to graduates in medicine and surgery of universities and medical colleges recognised by the council Subjects of the primary examination are anatomy (including normal histology), applied physiology, and the principles of pathology The final examination can be taken in general surgery, ophthalmology, or otolaryngology To be admitted to the final examination in general surgery candidates must produce evidence of having been engaged in acquiring professional knowledge for not less than three years after taking a recognised medical qualification, and of having held the requisite resident surgical posts during a part of that time. Candidates for the final examination in ophthalmology or otolaryngology must have been qualified for three years and must have held general and specialist resident posts during an aggregate period of eighteen months. The primary examination is held in February, June, and October, and the final examination is held in May and November. The college also grants a fellowship in dental surgery. The primary examination is open to those with a dental qualification registrable in the British Dentists Register, and to graduates and diplomates in dental surgery of universities and licensing bodies recognised by the council. Subjects of the primary examination are applied anatomy, and applied physiology, and the principles of pathology, with special reference to the teeth and jaws, and of the final examination surgery, oral pathology, and bacteriology in dental surgery. The Faculty of Anaesthetists has been formed within the college, and the College grants a fellowship in the Faculty by examination. Subjects for the primary examination are anatomy, physiology, pathology, and pharmacology, and for the final, anæsthesia and analgesia, medicine and surgery, and the application of the basic sciences to anæsthetics. Copies of the regulations and full particulars may be obtained from the Examinations Secretary, Examination Hall, Queen Square, London, W.C.1.

Medical graduates who desire to specialise in obstetrics and gynæcology may apply for entry to the Membership examination of the Royal College of Obstetricians and Gynæcologists (M.R.C.O.G.). A minimum of three years' residence in hospital posts recognised for the examination is required before application is made. The Fellowship (F.R.C.O.G.) is granted to members who are judged by the council to have advanced the science and art of obstetrics and gynæcology.

Graduates may become members of the Royal College of Physicians of Edinburgh (M.R.C.P.E.) on passing an examination, particulars of which may be obtained from the secretary, 9, Queen Street, Edinburgh, 2. The fellows are selected from among members by the council of the college, and receive the designation F.R.C.P.E.

Fellowship of the Royal College of Surgeons of Edinburgh (F.R.C.S.E.) is granted to medical graduates who pass the required examinations. The examination is divided into two parts—the first on anatomy, physiology, pathology, and bacteriology, and the second on the principles and practice of surgery and on one of four special subjects to be chosen by the candidate. Particulars of the regulations may be obtained from the clerk of the college, Surgeons' Hall, 18, Nicolson Street, Edinburgh.

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a fellowship *qua* physician and a fellowship *qua* surgeon registrable by the G.M.C. as an additional qualification (F.R.F.P.S.). Admission is by examination and subsequent election. Candidates for the fellowship in medicine must have been in possession of a recognised medical qualification for not less than two years, and must have been engaged during one of these years in full-time clinical work in a recognised hospital and have spent one other postgraduate year in approved medical work. The examination comprises a clinical examination in medicine, written and oral examinations in the principles of medicine and medical pathology, and written and oral examinations in the practice of medicine and therapeutics. Candidates for admission to the fellowship in surgery are required to possess a recognised medical qualification and to pass a primary and a final examination. The primary examination consists of written and oral examinations in anatomy and in physiology, pathology, and bacteriology. Candidates who have passed the primary fellowship examination of the Royal College of Surgeons of Edinburgh, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, or the Royal Australasian College of Surgeons will be exempted from the primary examination for the fellowship of the faculty *qua* surgeon. For admission to the final examination candidates must have been in possession of a recognised medical qualification for not less than two years and produce evidence that they have been engaged, after qualifying, for one year in full-time clinical work in a hospital approved by the council and for a further year in the study of surgery. The final examination comprises a clinical examination in surgery, written and oral examinations in surgical anatomy and surgical pathology, and written and oral examinations in surgery. Alternatively, candidates may submit themselves for examination in one of the following subjects: obstetrics and gynæcology, ophthalmology, or otorhinolaryngology. Details may be had from the Registrar of the Royal Faculty of Physicians and Surgeons, 242, St. Vincent Street, Glasgow, C.2.

Membership of the Royal College of Physicians of Ireland (M.R.C.P.I.) is granted on the result of an examination, the details of which may be obtained from the registrar of the college, 6, Kildare Street, Dublin. Fellows are elected by ballot from among the members, and receive the designation F.R.C.P.I.

Graduates seeking the fellowship of the Royal College of Surgeons in Ireland (F.R.C.S.I.) must pass in two examinations, a primary in anatomy, physiology, and the principles of pathology, and a final in surgery, including some pathology. There are three examinations each year. Exemption from the primary is given to candidates who have passed this examination since 1951 at the Royal Colleges of London, Edinburgh, or Australasia, or at the Royal Faculty of Glasgow. A full-time four-month course in preparation for the primary examination begins on Oct. 1 and March 1 each year: the number of places is limited. Further particulars may be obtained from the registrar, the Royal College of Surgeons in Ireland, Dublin.

The Faculty of Radiologists offers a Fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at approved hospitals, hold a radiological diploma, and have practised radiology exclusively for at least two years after obtaining that diploma. Candidates are required to pass an examination in radiodiagnosis or radiotherapy, and in general medicine, general surgery, and pathology. Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, or pathology. Full particulars may be obtained from the Warden, the Faculty of Radiologists, 45, Lincoln's Inn Fields, London, W.C.2.

SPECIAL DEGREES AND DIPLOMAS

The regulations for the following diplomas can be obtained by applying to the examining bodies concerned.

Anæsthetics

The English and Irish Conjoint Boards offer diplomas in anæsthetics (D.A.). The Faculty of Anaesthetists grants a fellowship (F.F.A.) on examination.

Bacteriology

Diplomas in bacteriology are granted by the Universities of London and Manchester and in bacteriology and microbiology by the University of Bristol.

Child Health

Diplomas in child health (D.C.H.) are granted by the National University of Ireland and the English and Irish Conjoint Boards.

Clinical Pathology

The University of London offers a diploma in clinical pathology (D.C.P.).

Industrial Medicine

The Royal Faculty of Physicians and Surgeons of Glasgow, the Society of Apothecaries of London, and the English Conjoint Board offer diplomas in industrial health (D.I.H.)

Laryngology and Otology

The English Conjoint Board offers a diploma (D L O) for those who have made a special study of the ear, nose, pharynx, and larynx The final examination for the F R C S and for the F.R F P S may be taken in otolaryngology

Microbiology

The University of Sheffield awards a diploma in this subject after a *full-time* course of study extending over one university session Entrants will normally be expected to be graduates of a university, but the senate may deem other qualifications as equivalent for this purpose

Obstetrics and Gynæcology

The Royal College of Obstetricians and Gynæcologists grants by examination a diploma (D OBST) to graduates with postgraduate hospital experience in general medicine or surgery and in obstetrics The University of Dublin also offers a diploma (D G O) The higher qualification granted by the Society of Apothecaries of London has already been mentioned The final examination for the F R F P S may be taken in obstetrics and gynæcology

Ophthalmology

The English and Irish Conjoint Boards issue a diploma in ophthalmology (D O and D O M S respectively) The final examination for the F R C S and for the F R F P S may be taken in ophthalmology

Orthopædics

The University of Liverpool offers the degree of M CH ORTH which is open to medical graduates of an approved university who hold the fellowship in surgery of one of the British colleges or of the American College of Surgeons

Parasitology and Entomology

The University of London awards a certificate and a diploma in applied parasitology and entomology

Pathology

The English Conjoint Board offers a diploma in pathology (D PATH)

Physical Medicine

The English Conjoint Board offers a diploma in physical medicine (D PHYS MED)

Psychological Medicine

The Universities of London, Dublin, Durham, Edinburgh, Ireland (National University), Leeds, and Manchester, and the English and Irish Conjoint Boards offer diplomas in psychological medicine

Public Health

A diploma in public health (D P H) is granted by the English Conjoint Board and by all the universities of Great Britain, except Cambridge, Oxford, Birmingham, Reading, Sheffield, Nottingham, Southampton, Hull and Exeter, and also by the National University of Ireland

Radiology

The Faculty of Radiology grants a fellowship (F F R) The University of Edinburgh and the English Conjoint Board offer two diplomas—one in medical radiodiagnosis (D.M R D) and one in medical radiotherapy (D M R.T) The University of Liverpool offers a diploma D M R (D) or (T) obtainable by examination after a two-year course in diagnosis or therapy, after a further two years diplomates may be awarded the M RAD by presentation of a thesis

Tropical Medicine

A diploma in tropical medicine and hygiene (D T M & H) is granted by the University of Edinburgh, by the University of Liverpool jointly with the Liverpool School of Tropical Medicine, and by the English Conjoint Board The University of London has an academic postgraduate certificate and an academic postgraduate diploma in tropical medicine and hygiene

Tuberculosis and Chest Diseases

A diploma in tuberculosis and chest diseases (D T C.D) is granted by the University of Wales

DENTAL DEGREES AND DIPLOMAS

There are schools of dentistry at the Universities of London, Belfast, Birmingham, Bristol, Dublin, Durham, Edinburgh, Glasgow, Leeds, Liverpool, Manchester, Sheffield, and St Andrews (at Queen's College, Dundee), and at the University Colleges of Dublin *and Cork* in the National University of Ireland London University offers a B D S and an M D S, it also prepares students for the L.D.S of the Royal College of Surgeons of England This college has a fellowship in dental surgery (F D S) and a diploma in orthodontics (DIP ORTH) A fellowship is also granted by the Royal College of Surgeons of Edinburgh Edinburgh University offers a B.D S and an M D S, Leeds *grants* an L D S, a *baccalaureate degree* (B CH D), and mastership (M CH D), and Manchester *grants* an L D S, a B.D S, an M D S, and also a doctorate in dental science (D D S) Glasgow University and the University *Colleges of Dublin and Cork* grant a B.D S and an M.D S; and Trinity College, Dublin, offers a B DENT.SC. and an M DENT SC St Andrews no longer offers a diploma, but in its place a baccalaureate (B D S), and it has also instituted a doctorate of dental science (D D SC) It continues to offer a diploma in public dentistry (D P D) and an M D S All the other universities mentioned offer L D S, B D S, and M D S Licences in dentistry are granted by the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons in Ireland The Royal Faculty of Physicians and Surgeons confers a higher diploma in dental surgery (H D D) and a diploma in dental orthopædics (D D O)

Postgraduate Education

EACH university in the United Kingdom with a medical school is responsible for the postgraduate education of the region in which it is situated Each has a postgraduate education committee with a dean or director of postgraduate studies as its executive officer

IN LONDON

The British Postgraduate Medical Federation (University of London) provides postgraduate education in the medical and dental specialties, supplementing the opportunities available at the undergraduate schools and teaching hospitals and those provided by the three Royal Colleges The services of the staff of the central office of the Federation are available to all postgraduates, including those from the Commonwealth, the Colonial territories, and foreign countries, in advising on programmes of study and in making the arrangements necessary Each of the three Royal Colleges arranges lectures in various aspects of its specialty, and advises graduates on the suitability of hospital appointments and programmes of study for its higher qualification

British Postgraduate Medical Federation

The British Postgraduate Medical Federation, which is a school of the University of London, comprises the Postgraduate Medical School of London at Hammersmith Hospital (with its university departments of general medicine, general surgery, and pathology) and 14 Institutes, each associated with a special postgraduate teaching hospital or Royal College The numbers of students that can be admitted to the clinical practice of the hospitals with which the Institutes are associated are limited, resident clinical appointments are available to suitable students of the Institutes, and provide the most valuable form of postgraduate education There are opportunities for research by selected graduates At all the Institutes instruction is given throughout the academic year, it is suitable for graduates in the early stages of their specialist education and also for those who have completed their practical training Two or more years of hospital work in general medicine and general surgery after graduation are normally advisable before commencing work in the special branches The work at the Institutes is of an advanced type and is sufficiently comprehensive to enable graduates with suitable practical experience to prepare for higher degrees and diplomas Emphasis is placed on clinical and laboratory teaching, supplemented by lectures and demonstrations Each Institute has a reference library, and takes the current journals relevant to its specialty Most Institutes arrange short symposia, varying from one or two days to a week for Consultants, and there are one-day clinical conferences open to Senior Registrars, chiefly those in general medicine and surgery, throughout the country The programme arranged for the year 1958–59 will be found in the advertisement columns of this issue Short courses and other forms of continuing education for general medical and dental practitioners and local-authority medical officers are arranged at hospitals throughout the four Metropolitan regions, with the assistance of the Regional Advisers in postgraduate medical and dental education The Federation has arranged a ninth series of advanced lectures, entitled The Scientific Basis of Medicine, to be delivered two afternoons a week, at 5 30 P M , at the London School of Hygiene and Tropical Medicine, during the autumn and winter terms of the 1958–59 session The lectures are designed especially for research-workers and specialists in training and are open to all registered medical practitioners without fee Further details are given in the advertisement columns of this issue Three lectures on the Scientific Basis of Dentistry will be given early in 1959

It is essential for prospective postgraduate students from abroad to make their arrangements well in advance, and those who desire the assistance of the central office of the Federation are advised to get in touch with the Director of the Federation, Prof Sir Francis Fraser, M D , F R C P , at the central office, 18, Guilford Street, London, W C 1, as far in advance of their arrival in this country as possible Those sponsored by their universities, governments, or other official bodies receive first consideration in the allotment of vacancies Established specialists from overseas, here for a short time, who wish to see something of the practice of this country, are always welcome, they are regarded as visiting colleagues, and the experts in their specialties are always ready to receive them and let them accompany them in their work and teaching An information bureau of postgraduate activities in London and other university centres is maintained at the central office

The Federation awards annually a number of travelling fellowships, for the purpose of studying abroad, to graduates working in medical or dental schools or teaching hospitals of the University of London

The **Postgraduate Medical School of London** is associated with the Hammersmith Hospital It has university departments in medicine, surgery, and pathology The teaching in the clinical departments is based on ward work which is supplemented by lectures during three ten-week terms starting in January, April, and October A course for the university diploma in clinical pathology, lasting one year, is available for a limited number of selected students The department of radiology of the hospital provides courses for the diplomas in medical radiology of the Conjoint Board A year's course in anaesthesia, consisting of lectures and clinical training, is also provided All these courses begin in October Facilities for research are available for selected students

Address Ducane Road, London, W 12

The **Institute of Basic Medical Sciences** comprises the departments of anatomy, physiology, and pathology of the Royal College of Surgeons of England The Institute cooperates with other specialist institutes of the Federation in providing facilities for practical work and instruction in the basic medical sciences There are opportunities for research for selected graduates Full-time and part-time courses of 14 weeks' duration suitable for candidates for higher degrees and diplomas, begin in January and September A two-month revision course for primary F D S candidates is held twice a year beginning in December and June

Address Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2

The **Institute of Cancer Research Royal Cancer Hospital** comprises the Chester Beatty Research Institute and parts of the departments of physics and radiotherapy at the Royal Marsden Hospital The Institute is concerned with all aspects of research into the causation and treatment of cancer, with the training of research-workers in this field, and with advanced teaching in biophysics, radiotherapy, and problems of atomic energy There are laboratories for chemical, biochemical, and histological investigations into cancer and allied diseases Facilities are afforded to those wishing to pursue research in the clinical and pathological aspects of cancer or the physical and biological foundations of medical radiology, and who may be working for higher degrees, such as the PH D The department of radiotherapy gives a lecture and demonstration course of one week's duration in May and November annually primarily for doctors from overseas, and accepts candidates to train for the diploma in medical radiotherapy A course of lectures for students studying for the M SC degree in biophysics commences in October

Address Fulham Road, London, S W 3

The **Institute of Cardiology** is associated with the National Heart Hospital Six appointments in senior-registrar and registrar grades are available in the hospital and the Institute to provide specialised training for postgraduates who have already had a sound grounding in general medicine Full-time and part-time courses of instruction of about eleven weeks' duration are held twice annually, starting in April and October, and two or three short intensive courses of lectures and demonstrations are held each year in February, June, and November, one of these is for general practitioners

Address 35, Wimpole Street, London, W 1

The **Institute of Child Health** is associated with The Hospital for Sick Children and the Postgraduate Medical School at Hammersmith Hospital, the Queen Elizabeth Hospital for Children, Hackney, also participates in the clinical teaching of the Institute The Province of Natal Model Welfare Centre offers facilities for the study and care of the healthy child The Institute provides tuition throughout the year in three terms of three months each, and in addition a series of lectures by specialists in various spheres is given each term Clinical clerkships are available for selected students

Address The Hospital for Sick Children, Great Ormond Street, London, W C 1

The **Institute of Dental Surgery** is associated with the Eastman Dental Hospital The object of the Institute is to provide postgraduate training in the special branches of preventive and therapeutic dentistry by means of clinical experience, lectures, demonstrations, and research Courses of various lengths are held from time to time in children's dentistry, orthodontics, conservative dentistry, periodontology, prosthetic dentistry, oral surgery, and oral pathology For candidates preparing for the F D S of the Royal College of Surgeons, courses lasting eight months are held twice yearly commencing in October and April For selected students junior staff appointments are available for this period In April and October there are revision courses, lasting eight weeks, suitable for candidates for the final F D S examination A course in orthodontics, of a year's duration, commences in October

Address Eastman Dental Hospital, Gray's Inn Road, London, W C 1

The **Institute of Dermatology** is associated with St John's Hospital for Diseases of the Skin Throughout the year clinical teaching takes place daily in the outpatient department and twice weekly at the inpatient department at Homerton Tutorials in clinical dermatology and histopathology of the skin are given twice weekly during term time In each of the university terms there is a series of lectures and weekly clinical demonstrations Special short courses in histopathology and in medical mycology are also held There are facilities for study and tuition in pathology, including mycology, radiotherapy, and physiotherapy Advanced students may also be eligible for clinical and research assistantships, the former of which are competitive A discussion of cases of special interest, to which students attending the courses are invited, takes place once a week

Address St John's Hospital for Diseases of the Skin, Lisle Street, Leicester Square, London, W C 2

The Institute of Diseases of the Chest is associated with the Hospitals for Diseases of the Chest (the Brompton and London Chest Hospitals) On the medical side, a comprehensive full-time course is conducted for a limited number of graduates who are specialising in chest diseases, during the two terms beginning in October and January, and a more selective one during the summer term A larger number can be accepted for part-time study, which is suitable for those reading for higher medical diplomas Clinical instruction in thoracic surgery, including cardiac surgery, is given throughout the year, and there are courses in the October and January terms *Part-time instruction in radiology of the chest is given for* trainee radiologists Clinical demonstrations and lectures open to the medical profession are given each week

Address Brompton Hospital, London, S W 3

The Institute of Laryngology and Otology is associated with the Royal National Throat, Nose and Ear Hospital There is daily clinical teaching throughout the year The whole-time courses held twice yearly include basic sciences, three months, intensive lecture course, six weeks, practical revision course, two weeks, advanced revision course, two weeks Short courses on special aspects (such as endoscopy, audiology, pathology, aural surgery, and malignant conditions) *are given from time to time*

Address 330/332, Gray's Inn Road, London, W C 1

The Institute of Neurology is associated with the National Hospital and the Maida Vale Hospital for Nervous Diseases, which jointly form a teaching hospital The teaching is mainly by attendance on the hospital practice, supplemented by lectures and demonstrations Two courses in clinical neurology are held annually commencing in January and October Clinical instruction in neurosurgery is given throughout the year *Courses of clinical demonstrations (two weekly)* are held several times a year A course in the technique and clinical application of electroencephalography is held jointly with the Institute of Psychiatry twice a year Advanced students are appointed as clinical clerks in the wards or attached to the special departments and research laboratories

Address National Hospital for Nervous Diseases, Queen Square, London, W C 1

The Institute of Obstetrics and Gynæcology is associated with Queen Charlotte's Maternity Hospital, the Chelsea Hospital for Women, and the Department of Obstetrics and Gynæcology at Hammersmith Hospital The teaching is based on ward work and is supplemented by lectures and demonstrations during two terms of thirteen weeks' duration, which commence in March and September Short intensive courses of a fortnight's duration, held in June and December each year, are suitable for students preparing for the higher qualifications A week's course for general practitioners is held twice a year

Address Chelsea Hospital for Women, Dovehouse Street, London, S W 3

The Institute of Ophthalmology is associated with the Moorfields Eye Hospital In addition to teaching by means of attendance on the hospital practice, a routine lecture and tutorial course, normally covering two terms of approximately sixteen weeks each, is held twice a year commencing in March and October, the first part of the course is devoted to anatomy, embryology, histology, physiology, optics and elementary clinical instruction, and the second part comprises bacteriology, pathology, operative surgery, medical ophthalmology, and all aspects of ophthalmic disease Introductory courses, lasting one week, in orthoptics and contact-lens practice are held during each term Clinical teaching and lectures are given at a higher level for advanced students There are facilities for research for suitably qualified candidates

Address Judd Street, London, W C 1

The Institute of Orthopædics is associated with th Royal National Orthopædic Hospital Training in orthopædic to selected graduates who have already been trained in genera surgery and the basic sciences is afforded by means of clinica appointments, with opportunities for research For graduate requiring a less extensive period of education in the specialty and especially for those who have acquired practical experienc overseas or elsewhere, advanced courses are held at variou times during the year These are of seven to ten days' duratio Twice a year, in the spring and the autumn, a short revisio course of a week's duration in advanced clinical orthopædic is held Both the central hospital in Great Portland Street an the country hospital at Stanmore are attended by postgradua students

Address Royal National Orthopædic Hospital, 234, Great Portlan Street, London, W 1

The Institute of Psychiatry is associated with th *Bethlem Royal Hospital and the Maudsley Hospital* Trainin normally covers three years, after experience elsewhere i general medicine, and is based on responsible hospital dutie under supervision Regular series of lectures and demonstra tions are given throughout each of the university terms, clinical training continues throughout the year and include seminars and case-discussions Students who, because o previous experience, do not wish to take the comprehensiv course are able to attend limited series of lectures and clinical instruction For those who wish to specialise in child psychi atry a six-month course is held twice yearly A course in th technique and clinical application of electroencephalography is held jointly with the Institute of Neurology twice a year A year's course in abnormal psychology for the university postgraduate diploma in psychology is available to holders o an honours degree in psychology There are facilities for original investigations under supervision in the clinical departments and in the psychological, neuropathological, neuroendocrinological, electrophysiological, and biochemical departments

Address Maudsley Hospital, Denmark Hill, London, S E 5

The Institute of Urology is associated with St Peter's, *St Paul's, and St Philip's Hospitals* Comprehensive instruction is given in the wards, outpatient departments, operating theatres, laboratories, &c , throughout the year Weekend courses of demonstrations and lectures are held from time to time for higher examination candidates In addition lectures on venereology are arranged occasionally in cooperation with the Medical Society for the Study of Venereal Diseases, and arrangements can be made for graduates to attend a venereal diseases clinic In the winter months a series of lecture-discussions on urological subjects of interest to the whole profession are held on Wednesdays at 5 P M Limited numbers of clinical assistants are appointed to individual surgeons for personal tuition, and there are also research assistantships

Address 10, Henrietta Street, London, W C 2

ROYAL COLLEGES, HOSPITALS, SCHOOLS, &c

The Royal College of Surgeons of England has arranged a number of lectures and demonstrations to be held at the college A full-time clinical surgery course will be held in September and October, 1958, and in February and March, 1959 This will be limited to two groups of students, 15 in each In addition two series of 24 surgery lectures will be given during October and April and at the same time clinical conferences will be arranged at selected hospitals In anæsthesia three series, each of 36 lectures, demonstrations, and discussion groups, will be given in the autumn, spring, and summer Lectures and clinical demonstrations in oral, dental, and general surgery will be held in conjunction with the

Institute of Dental Surgery in May and October. Lectures and courses are arranged during the year jointly with the Institutes of Laryngology and Otology, Urology, and Ophthalmology. Specialists are available for consultation on postgraduate training in general surgery, dental surgery, plastic surgery, and anæsthetics. Facilities are now available for advice on postgraduate orthopædic training through the postgraduate orthopædic committee which has its headquarters at the college. Residential accommodation is available in the Nuffield College of Surgical Sciences. The Institute of Basic Medical Sciences, formed jointly by the college and the British Postgraduate Medical Federation, has arranged a programme of postgraduate teaching in the basic medical sciences (see above). Information on all these courses may be had from Mr. W. F. Davis, Deputy Secretary, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2.

The ROYAL COLLEGE OF SURGEONS IN IRELAND gives a four-month course in anatomy in preparation for the primary fellowship examinations. There are two courses in each year, one starting in October for the February examination and the other in March for the July examination, but students may join the course at any time. This is a fully comprehensive course. In addition there is a similar course starting at the same time in physiology and the principles of pathology. Details may be had from the registrar of the college.

At ST. MARK'S HOSPITAL, City-road, London, E.C.1, surgeons wishing to specialise in proctology may attend courses of one to six months, and postgraduate students working for higher degrees may come for one to four weeks' whole-time study.

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE offers a number of courses. The following last for one academic year of nine months. The course for the University of London's academic postgraduate diploma in *public health*, commencing each year at about the beginning of October, is designed primarily for qualified medical practitioners who intend to engage in any branch of preventive medicine. There are now no vacancies on the course beginning Sept. 30, 1958. Students may elect to make a special study of one of the following: (1) child health, (2) medical statistics and epidemiology, (3) mental health, (4) occupational health, (5) tropical hygiene, (6) nutrition. Occupational health as a special subject, plus practical work and attendance at clinics (arranged by the school), is recognised by the Conjoint Board and the Society of Apothecaries as fulfilling in part the requirements for entry to examination for the diploma in *industrial health*. The course for the University of London's academic postgraduate diploma in *bacteriology*, commencing about the beginning of October each year, is intended to give advanced instruction to graduates in medicine, science (including veterinary science), or pharmacy who intend to follow a career in bacteriology. There are now no vacancies on the 1958–59 course. Applications for the subsequent session must be received not later than March 1, 1959. The number of places is strictly limited. The course of study for the University of London's academic postgraduate certificate and diploma in *tropical medicine and hygiene*, commencing about the beginning of October each year, is designed to give advanced training in tropical medicine. The preliminary C.T.M. & H. course occupies approximately the first 4½ months of the complete course. The final course consists of advanced study in one of two fields—clinical tropical medicine or tropical hygiene. The course for the University of London's academic postgraduate certificate and diploma in *applied parasitology and entomology*, commencing about the beginning of October each year, is open to candidates with acceptable qualifications in medicine, veterinary medicine, veterinary science, and science. The preliminary C.A.P. & E. course occupies approximately the first 4½ months of the complete course, which is planned mainly for people wishing to take up research or laboratory appointments abroad. There are now no vacancies on the 1958–59 course. Applications for the subsequent session must be received not later than April 1, 1959. The number of places is strictly limited. The five-month course for the Conjoint Board's diploma in *tropical medicine and hygiene* is held twice a year. The next courses begin on Oct. 6, 1958, and Feb. 23, 1959. A course in *statistical methods* applied to medicine and epidemiology is held annually on two days a week from about the beginning of January to about the end of April. Students without a medical qualification can be accepted. A ten-week course in *environmental control* is held twice a year, commencing next on Sept. 30, 1958, and Feb. 23, 1959. Although intended primarily for health inspectors from abroad, the course is so planned as to be of value to medical officers and others interested in the health aspects of environmental control both at home and abroad.

The ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE conducts courses of instruction (starting annually in March and September) covering the syllabuses for the examinations of the Conjoint Board for the diplomas in public health and in industrial health. The next courses will start on Sept. 12, 1958. Students are prepared too for the diploma in industrial health of the Society of Apothecaries. All tuition may be whole-time or part-time. Part-time courses may be commenced at any time. Lectures are given by the internal teaching staff of the institute and by external lecturers. For the diploma in public health, attendance at the health department of a local authority and fever hospital is arranged, and there are visits to places of importance to the public health. For the industrial-health course, practical sessions are arranged at appropriate clinics and departments of hospitals, and arrangements are made with various medical officers and others in representative industries for visits to works under their supervision. Full information, entry forms, and prospectuses may be obtained from the Dean, 23, Queen Square, London, W.C.1, or from the Secretary, 28, Portland Place, London, W.1.

The Institute is a medical corporation, incorporated by Royal Charter. Under its present name, the Institute came into being in October, 1937, as a result of the amalgamation of the Institute of Hygiene and the Royal Institute of Public Health, upon the granting of a supplemental Royal Charter to the Institute of Hygiene. Among its main objects and work are:

Laboratory work.—The bacteriological, chemical, and serological laboratories are available for the examination and investigation of pathological specimens, water, milk, sewage, &c.

The Museum of Hygiene.—The Institute maintains a permanent educational health exhibition, open free to the public daily from 9.30 A.M. to 5 P.M. at 28, Portland Place, W.1.

Lectures by medical and scientific authorities upon topics relating to public health and hygiene are given at spring and autumn sessions. The Harben and the Bengué Memorial Award lectures are delivered annually at the Institute, and the Blackham lecture triennially.

Examinations for the certificate and the diploma of the Institute are held twice yearly (in January and June) in London and at centres throughout the British Isles in the following separate subjects: general hygiene, school hygiene, and mothercraft and child welfare.

The TAVISTOCK CLINIC is an outpatient centre devoted to psychotherapy both of adults and of children on broadly psycho-analytic lines, and to providing training in certain skills in this field. Special attention is at present being given to the development of techniques in handling parents of disturbed children, to marital problems, and to group therapy of adults. In addition, the clinic and the associated Tavistock Institute of Human Relations are engaged in research in the fields of child development, personality, preventive psychiatry, and applied social science. A number of registrar and senior registrar posts are established in the adult and the children's and parents' departments. The following courses of training are available:

(1) Full-time training in psychotherapy, with special reference to the needs of the National Health Service, carried out in conjunction with the tenure of registrar and senior-registrar appointments in the adult department. Personal analysis is available as part of this training.

(2) A two-year full-time course in child psychiatry (for registrars)

(3) A two-year part-time introductory course in psychotherapy, including group experience (open to selected trainee psychiatrists from other N H S institutions)

(4) Introductory courses for general practitioners dealing with the patient-doctor relationship and with psychological factors in ill health

(5) A more advanced two-year course in psychotherapy in general practice for limited numbers of family doctors

(6) Several courses in the Rorschach method of personality assessment (by arrangement with the Institute of Human Relations), open to doctors with relevant experience

In addition there are training courses in clinical psychology, educational psychology, advanced social casework, and child psychotherapy, open to graduate psychologists (non-medical) and social workers, in some instances during their tenure of trainee posts or fellowships Both sides of the clinic also conduct regular case-conferences and other types of instruction with their internal students which may be open to limited numbers of suitably qualified professional workers from home or overseas on request and by permission From time to time lectures are advertised open to limited numbers of psychiatrists and workers in related fields Further information may be had from the Medical Director, 2, Beaumont Street, London, W 1

The TAVISTOCK INSTITUTE OF HUMAN RELATIONS is concerned with applied social research and the provision of advisory services in problems which may cover the family, the factory, the hospital, or the community Further information may be obtained from the Secretary, Tavistock Institute of Human Relations, 2, Beaumont Street, London, W 1

The INSTITUTE OF PSYCHO-ANALYSIS, 63, New Cavendish Street, London, W 1, provides training in psycho-analytic theory and technique The course is part-time and lasts about four years It includes a personal analysis, attendance at lectures and seminars (held in the evenings), and clinical work done under supervision Students are required to obtain general psychiatric experience at other clinics and hospitals since the Institute does not set out to teach psychiatry Completion of the course to the satisfaction of the training committee qualifies the student for independent work as a psycho-analyst On the recommendation of the training committee, the student is elected an associate member of the British Psycho-Analytical Society and the Institute of Psycho-Analysis Training in child analysis is available for senior students

The FELLOWSHIP OF POSTGRADUATE MEDICINE was founded in 1918 The Fellowship, whose offices are at 60, Portland Place, London, W 1, provides a bureau of general information on postgraduate work, and also arranges various courses of instruction to suit the special needs of postgraduates whose requirements are not met by other existing programmes The Fellowship's arrangements include

(1) Weekend courses, occupying the whole of a Saturday and Sunday These are given in various hospitals in such subjects as infectious diseases, general medicine, the rheumatic diseases, orthopædics, plastic surgery, and clinical surgery

(2) Courses specially suitable for, though not restricted to, candidates for the D C H, D OBST, M R C P, and F R C S (final) These include general medicine, general surgery, midwifery, and children's diseases Some are full-time courses, lasting one or two weeks, others are spread over longer periods, taking place in the mornings, afternoons, or late afternoons, they are intended particularly for postgraduates not free for full-time study

The *Postgraduate Medical Journal*, the official organ of the Fellowship, is published monthly and contains a special section devoted to general postgraduate news and information about the work carried on in all the main centres of teaching throughout the British Isles The Journal can be obtained by subscription or in single copies

The TUBERCULOSIS EDUCATIONAL INSTITUTE is a body composed of representatives from the Joint Tuberculosis Council and the National Association for the Prevention of Tuberculosis The Institute organises lecture and demonstration courses at home and overseas for doctors, and at home university centres for doctors, nurses, health visitors, social workers, and administrators Intensive three-day clinical courses for doctors are held throughout the year at King George V Hospital for Diseases of the Chest, Godalming, and East Fortune Hospital, Drem, East Lothian Short weekend lecture courses are arranged locally for general practitioners Particulars of courses may be obtained from the Secretary, Tuberculosis Educational Institute, Tavistock House North, Tavistock Square, London, W C 1

PROVINCES

Birmingham

The Board of Graduate Studies of the University of Birmingham provides a large number of extended and short intensive courses of instruction to help general medical and dental practitioners to keep abreast of recent advances Most of these are held at hospitals in Birmingham, but some are arranged at other centres, such as Coventry They endeavour to cover the needs of doctors and dentists practising in the West Midlands, but practitioners from further afield, particularly Birmingham graduates, are welcomed if they care to attend General medicine, general surgery, pædiatrics, obstetrics, neurology, neurosurgery, psychiatry, dental prosthetics, and general dental surgery are the main subjects covered In arranging these facilities the Board of Graduate Studies works in close cooperation with the Midland Faculty of the College of General Practitioners and the Central Counties Dental Postgraduate Committee

The Institute of Accident Surgery, which is affiliated to the Board of Graduate Studies of the university, holds short intensive courses in traumatic surgery at the Birmingham Accident Hospital Some are planned to help surgical consultants and trainees, some are for industrial medical officers and nurses, and others are for general practitioners Each year a five-day course in industrial ophthalmology is held at the Birmingham and Midland Eye Hospital

The University of Birmingham does not grant any medical diplomas and its doctorates of medicine and philosophy and its mastership of surgery are only given for theses providing a substantial advance in knowledge Graduates of universities other than Birmingham must have pursued original work in the Birmingham Medical School or in its teaching or affiliated hospitals for a minimum period of two years before submitting such theses The only courses of instruction for higher diplomas are for the diploma in psychological medicine of the Conjoint Boards (parts I and II in alternate years) and the M R C P (every one or two years) Facilities for parts I and II of the D M R D and D M R T are, however, available to those holding trainee appointments in the teaching hospital Attachments as observers and research-workers in the medical school and teaching hospital are arranged for large numbers of postgradaute students from other centres in England and from abroad, but no financial support can be offered and the expenses of all such attachments have to be met by outside sponsoring bodies or by the student himself The Board of Graduate Studies, in conjunction with the University Department of Social Medicine, pursues a number of research projects in which the help of general practitioners is invoked The chairman of the Board of Graduate Studies is Dr A G W Whitfield, The Medical School, Birmingham, 15

Bristol

The degrees of doctor of medicine (M D), master of surgery (CH M), and doctor of philosophy (PH D) are open to graduates of other universities, but to only those candidates who have pursued original research in the university for not less than two years In effect, this regulation means that these higher degrees are open to only those graduates of other universities who hold appointments on the staff of the university or of one of the Bristol hospitals The university diploma in psychological medicine is in abeyance The university offers a diploma in public health, and a course will be held in the session 1958-59 A few postgraduates are accepted for training for the D M R D and D M R T (Conjoint) and arrangements can sometimes be made for suitable candidates to hold a part-time post in the Bristol hospitals while doing the course. A course in child health lasting three months usually begins in October of each year, but in 1958 the course will not be held. Refresher courses for general practitioners consist of Sunday morning lecture-demonstrations in Bristol and occasional intensive weekend courses at hospitals in various parts of the South-West region. A Board of Dental Studies has been established to organise and direct dental studies in the university. A postgraduate course in medical physics for science students has been instituted. A review of preregistration appointments has been undertaken to ensure that only house-officer posts which have the facilities necessary for sound postgraduate training are recognised for the purpose. A medical postgraduate dean has been appointed.

Cambridge

The School of Postgraduate Teaching and Clinical Research includes the departments of experimental medicine, human ecology, medicine, and radiotherapeutics. In the John Bonnett Clinical Laboratories, pathological and biochemical services of the United Cambridge Hospitals are provided by university teaching officers under the direction of the professors of pathology and biochemistry. Particulars of the research activities of the school are given in the departmental annual reports, which are published in the Cambridge University *Reporter* in February each year. Prof. J. S. Mitchell took up office as regius professor of physic in July, 1957, and among the proposals submitted to the University in association with his appointment were plans for the development of the facilities of the Postgraduate Medical School and the United Cambridge Hospitals, in collaboration with the East Anglian Regional Hospital Board. An important step in this direction was the appointment of Dr. Leslie Cole as dean of the Postgraduate Medical School in December, 1957. The attention of the Council of the Senate and the Hospital Authorities has been drawn to the urgent need for the provision on a site close to the radiotherapeutic centre of Addenbrooke's Hospital of a building to house an Institute of Postgraduate Medical Studies, with lecture rooms, laboratories, and study rooms, and to provide more permanent accommodation for the departments of medicine and radiotherapeutics, both of which are at present in temporary buildings.

Between October and July in each academic year special sessions are devoted to teaching by members of the consultant staff of the United Cambridge Hospitals. Other teaching activities include clinical or clinicopathological meetings held on the second Friday of each month during term which give an opportunity for general practitioners and others to meet the staffs of the teaching hospital and of the various departments of the medical school. One-day symposia on subjects of particular interest to general practitioners are held monthly on Saturdays throughout the academic year. These symposia usually take the form of lecture-discussions followed by case-demonstrations. To meet the needs of practitioners who are unable to leave their practices on Saturdays it is proposed to hold one or two Sunday meetings during the coming year. During the summer of 1959 it is planned to arrange a longer course for general practitioners, from July 6 to 11 at Addenbrooke's Hospital. Accommodation and board will be provided in Downing College. Residential courses in midwifery are available for undergraduate and postgraduate students at the Maternity Hospital. All postgraduate courses and symposia are open without fee, subject to the terms of the Ministry of Health scheme, to practitioners who are under contract with an executive council of the National Health Service, and who have not less than 500 (or in the case of a rural practice 250) persons on their N.H.S. lists. Practitioners who do not qualify for a grant under the Ministry of Health scheme may be charged fees at rates corresponding to those which otherwise would have been payable by the Ministry. A course on Progress in the Biological Sciences in Relation to Dermatology has been arranged from Sept. 22–27, 1958. The course will consist of a number of half-day sessions each devoted to a group of papers on the same or related subjects. The course is designed primarily for those engaged in the clinical practice of dermatology but is open to any medically qualified person interested in the subjects under discussion. Courses are also contemplated on anæsthesia, diabetes, psychiatry, metabolic aspects of disease, and dental surgery. Further details of postgraduate facilities may be obtained from the Secretary of the Medical School, Tennis Court Road, Cambridge.

Durham

The part-time course for the diploma in public health ended in June. Seven of the eight candidates obtained their diplomas. The next course will begin in January and extend over five academic terms until June, 1960. Refresher courses for general practitioners were held during the year. These consisted of intensive weekend courses in medicine, pædiatrics, psychiatry, and obstetrics, and extended courses consisting of several afternoon sessions in various subjects. A number of local practitioners attended two-week resident courses in obstetrics in the Princess Mary Maternity Hospital. Postgraduate instruction in anatomy, physiology, pathology and bacteriology, and other subjects is always available by arrangement with the professors of the departments concerned. Several postgraduate students from overseas have been provided with suitable courses and research facilities leading to higher degrees.

Leeds

The University of Leeds grants two postgraduate diplomas, the diploma in public health and the diploma in psychological medicine. Both are now part-time courses, that for the diploma in public health being five terms. The course for the diploma in psychological medicine covers eight academic terms. Extended refresher courses for general practitioners, comprising one half-day session a week for six weeks, and weekend refresher courses on special topics are arranged from time to time both in the teaching hospitals and in regional hospitals. The secretary of the postgraduate committee is Dr. T. A. Divine, School of Medicine, Thoresby Place, Leeds, 2.

Liverpool

Postgraduate courses have continued as in previous years. Out of a total of 716 students in the medical school, 205 are postgraduates, 16 attended the course in general surgery, 19 in orthopædic surgery, 15 in public health, 11 in anæsthesia, 12 in psychological medicine, 25 in radiodiagnosis, 7 in radiotherapy, 4 in venereology, 67 in tropical medicine and hygiene and 22 the part-time M.R.C.P. course recently established. The course in general surgery is suitable for candidates who have already passed the primary examination for the F.R.C.S., but candidates for the course in orthopædic surgery must already hold the F.R.C.S., to become eligible to take the examination for the M.CH.ORTH. degree. The courses leading to the D.M.R.D. and D.M.R.T. extend over two years, candidates are usually found registrar appointments during the second year. In the course in anæsthesia, students are found appointments in recognised general hospitals to gain practical experience. Further information regarding university postgraduate courses may be obtained from the dean of the faculty of medicine.

The Liverpool School of Tropical Medicine offers a course of instruction for the diploma in tropical medicine and hygiene granted by the University of Liverpool. Two such courses are held each year, starting in the middle of September and the beginning of January and continuing for approximately three months. Only those students who hold a medical qualification registrable in the United Kingdom or otherwise recognised by the University, and who have attended the approved course of instruction in this school, are eligible to sit for this diploma. The school also provides courses in parasitology and entomology for students taking the diploma in public health granted by the University of Liverpool. Courses of instruction in veterinary parasitology and entomology are given during each academic session to Liverpool University undergraduates taking the M.R.C.V.S. diploma and B.V.SC. degree.

Manchester

Courses in preparation for the diplomas in psychological medicine, public health, radiodiagnosis and radiotherapy have been held during the past session and will be offered in 1958–59 A one-year course in medical statistics is available, but the course for the diploma in bacteriology will not be conducted during the session 1958–59 Refresher courses in industrial health have been held, and a series of lecture-demonstrations for general practitioners, given in conjunction with the College of General Practitioners, was very successful A similar series will be held on alternate Sunday mornings during the Michaelmas Term, 1958 The Dean of Post-Graduate Medical Studies is Mr R L Newell, F R C S , who is available for consultation by appointment

Oxford

The university committee responsible for postgraduate medical studies was recently reconstituted and its duties made the subject of a new university statute The first duties of this committee are to meet the obligations imposed upon the university by Act of Parliament—namely, keeping general practitioners informed of the latest developments in professional knowledge, and approving hospitals and posts therein for preregistration purposes Facilities for postgraduate medical studies are available in the Nuffield professorial departments of the university under the professors of medicine, surgery, obstetrics and gynæcology, anæsthetics, and orthopædic surgery Certain clinical appointments on the staff of these departments are open to specialist trainees from the Commonwealth In addition to the provision made in these departments for the training of specialists, there are approximately 20 trainee appointments in the teaching hospitals (the United Oxford Hospitals) and 11 in certain departments of selected non-teaching hospitals of the Oxford region These appointments (senior registrars) are in the following branches of medicine general medicine, pædiatrics, psychological medicine, chest diseases, pathology, general surgery, orthopædics and accident services, otolaryngology, ophthalmology, obstetrics and gynæcology, neurosurgery, plastic surgery, dental surgery, and radiology 6 of these are " paired " posts, the holders of which spend part of their period of training in a teaching hospital and part in a non-teaching hospital by mutual agreement Facilities for the continuing education of general practitioners are provided in hospitals at Oxford, Reading, Aylesbury, Stoke Mandeville, and Northampton Most departments of the United Oxford Hospitals may be visited by general practitioners on certain days throughout the clinical year (September to July) Practitioners may follow either an intensive course of a week or a fortnight (when programmes are arranged to suit individual requirements) or an extended course spread over a number of weeks or months In addition special short courses can be arranged for general practitioners All inquiries should be made to the Director of Postgraduate Medical Studies, Osler House, 43, Woodstock Road, Oxford, from whom further details of long and short courses may be obtained

Sheffield

The recently resuscitated D P H course was successfully concluded this session, but for various reasons another course is not to begin at once The development of the department of psychiatry has enabled the department to become increasingly a focus for regional postgraduate education in this specialty Other postgraduate activities include an experiment in which the usual intensive refresher course for general practitioners is being held in the hospitals of the Nottingham area instead of in Sheffield as in past years

WALES

Cardiff

Regular courses are conducted for the D P H (Wales), commencing in October every other year, and for the diploma in tuberculosis and chest diseases (D T C D) (Wales) (January to June each year) A special short course in tuberculosis is also held each year Prospectuses are available for these courses During terms, departmental provision is made for postgraduate teaching A standing arrangement also exists between the medical school (through its professorial departments), the teaching hospitals, and the regional board for regional consultants to spend short periods in Cardiff Special courses for general practitioners are arranged in association with the Welsh Board of Health—two short courses of 5 sessions each on selected subjects extending over one week in the autumn, and a fortnight's general course in the spring In addition, four weekend postgraduate courses in dentistry are being held for dental practitioners, and in these the regional hospitals most willingly cooperate Further information may be obtained from the Dean of Clinical and Postgraduate Studies, Medical School Office, 34, Newport Road, Cardiff

SCOTLAND

Aberdeen

Fortnightly refresher courses are held each year, mainly for general practitioners, which cover recent advances in medicine, surgery, obstetrics, pædiatrics, and other specialties From time to time extended courses of eight or ten weekly afternoon meetings are held There is also occasionally a Sunday-morning course for general practitioners when they can attend two lectures each Sunday for seven weeks, on subjects in medicine, surgery, pædiatrics, and midwifery The main postgraduate training is that given to registrars in all the departments of medicine In these posts registrars are rotated round the different wards and hospitals in their own specialty, and also they may spend periods in related departments A surgical registrar, for example, may go round the general surgical wards of the region but may also receive training in thoracic surgery, neurosurgery, orthopædics, pædiatric surgery, and otolaryngology In the same way a medical registrar may act for a time in a similar position in the children's and fever hospitals

Edinburgh

Postgraduate teaching in Edinburgh is arranged by the University in collaboration with the Royal College of Physicians and the Royal College of Surgeons of Edinburgh The courses are administered by the Edinburgh Post-Graduate Board for Medicine and cover the subjects of internal medicine, surgery, and basic medical sciences, in addition to refresher courses for general and dental practitioners Two courses in internal medicine, lasting twelve weeks, start in April and October each year These courses comprise lectures, lecture-demonstrations, clinical teaching, and clinical-pathological demonstrations, they are suitable for graduates wishing to specialise in medicine or who require a refresher course in the current outlook on internal medicine Two courses in surgery are held each year, starting in March and October These courses last twelve weeks and provide coordinated instruction in general surgery and in the specialist branches of surgery Clinical teaching in the wards of the Edinburgh Royal Infirmary and other general and specialist surgical units in the city has been arranged Graduates are thus able to spend a period in each unit, following the work of the department and obtaining systematic instruction A comprehensive course in the medical sciences of anatomy, physiology, pathology, bacteriology, and biochemistry is held in the summer, three hundred hours of instruction are given in this course, over a hundred of which are devoted to practical teaching, including work in an anatomy department This course is suitable for those requiring a final preparation in these subjects It is desirable that those taking this course should already have considerable basic knowledge Similar basic-science courses of ten weeks' duration, starting in October and March, are organised by the Royal College of Surgeons under the ægis of the Post-Graduate Board From July to September a course in clinical medicine is arranged in which clinical instruction in small groups is given in the teaching medical units in Edinburgh For those already holding higher qualifications short intensive courses in special subjects are held from time to time The numbers on these courses are limited so that discussion can be free Through the Director of Post-Graduate Studies, postgraduate students may be attached for clinical duties to the medical and surgical units in Edinburgh Preference is given to those who have attended the courses

The fourteen-day general-practitioner course, held in May each year, provides teaching either at the bedside or by means of lecture-demonstrations Emphasis is laid on recent advances in treatment, and free discussion, as well as constructive criticism by members of the course, is encouraged Instruction for local general and dental practitioners is arranged throughout the autumn term In addition, courses of one day's duration, on selected subjects, are held at intervals throughout the year Courses are often booked up several months in advance, so those intending to apply should do so early Applicants should write, giving particulars of their medical qualifications and postgraduate experience, to the Director of Post-Graduate Studies, Surgeons' Hall, Edinburgh, 8

Glasgow

Glasgow University Post-Graduate Medical Education Committee, representing the University and the Royal Faculty of Physicians and Surgeons of Glasgow, is offering the following courses during the coming session A nine weeks' part-time course in anatomy, physiology, biochemistry, pathology, and bacteriology will be held, as in previous years, from October to December The course is suitable for candidates preparing for the primary examinations for the surgical fellowships, and will provide a total of approximately 180 hours of instruction The course is organised primarily for the junior staff of hospitals in the Western Region of Scotland, but it is also open to other applicants A modified form of the course is available for trainees in anaesthetics reading for the primary examination of the F F A Clinical attachments to teaching units of one to three months' duration can be arranged in general medicine, general surgery, and various specialties for those proceeding to higher qualifications An annual course for the diploma in public health is available and a course for the diploma in industrial health will be arranged in any year in which there are sufficient applicants Short courses in other specialties are arranged when the demand arises and are advertised in the medical journals For the ensuing session a three weeks' course in mental deficiency and two weekend courses in chemotherapy have already been arranged The department of psychological medicine will hold a part-time course, extending from January to June, 1959, for candidates reading for the D P M Training in radiodiagnosis and radiotherapy, recognised for the D M R D and D M R T is available At least two refresher courses for general practitioners are held each year A very successful addition to the range of postgraduate courses has been the institution of short intensive courses on the use of radioactive isotopes These courses are organised by the staff of the regional physics department, which advises and assists hospitals on matters concerned with isotopes and electronic apparatus

St Andrews

Under the postgraduate training programme in the university a new combined clinical and medical sciences course will be held in Queen's College, Dundee, from October, 1958, to March, 1959 Those who have been accepted for this course will have a clinical attachment in a special subject of their choice and a supervisor who will guide their reading and laboratory work in relation to their specialty All the postgraduates will attend the medical sciences course A new postgraduate course in anatomy and physiology will also begin in October in the preclinical departments of St Salvator's College The director of postgraduate education is Prof R B Hunter, F R C.P E, department of pharmacology and therapeutics, Queen's College, Dundee

IRELAND

Dublin

The only postgraduate course of the University of Dublin at present available for other than Dublin graduates is that for the diploma in gynaecology and obstetrics The number of places in the course has been limited to 15 The examination for the diploma in psychological medicine is now open to graduates of other universities Last year a clinical postgraduate course, restricted to Dublin graduates, was given at the end of the long vacation, the course was very successful and a similar course will be given this year

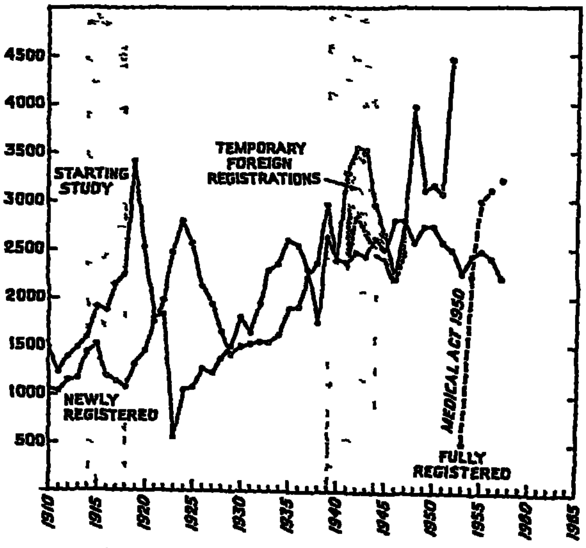
The National University of Ireland awards diplomas in public health, psychiatry, and child health

REGISTRATION

No-one is a legally qualified medical practitioner unless his name appears on the Register kept by the General Medical Council In the field of medical education the Council has a statutory responsibility for ensuring that the courses of study and examinations for any qualification conferring a title to registration do not fall below a proper minimum standard The Council, through its Disciplinary Committee, is also responsible for discipline within the profession The Medical Act, 1956, regulates the constitution and functions of the Council and the procedure of medical registration and discipline The new Act superseded a great many statutory provisions that had preceded it The Act, and Orders and Regulations made under it, provide that a person will not be eligible for full registration until he has, after passing a qualifying examination, served as a house-officer in approved hospitals or institutions for twelve months During this period he would be provisionally registered

The approximate number of second-year students admitted to medical schools in the United Kingdom and in Ireland was 2725 during 1950–51, 2565 during 1951–52, 2494 during 1952–53, 2280 during 1953, 2437 during 1954, 2485 during 1955, 2415 during 1956, and 2192 during 1957

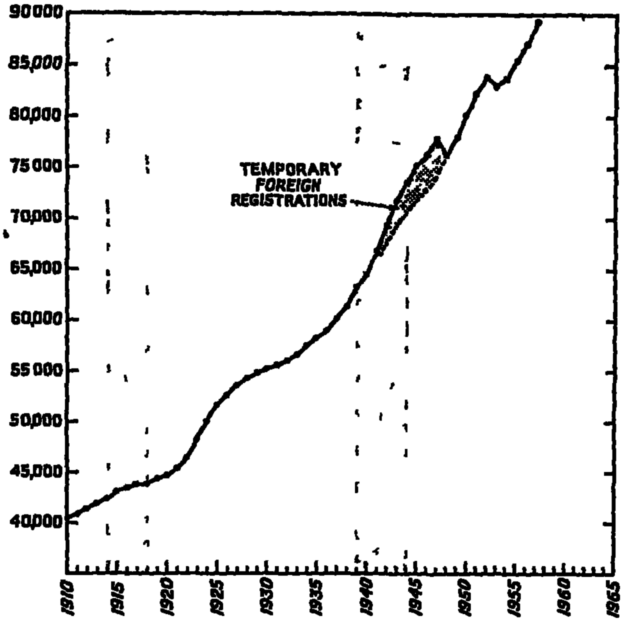
The numbers newly registered (including Commonwealth practitioners) were in 1951, 3075, in 1952, 4493, in 1953, 2320 (507 fully registered and 1813 provisionally registered), in 1954, 4542 (2222 fully registered and 2320 provisionally registered), in 1955, 5310 (2992 fully registered and 2318 provisionally registered), in 1956, 5522 (3113 fully registered and 2409 provisionally registered, and in 1957, 5455 (3226 fully registered and 2229 provisionally registered) The totals for 1954–57 include, of course, a considerable proportion of those provisionally registered in the previous year The widening gap between the number provisionally registered and those fully registered in recent years is largely due to the



Numbers starting study and registering *

---

* The numbers shown as starting study are taken from the Medical Students Register up to 1938, and since then from returns made by the medical schools to the General Medical Council Both forms of notification are incomplete for certain years Starting with 1953, the figure is based on the annual examination returns and covers the calendar year instead of the academic year as formerly



Number of fully registered doctors on the Medical Register

increasing number of Commonwealth practitioners who obtain full registration, without (except in a minority of cases) first applying for provisional registration

The number obtaining provisional and full registration in 1953 was much lower than in the preceding five years This is attributable to two things (1) some people who would normally have registered in 1953 took special steps to obtain registration before the end of 1952 in order to avoid the preregistration year, and (2) the lengthening of the curriculum at certain Scottish universities meant that fewer than usual qualified and became provisionally registered in 1953 The striking increase in the number of newly registered doctors in 1952 (4493 as against 3075 in 1951) was largely due to the addition of 1452 names to the Commonwealth List in 1952 (as compared with 471 in 1951)

The Defence Services

Royal Naval Medical Service

The Medical Service of the Royal Navy affords, to medical practitioners who are attracted by the prospect of sea service and work with the Royal Navy, a wide opportunity to practise their profession in an attractive environment A background of naval tradition naturally permeates the Royal Naval Hospitals and Naval Training Establishments, as well as Her Majesty's ships Officers serving on the permanent list are encouraged to specialise in all branches of medicine, and they are given full facilities to obtain higher qualifications Courses of postgraduate study are carried out not only in naval hospitals but also at civilian teaching centres There is a wide variety of subjects comprised in the title "naval medicine", and it might often be claimed that certain of these subjects are unique They include the physiology of diving, the physical aspects of service afloat and ashore, Commando service, tropical diseases, and industrial hygiene, an important further specialty is that of aviation medicine, and a small number of Naval medical officers undergo full pilot training before undertaking duties with the Fleet Air Arm or in research establishments Furthermore, a naval medical officer is no longer concerned with the care of the sailor alone, but must also have up-to-date knowledge of the diseases of women and children so that he may attend the needs of the W R N S, members of the Q A R N N S, Naval V A D s, and the wives and children of Servicemen and Admiralty personnel serving abroad

The Royal Naval Medical Service offers a life career with service on the active list up to 55 for all officers, to 57 for surgeon captains, and to 60 years of age for surgeon rear admirals Provision is made in the regulations for counting previous experience, both service and professional All previous commissioned service as a medical officer in one of the Armed Forces is allowed to count in full, and all non-medical commissioned service is allowed to count as half Civilian hospital experience, and also experience of a special nature in private practice which is recognised by the Medical Director-General as warranting additional seniority, may be allowed to count up to a limit of seven years in all

The additional seniority will be reckoned as service for pay and promotion but not for retired pay or gratuity Leave is granted to officers at the following scales in the United Kingdom, 42 days a year, when appointed to H M Ships on general service, at the rate of 3 days a month, when on foreign service, 14 days local leave a year with a further 2 days for each month abroad on return to the United Kingdom

Entry in the first place is for a short-service commission of either three or four years which may be extended During this time application may be made for transfer to the permanent list. Medical practitioners who undertake their National Service in the Royal Navy are also eligible to apply to transfer to the permanent list The normal career for a medical officer provides for promotion to the full rank of surgeon lieutenant after one year's service, and to surgeon lieutenant-commander after a further seven years' service Surgeon lieutenant-commanders are promoted to surgeon commander by selection at about their 15th year of total service and surgeon commanders are promoted by selection to surgeon captain about their 23rd year of total service Subsequent promotion to surgeon rear admiral is by selection

Rates of pay are as follows

Rank	*Pay per annum*
Acting surgeon-lieutenant	£657
Surgeon lieutenant	£766–£1053
Surgeon lieutenant-commander	£1295–£1569
Surgeon commander	£1660–£1931
Surgeon captain	£2080–£2363
Surgeon rear-admiral	£3029
Surgeon vice-admiral	£3759

Additional allowances are granted to married officers according to rank When the officer is not accommodated or messed, additional allowances are paid

Medical officers are also eligible for allowances, in addition to the basic rates of pay, on the same scale and under the same conditions as for other officers of equivalent rank These include travelling expenses, subsistence allowance, and passages for wives and families Officers who transfer to permanent commissions after a minimum of one year's service will be paid a permanent commission grant of £1500 (taxable)

The maximum rates of retired pay in addition to terminal grants are payable to officers who complete certain specified periods of service Officers allowed to withdraw who are ineligible for retired pay will be eligible to receive gratuities

Further information may be obtained from the Medical Department, Admiralty, Queen Anne's Mansions, St James's Park, London, S W 1

ROYAL NAVAL DENTAL SERVICE

Dental officers are entered for Naval service under similar conditions to those applying to medical officers Information concerning conditions of service can be obtained from the Medical Department of the Navy, Queen Anne's Mansions, St James's Park, London, S W 1

Royal Army Medical Corps

There is, at the moment, a limited requirement for trained specialists, particularly ophthalmologists, otolaryngologists, and radiologists In the main, however, the R A M C seeks applications from young recently qualified practitioners

Non-specialist Career

66% of medical officers will be employed on general practitioner duties After attending the junior officers' course at the Royal Army Medical College, they serve 2 years as officer in medical charge of a unit with concurrent part-time duties in a military hospital where they become conversant with the soldier and his environment, the objects of the

Army, and the requirements from its medical service in peace and war They will, later, serve overseas where, as a regimental medical officer or in charge of troops and families, a reception station or small hospital, or in field medical units they will be able to study the causation, prevention, and treatment of tropical diseases, the effects of climate, &c On their return, they attend the senior officers' course, the first 2½ months are spent in study at the Royal Army Medical College, Millbank, and the next 3 months in a special postgraduate course at a London teaching hospital At this stage officers may opt to remain at general medical duties or take up field training or junior staff appointments For the more senior ranks the requirements are a sound background of clinical and preventive medicine to meet their advanced responsibilities in the administration of the Army Medical Services in peace and war

Specialist Career

Specialists are, subject to professional proficiency, employed on specialist duties up to the rank of colonel Thereafter they may serve in this rank up to the retiring age of 57 or may be selected for promotion to brigadier either in a specialist or non-specialist capacity The process of selection for specialist training is carried out after the junior officers' course, those applicants who are most successful in the course examination being accepted Those accepted are provided with excellent opportunities to obtain higher qualifications and specialist experience

Postgraduate Training

There are liberal arrangements for specialists and non-specialists to undergo postgraduate training throughout their career

Employment after Retirement

All suitable medical officers (specialist or non-specialist) may be employed up to the age of 65 in appointments specially set aside for retired officers Non-specialists are employed on general practitioner or medical administrative duties and specialists on specialist duties

Conditions of Service

As conditions of service greatly affect a wife, married practitioners considering an Army career are advised that their wives should discuss these conditions with Army wives who have served at home and overseas

The *overseas tour* is of 3 years' duration Families of officers aged 25 or over can, in the case of most overseas stations, accompany the officer by sea or air Local allowances are paid in certain overseas areas where the cost of living is greater than in the United Kingdom Schools are normally available locally, and in the case of those with children between 11 and 18 years left in the United Kingdom a tax-free education allowance of up to £75 per year for the first child, £100 for the second child, and £125 for the third and subsequent children, is paid if they attend boarding-school, or £35 a year if they attend day school and are placed in the care of a guardian These allowances will also be payable for children undergoing vocational and technical training The facilities for sport and leave travel vary but are usually very good

A *home tour*, spent in U K or North-West Europe, lasts at the moment 4–5 years As a rule there is no difficulty in obtaining family accommodation or arranging schools The education allowance referred to above is, however, subject to income-tax in the case of those serving in U K, but not in North-West Europe

It is the Army policy that all ranks should be given some months' warning of an impending move This is done as much as possible but cannot always be achieved—for example, the posting of an officer after the senior officer's course may be influenced by his performance on the course and cannot be decided beforehand, and emergencies may necessitate a sudden chain of appointments and reliefs

Married officers over 25 years of age are allowed, subject to certain conditions, travel at public expense for their family from duty station to duty station on posting, or to a selected place of residence if accommodation is not available at the new duty station Those serving on a commission of three years or over may also be eligible for refund of furniture-removal expenses, disturbance allowance of £40 or £20 (according to the type of accommodation occupied) designed to cover incidental expenses when the family are required to move for service reasons, and, when serving overseas with their family, refund of furniture-storage charges

Family accommodation provided by the Government is at a reasonable rent—furnished accommodation for a major is, for example, £180 per year

The comradeship of the Army extends to wives and children, but the wives of those interested will find out about this and the advantages and disadvantages of an Army life far better from other Army wives

Conditions of Commissioning

The normal maximum age is 33 but allowance is made for those who have previously held commissioned rank in H M Forces on full pay An antedate, counting towards pay and promotion, may be allowed for 2 years spent in civilian practice or hospitals An additional period of up to 5 years may be allowed for specialist appointments held An allowance is also made for previous commissioned service on full pay This antedate counts towards the "reckonable service" mentioned below

Promotion and Pay

Details are given in the accompanying table In addition the following are payable

On appointment to a permanent commission, a taxable grant of £1500

Officers are entitled to an initial outfit allowance in addition to certain free issues of clothing, so that they may provide themselves with the authorised scale of uniform without expense to themselves In addition, a tropical-kit allowance is granted to officers on first posting to stations for which tropical kit is authorised These allowances are tax-free Relief from income-tax on necessary expenditure on maintenance of uniform, estimated at £40 a year, is admissible annually

Junior specialist pay	£73 per year
Senior specialist pay	£219 per year
Qualification pay (for Staff College graduates)	£63 to £127 per year

PROMOTION AND RATES OF PAY OF R A M C MEDICAL OFFICERS

Rank	Promotion	Pay	Marriage allowance (age 25 or over)			Ration allowance
			In married quarters	Out of married quarters	Under 25	
		£	£	£	£	£
Lieutenant	—	657	355	410	219	106 (not taxable)
Captain	1 year's reckonable service	766–1058	355	410	219	
Major	8 year's reckonable service	1295–1569	401	456	—	
Lieut -colonel	By selection after about 17 years	1660–1934	456	511	—	
Colonel	By selection after about 23 years'	2080–2244	456	511	—	
Brigadier	By selection	2354	520	574	—	
Major-general	By selection	3029	611	666	—	
Lieut -general	By selection	3759	611	666	—	

Retired Pay, &c

For less than 20 years' qualifying service, there is a tax-free gratuity rising from £1000 at 10 years' service to £2800 at 19 years' service

Pensions are payable as follows on retirement at the ages and with the reckonable service stated

Major	£625 for 22 years' reckonable service at 53 years, plus lump-sum grants of £1875
Lieut -colonel	£800 for 24 years' reckonable service at 55 years, plus lump-sum grant of £2400
Colonel	£1000 for 26 years reckonable service at 57 years, plus lump-sum grant of £3000
Brigadier	£1150 for 28 years' reckonable service at 59 years, plus lump sum grant of £3450
Major-general	£1400 for 30 years' reckonable service at 60 years, plus lump-sum grant of £4200
Lieut -general	£1600 for 30 years reckonable service, on completion of appointment, £4800

Deductions are made in the case of an officer whose reckonable service is less than stated above or who retired voluntarily 2 or more years before his compulsory retiring age

Retired-officer Appointments

These may be held from the date of retirement until the age of 65 The annual salary ranks from £1130 to £1400, in addition to pension

Further information may be obtained from the Assistant Director-General, The War Office (A M D 2), London, S W 1

ROYAL ARMY DENTAL CORPS

Registered dental surgeons of British nationality or citizens of the Irish Republic who are liable for service under the National Service Act may apply for short-service commissions for not less than 3 years on the active list, with a reserve liability up to 8 years from the date of their appointment Those (both men and women) *who are not liable for service may apply for short-service commissions* for varying periods of between 2 and 8 years on the active list An antedate of seniority counting towards increments of pay and time promotion may be granted for postgraduate civil professional experience, previous commissioned service in the Armed Forces is also taken into consideration A tax-free gratuity is payable Officers or dental surgeons (male) may be appointed to permanent commissions *direct or at any time during the short-service or National-Service* engagement Until further notice, those so appointed will be paid a special grant of £1250 (taxable) after one year's satisfactory service as dental officers The period of their short-service commissions will reckon towards ultimate retired pay and service gratuity, but will not entitle them to short-service gratuities Dental surgeons who are eligible to apply may obtain full particulars and application forms from the Under-Secretary of State, The War Office (A M D 6), London, S W 1

Royal Air Force Medical Branch

The Royal Air Force offers an attractive career to fully registered men and women medical practitioners who are British subjects or citizens of the Irish Republic Normally, the upper age-limit for applicants is 33, but older applicants may be considered Appointment is usually to short-service commissions for three, four, five, or six years in the first instance, each of which may be extended to complete a maximum period of eight years' service Exceptionally, suitable candidates may be appointed to permanent commissions direct from civil life Short-service officers may apply for permanent commissions at any time during their service

Medical officers come into contact with flying and air evacuation of sick and wounded, as well as the clinical specialties and the treatment of Service families There are, in addition, opportunities in aviation medicine, hygiene, and industrial medicine

For regular officers, antedates of seniority may be admissible for recognised civil experience These antedates reckon towards pay, seniority, and promotion The normal rank on appointment is flying-officer, with promotion to flight-lieutenant after one year's reckonable service, to squadron-leader after eight years' reckonable service, and to wing-commander after seven years' satisfactory service in the substantive rank of squadron-leader Officers recognised as R A F specialists will be promoted to the rank of group-captain after eight years' satisfactory service in the substantive rank of wing-commander, and to ranks above group-captain by selection Promotion to group-captain and above for non-specialist officers will be by selection

Officers serving on permanent commissions may be allowed study-leave with full pay and allowances to take approved postgraduate courses, for which tuition fees on an approved scale may be granted Officers having experience or aptitude in a specialty may be employed on specialist duties and subsequently earn recognition as junior specialists with additional pay of 4*s* per day and as Royal Air Force specialists with additional pay of 12*s* per day Non-specialist medical officers below the rank of group-captain will be awarded additional pay of 4*s* per day on gaining a registrable diploma in public health, industrial health, or tropical medicine, provided that in each instance the prescribed period of study occupied an academic year

Officers appointed to permanent commissions will receive a grant of £1500 (subject to income-tax) after one year's satisfactory service and they will be entitled to retired pay and other benefits after completion of service Short servic officers will, on completion of their commissions, be paid a *tax-free gratuity at the rate of £200* for each year of satisfactory service Arrangements exist to preserve their superannuation *rights under the National Health Service (Superannuatio* Regulations, 1950

Further information can be obtained from the Und Secretary of State for Air, Air Ministry, M A 1, 1–6, Tavisto Square, London, W C 1 (Euston 5040, ext 310)

ROYAL AIR FORCE DENTAL BRANCH

Commissions are available in the Royal Air Force Dental Bran to candidates of either sex who possess a degree or licence in den surgery of a British university or licensing board, and who a registered under the Dental Act in force in the United Kingdo Dental officers in the Royal Air Force have plenty of scope for the aspects of dentistry in a branch which trains its own technica and *maintains its own laboratories* under *senior dental office* Dental officers serving on short-service or National-Service co missions may apply at any time for appointment to permanent co missions The length of the period on a short-service commiss and the period required in the reserve on its completion is the sa *as for medical officers Similarly, dental surgeons may be gran* permanent commissions if they can complete at least twenty yea service qualifying for retired pay Previous commissioned serv counts for antedate of seniority rank on appointment, and terms promotion the same as for medical officers, while antedates for ci experience in a recognised professional appointment are given on t following basis, subject to a maximum antedate of seven years f *such experience first four years, in full, any later experience,* in ha Candidates who hold specialist appointments may be allowed have their civil experience assessed on a different basis, but with the same maximum of seven years A tax-free gratuity, at the rate £170 a year for each year of satisfactory active-list service, is payab *to short-service* officers on transfer to the *reserve* Dental office appointed to permanent commissions are encouraged to pursue the studies in postgraduate research and may be allowed up to seve months' study leave on full pay and allowances to take approv postgraduate courses Until further notice, a grant of £1250, subje to income-tax, will be made after one year's satisfactory commission service in the dental branch, to officers appointed to permane *commissions Short-service or permanent-commission* officers wh have the appropriate higher qualifications and the requisite experienc may be recommended for specialist appointments Further informa tion may be had from the Under-Secretary of State, Air Ministry M A 6, 1–6, Tavistock Square, London, W C 1 (Euston 504 ext *106*)

Health Services at Home

PUBLIC HEALTH

AMONG the divisions of the nation's health services, *publi* health ranks next in size and importance to the general practitioner *and hospital services and it offers a* satisfactory career to the young doctor keen to work for the welfare of the *community as well as for the individual*

Under the National Health Service Act of 1946, councils of counties *and* county boroughs *were* designated "local health authorities" and had conferred upon them, and through them upon their medical officers of health, wide responsibilities for the provision of personal health services These include a duty to provide clinics and other services for mothers and young children, domiciliary *midwifery*, home nursing, *domestic help* health visiting, immunisation, vaccination, and ambulanc services Wide powers are also given to these *authorities* to prepare and administer schemes for the prevention of diseas *and for the care and aftercare of sick persons* Recently, new concepts have been developing in the mental-health services *and there* will be considerable expansion in local-health authority responsibilities as the result of the recommendations in the report of the Royal Commission on the Law relating to Mental Illness and Mental Deficiency In most counties and county boroughs the medical officer of health *is principal* school medical officer and is thus responsible for the preventive health services covering children of all ages In some areas further coordination has been secured by placing the *authority*'s socia welfare services also under the medical officer of health. Under the Local Government Act of 1958, many of these health and welfare functions may now be delegated to the larger county district authorities.

In county boroughs, boroughs, and urban and rural districts, the medical officer of health is responsible for environmental hygiene. In contrast with the early days of public health when the medical officer of health was personally concerned with the execution of many sanitary duties, health departments are now organised to free him from much of the detailed work, which is performed by trained lay officers, or even transferred to the care of other departments—as in the case of water-supply and sewerage disposal. Naturally, the extent of this devolution of responsibility varies widely, and in rural areas problems of water-supply and sanitation are still a major concern of the medical officer of health. The supervision of housing conditions is also a responsibility of the health department. All this work remains under the general control of the medical officer of health, and he must supervise the purity of water-supplies even though their production is not his concern. Though less concerned with detailed work, supervision must be far wider than that exercised by his predecessor of a hundred years ago.

Control of infection has always been one of the principal functions of the medical officer of health. Laboratory workers have made great advances in the identification of species and strains of bacteria and viruses and new techniques applied to epidemic control have given the medical officer of health an instrument of precision in much of his epidemiological work. The application of specific prophylactic measures against various acute infections is now an important function of all health departments. Drastic reduction, if not the complete extinction, of many important infectious diseases has become a feasible target for all health departments.

Recent developments have increased the opportunities for the young medical officer to obtain a comprehensive training in public health. In the larger towns there are now more posts of senior-medical-officer grade, and in counties, schemes of divisional administration have been evolved. The work of the medical officer of health to a number of county district authorities is often combined with an appointment as assistant or divisional county medical officer of health. The holder of such a post obtains a detailed knowledge of the community under his care, and, while retaining a high degree of individual responsibility, he suffers none of the disadvantages of rural isolation.

A sound clinical background is an essential qualification for the new entrant and a course leading to the diploma in public health should be taken at an early stage since this qualification is necessary for anyone seeking an appointment as a medical officer of health. For doctors engaged in clinical preventive medicine a *diploma* in child health, in obstetrics and gynæcology, or in psychological medicine is an advantage.

Individual progress in a public-health career depends largely, if not entirely, upon the doctor's personal qualities, for, as adviser to his authority, the reputation of the medical officer of health depends on the soundness of the advice he gives. Quite apart from his statutory functions, he has an important part to play in promoting the health education of the community, and in helping to secure full coordination between the branches of the health service in his area. He is assisted by the regular liaison meetings, which are held in most regions, between the hospital boards and the county and county borough medical officers of health. Most hospital boards rely on the medical officer of health to determine the urgency of the social grounds for admitting patients to hospital, especially in maternity cases and when considering the chronic sick. Some medical officers of health have been appointed as members of hospital medical advisory committees or of hospital management committees, and, through the National Health Service Act, a closer relationship with the general-practitioner services has now become possible.

INDUSTRIAL MEDICAL SERVICES

INDUSTRIAL or occupational medicine is gradually taking its proper place among the branches of medicine. Whatever may be the merits or demerits of a classical education, it is certain that the social stigma placed by the ancient Greeks on the mechanical arts and trades led to the neglect of the working man in ancient medical practice and of the occupational diseases by medical science. Even now the influence of the classics on this aspect of medicine has not been entirely dissipated, and it is a rare physician who goes fully into the details of his patient's occupation and tries to estimate its effect on his health. This is surprising because there is no study more fascinating than that of the physical and mental reaction of man to his environment. Industrial medicine has both preventive and curative aspects but it is generally regarded as a branch of preventive medicine, and of public health in its wider sense, or even of the loosely defined concept of social medicine.

In November, 1954, the Minister of Labour and National Service announced in the House of Commons that he had decided to take steps to stimulate the further development of industrial health services in work-places covered by the Factories Acts. He later set up a standing industrial health advisory committee to carry out a review to ascertain where industrial health services most needed to be extended. Two pilot surveys have been undertaken—one in Halifax and the other in Stoke-on-Trent—and the results of the Halifax survey have now been published.

It is to be hoped that the deliberations of the industrial-health advisory committee will lead to the creation of more posts for doctors interested in occupational medicine. These posts fall into various categories, such as those in the Civil Service, the nationalised industries, research organisations, the universities, and factories. But, though the importance and opportunities of industrial medicine are increasingly recognised, it cannot yet be said that in salary or prospects the openings in this work are always as favourable as those in the National Health Service. For industrial posts within the Civil Service, the prospects have improved slightly as a result of the Royal Commission on the Civil Service, but even at present this service does not offer enough senior appointments to assure promotion to all who earn it. Moreover, as things are at present, the top posts in the medical Civil Service are often filled by doctors who previously held appointments outside the service, and this is a discouragement to those who are contemplating entry through the basic grade.

The appointments as medical officers to factories and other industrial organisations vary in attractiveness, both as regards opportunities and salaries. In some the conditions and prospects are good, and the British Medical Association has laid down a scale of minimum salaries.

The main Government department supervising the health of industrial workers is the Factory Department of the Ministry of Labour and National Service. This department, which up to 1940 worked under the Home Office, dates from 1833 and administers the Factories Acts (1937 and 1948) with regulations on accident and sickness prevention, hours of work, amenities, and canteens. The inspectorate numbers about 412, of whom 18 are doctors. Members of the department, whether lay or medical, take part in the activities directed towards the prevention of illness and maintaining the health of the factory population. The medical inspectors are stationed in London, Birmingham, Sheffield, Liverpool, Cardiff, Manchester, Glasgow, and Leeds, and from these centres they are able to deal with factory health and conditions in any part of the country. Under them 1750 general practitioners give part-time service as appointed factory doctors (previously called examining surgeons), examining all young entrants into industry, and periodically all those engaged in specific dangerous processes. In addition there are about 400 doctors employed whole-time in factories or groups of factories, and about 3000 (may be more) in part-time work. An interesting development in recent years has been the setting-up of medical services for looking after workers on trading estates. Three such schemes, at Slough, Hillington, and Bridgend are well established and others are projected to serve the trading estates at some of the "new towns" One such service is now in operation at Harlow in Essex It has been a common criticism of the industrial medical services that the workers at small factories are not catered for, and these group services might well form a model for a national service It is well to bear in mind, however, that even in factories where there are no doctors a close watch on conditions is maintained by the Factory Department

Apart from the Factory Department, other Government departments deal with various aspects of the industrial medical services For instance, the Post Office, which employs more workers than any other department, has had a medical service since 1855, and since it deals with engineering and manual workers in addition to office staffs, it is partly an industrial medical service The Post Office medical staff is now directed by the chief medical adviser to the Treasury, who has in addition a staff of 15 doctors which deals with the health problems of the Civil Service The inspectorate of the Ministry of Fuel and Power has a medical section with a few full-time medical inspectors The National Coal Board provides a comprehensive industrial medical service and research programme for the industry which now has a large staff of whole-time doctors The Ministry of Supply Medical Service with 40 doctors deals with the health of the workers in the Royal Ordnance factories, and in the research stations The Ministry of Pensions and National Insurance has a medical staff both at headquarters and in the regions, which advises on compensation for industrial injuries as well as for other causes of ill health The former silicosis and asbestosis board is now a part of the medical service of the Ministry On the staff of the pneumoconiosis medical panels, as they are now called, are some 37 whole-time medical officers who deal with the diagnosis and certification for compensation of cases of silicosis, asbestosis, and some other forms of pneumoconiosis They also carry out periodical medical examinations of workers engaged in some scheduled occupations in which cases of pneumoconiosis are likely to arise The centres from which the panels work are Swansea, Cardiff, London, Manchester, Sheffield, Stoke-on-Trent, Bristol, Birmingham, and Edinburgh Some of the newly nationalised industries have established medical services—for example, the London Transport Executive, a part of the British Transport Commission The London Transport Executive employs a chief medical officer with 9 full-time doctors The National Dock Labour Board also has a medical service consisting of 7 full-time medical officers and 1 part-time medical officer Some, but not all, of the regional boards of the nationalised gas industry have appointed whole-time and part-time doctors to look after the health of the workers

In addition to investigations and research into industrial diseases conducted by medical inspectors of factories, mines medical officers and works doctors, much fundamental research into environmental conditions has been carried out by the various departments of the Medical Research Council Clinical and field studies made under the ægis of the council's industrial pulmonary diseases committee include inquiry into the pneumoconiosis of coalminers and the byssinosis of cotton workers The London Hospital department for research in industrial medicine was established in 1943, and a few years later, in conjunction with the Ministry of Fuel and Power, a bureau for research into pneumoconiosis and other diseases was set up Other units of the council dealing with industrial health include the toxicological research unit at Carshalton, the groups for research in industrial and applied psychology in Cambridge, and London, and the industrial injuries and burns research unit at the Birmingham Accident Hospital There is also a unit for research on climate and working efficiency at the department of human anatomy at Oxford, a social medicine research unit at the London Hospital, and a statistical research unit at the London School of Hygiene and Tropical Medicine Problems on the health aspects of atomic energy are being dealt with at Harwell Research into industrial health matters is also being undertaken by the university departments mentioned below

The Institute of Social Medicine at Oxford, which works under a joint board, also undertakes investigations into various aspects of industrial health At the London School of Hygiene and Tropical Medicine, the Rockefeller Occupational Health Unit was established in 1956 University chairs devoted to industrial or occupational medicine have been set up at Manchester and Durham The chair of social medicine at Birmingham includes industrial medicine within its terms of reference and the University of Sheffield has appointed a professor of social and industrial medicine Students are likely to hear more about these subjects in their undergraduate courses Postgraduate courses are held in London, Birmingham, Sheffield, and Manchester, and occasionally at other centres Diplomas in Industrial Health (D I H) have been instituted by the Society of Apothecaries, the Conjoint Board of the Royal Colleges of Physicians and Surgeons, and the Faculty of Physicians and Surgeons of Glasgow The Association of Industrial Medical Officers was formed some years ago by doctors interested in industrial health, and branches have been established in various parts of the country, the *British Journal of Industrial Medicine* is sponsored by this association in conjunction with the British Medical Association The association has also since April, 1951, published a quarterly journal, called the *Transactions of the Association of Industrial Medical Officers*, which is devoted to the dissemination of information about the practical arpects of industrial medicine rather than to original research

PRISONS AND BORSTAL INSTITUTIONS

THE medical service is a part of the general-service class of the medical Civil Service, under the immediate control of the Director of Medical Services at the Prison Commission The work is mainly clinical and the medical officer is responsible for the physical and mental welfare of the inmates, a responsibility which extends to a general oversight of the hygiene of the establishment in which he is working The service is expanding to meet the needs of a rising inmate population and the increased demands of present-day methods It offers an attractive career to medical practitioners who are interested in the various problems connected with crime and the understanding and treatment of criminals The medical and surgical cases seen are comparable with those met with in outside practice The various establishments have their own hospital accommodation, a large prison, for example, may well have a hospital with up to 100 beds The doctor in a prison or borstal is a member of a team whose efforts are directed towards the rehabilitation of those committed to its charge On the medical side the aim must be not only to attend to ordinary day-to-day medical care but to discover, and if possible to remedy, disabilities and maladjustments which hinder the training of the offender and make it more difficult for him to regain a place among law-abiding citizens Although not a member of the National Health Service the prison medical officer maintains a close liaison with the hospital and specialist facilities of that service, and thereby gains much both for his patients and himself by contact with advances in medical knowledge and procedures

There are now over seventy establishments under the control of the Prison Commissioners, and as is to be expected, they vary very much in their size and purpose depending on the class of inmate, and the medical requirements differ accordingly At the larger establishments the medical work is in the hands of whole-time medical officers, whereas the small institutions are served by part-time doctors who are usually local general practitioners The more important prisons may have as many as four or five full-time medical officers, together with psychologists and psychological testing assistants At a few prisons there are also psychiatric social workers Principal and senior medical officers have advisory and other duties in connection with small groups of establishments The medical officer is called upon to make medical and psychiatric reports to the Commissioners from time to time In remand prisons the preparation of reports to court and the giving of verbal evidence, particularly in regard to the mental condition of offenders, are important aspects of the work Postgraduate experience in psychiatry is therefore an advantage. Surgical and psychotherapeutic units are established at selected centres where the work is undertaken mainly by visiting specialists working on a sessional basis and in close association with the regular medical staff

The national scales, in accordance with the general Civil Service scales, are

Medical officer*	£1690 rising by seven annual increments to a maximum of £2300
Senior medical officer	£2650
Principal medical officer	£2950

* Linked to aged 35 minus £45'50 for each year below that age, and plus one increment for each year above 35 up to 40 years of age.

Officers serving in London receive £40 to £50 a year more, and until 1962, officers in certain provincial areas receive slightly less than the national rate

The appointments are pensionable, without contributions being required, and on retirement normally a pension and lump-sum gratuity are payable There is also a contributory widows' and children's pension scheme. Pensionable service under the National Health Service and established Civil Service may be aggregated for pension Unfurnished quarters, when available, are provided at a moderate rental

Permanent appointments are made by the Civil Service Commission, 6, Burlington Gardens, London, W 1, to whom inquiries for such appointments should be addressed On occasion temporary full-time appointments are available and for such appointments as well as for part-time appointments particulars can be obtained from the Prison Commission, Horseferry House, Dean Ryle Street, London, S W 1

Services Abroad

HER MAJESTY'S OVERSEAS CIVIL SERVICE MEDICAL BRANCH

THE medical departments of the Governments of the territories overseas for which the Secretary of State for the Colonies is responsible offer a wide range of openings to the right type of doctor There is a large field of medical opportunity in these territories and whatever political future they may have, there is no doubt that they will require the help and advice of British medical men for many years to come The work of a medical officer overseas is many-sided and requires a doctor of all-round capabilities There is an immense and fascinating field of clinical work, but the doctor must be prepared to occupy himself with a good deal of public health and social medicine. He must, of course, be ready to work with non-European colleagues and although the actual conditions of life and work vary greatly from territory to territory, life abroad has many pleasant features and often gives more scope for individual responsibility than life in Britain.

Vacancies occur in many parts of the world The greatest number is in tropical Africa Candidates must ordinarily be British subjects holding medical qualifications registrable in the United Kingdom, and should normally be under 45 years of age In some territories permanent appointments are available Candidates selected for permanent appointments become members of the medical branch of Her Majesty's Overseas Civil Service Many future appointments are likely to be made on the basis of short-term contracts, usually renewable, and carrying a generous gratuity on termination Doctors in the National Health Service may take temporary appointments overseas up to six years without loss of pension rights

In the first instance medical officers are usually appointed for general duties, which require a balanced outlook upon both preventive and curative medicine Such duties often involve the charge of a district hospital' and responsibility for the medical administration of a district Although many officers are employed on clinical duties in the large hospitals, some posts are purely concerned with public-health work and for these the possession of the D P.H is generally necessary

There are many specialist appointments which, if permanent, are normally filled from within the service by officers possessing the necessary aptitude, experience, and qualifications, wherever they may be serving Senior administrative appointments are filled by the promotion of serving officers whose opportunities are not necessarily confined to the territories in which they are serving.

Officers possessing qualifications or experience in pathology can be considered for appointment to the laboratory establishments Workers in the laboratories carry out pathological and biochemical examinations for clinical, forensic, and public-health purposes

There are a number of posts for women doctors, particularly for those with special experience in obstetrics, school health, child welfare, and nutrition, although their employment is not necessarily confined to these subjects

Salaries vary considerably from territory to territory in accordance with local conditions Some existing salary scales for medical officers are

	£
Nigeria	
Federation	1128–1950
Northern	1212–1950
Eastern	
Western	1056–1950
Sierra Leone	1248–2046
Gambia	1128–1950
Kenya	1284–2115
Uganda	
Tanganyika	
Hong-Kong	1305–2484
North Borneo	1470–2324
Sarawak	
Fiji	F1050–2000
Jamaica	900–1600

Specialists and senior administrative officers receive super-scale salaries ranging broadly from £2300 to £3075 and in many territories there are cost-of-living allowances and allowances for children's education. Passages are free and quarters are usually provided at a low rental Leave is generous and officers pay income-tax at local rates, mostly much lower than those in the United Kingdom Private practice is allowed to a limited extent in some territories, according to local regulations

It is impossible here to give more than a brief outline of medical appointments in the territories overseas and candidates are advised to seek fuller information from the Director of Recruitment, Colonial Office, London, S W 1

FEDERATION OF RHODESIA AND NYASALAND

THE Federal Government administers the health services of Southern Rhodesia, Northern Rhodesia, and Nyasaland. The rates of pay for full-time officers are

	£
Secretary for Health (1)	3500
Directors of medical services (3)	3050
Deputy directors of medical services (3)	2850
Directors public health laboratories (4)	2750
Ophthalmologists (3)	2750
Medical superintendents (9)	2750
Senior medical officers (9)	2750
Radiologists (3)	2750
Specialists (surgery medicine psychiatry, anaesthesia tuberculosis leprology) (19)	2750
Provincial medical officers of health (4)	2750
Medical superintendents (3)	2450
Radiologists (4)	2450
Pathologists (3)	2350
Medical superintendents (5)	2350
Medical superintendents (3)	2250
Medical superintendents (2)	1925–2050
Medical officers of health (8)	1775–2050
Government medical officers (144)	1350–2050
Schools medical officers (2)	1350–2050

Government medical officers are permitted private general practice in the rural areas, the value of this varies considerably and may reach £1000 a year, but where the net receipts fall below £200 a year a payment is made to bring the total receipts to that figure In other areas no private practice is allowed and an allowance of £200 a year is paid in lieu Medical officers of health who have not been promoted before reaching the top of their scale are paid a non-pensionable allowance at the rate of £50 a year for each year they remain at the top of their scale up to a maximum of £200 per annum Medical superintendents and most specialist officers are allowed consultant practice, the cash value of which is not great The duties of Government medical officers include the supervision of general and special hospitals and African clinics and dispensaries, medicolegal work, and preventive medicine They also include attendance on those officers of the Federal and Territorial Governments and others who are entitled to free medical attention, such as boarders in Government schools and prisoners These duties thus provide a wide field for clinical work and for the investigation and treatment of African diseases Generous provision is made in the regulations for the grant of study leave with pay to officers who wish to attend approved postgraduate courses in order to obtain additional qualifications

Vacancies are normally advertised, but where possible the more senior posts are filled by promotion within the service Further details may be obtained from the Secretary to the High Commissioner for Rhodesia and Nyasaland, 429, Strand, London, W C 2

MEDICAL MISSIONARY SERVICE

CHRISTIAN medical men and women who wish to offer their services where the need is greatest will find opportunities in medical missionary work There are university medical schools, central and rural hospitals, and many opportunities for public-health work and research Christian missions in India and Pakistan have helped to maintain high ethical and professional standards, and have specialised in nursing and medical education In Africa they have pioneered rural health services and the training of nurses, midwives, and subordinate staff In many parts of the world the work is becoming integrated with the government services though still maintaining its identity For undergraduates pledged to this service there are hostels in London and Edinburgh After qualification, a period of eighteen months or two years in resident appointments is advised for all and also special diplomas or higher degrees for some Under certain circumstances exemption is given from National Service Special missionary training is required by some societies Service is for terms from eighteen months to five years, according to the country and climate, there are opportunities for postgraduate study during furloughs Offers for life service are preferred, but short terms are considered Financial rewards are not high but vary with need Passages are free and quarters provided For long-term service many societies have pension provision Help is given with children's educational costs Applications from students or qualified men and women should be made either to the secretary of one of the denominational or interdenominational missionary societies, or through the local branch of the Student Christian Movement or the Inter-Varsity Fellowship, or to the Chairman, Medical Advisory Board of the Conference of British Missionary Societies, Edinburgh House, 2, Eaton Gate, London, S W 1

Other Information

THE MEDICAL RESEARCH COUNCIL

THE Medical Research Council, originally established in 1913 as the Medical Research Committee, is appointed to administer the funds provided annually by Parliament for the promotion of research in medical science The council is under the general direction of a committee of Privy Council, consisting of the Lord President as chairman and the Ministers in charge of the principal departments concerned with questions of public health at home and overseas The Lord President is the Minister responsible to Parliament for the council's work The members of the council, appointed by the committee of Privy Council normally for a period of four years, are twelve in number Nine of these are chosen for their scientific qualifications, of the remaining three, one must be a member of the House of Lords and one a member of the House of Commons

Although its funds are largely provided out of the Parliamentary grant-in-aid, the council is not a Government department and its staff are not Civil Servants, its constitution gives it full liberty to pursue an independent policy, and enables it to foster effective relations between science and the State, unrestricted by territorial or departmental limitations of function The council maintains close touch with the Government departments having responsibilities for public health, collaborates freely with its sister research organisations, the Department of Scientific and Industrial Research and the Agricultural Research Council, and has direct relations with similar organisations abroad

The council supports research in two main ways by employing its own scientific staff and by a scheme of grants and training awards which it makes available to workers elsewhere for specific purposes The council's annual report, published by H M Stationery Office, gives an account of the work in progress under its auspices

The council's scientific staff, with technical and other assistants, work in one major institute—the National Institute for Medical Research, Mill Hill, London, N W 7—and in some seventy research units or groups of varying size, or in some cases as individually attached workers, in universities and hospitals mainly in the United Kingdom but also in certain colonial territories The council also provides the major portion of the finance of the Institute of Cancer Research in the Royal Marsden Hospital, London, S W 3

The work of the National Institute for Medical Research, which is the largest of its kind in the Commonwealth, is designed to cover as wide a field as possible in basic non-clinical medical research, it has separate divisions of biochemistry, organic chemistry, chemotherapy, bacterial physiology, physiology and pharmacology, human physiology, immunology, experimental biology, bacteriology and virus research, biophysics and optics, biological standards, and engineering The council's research units and groups are housed, by mutual agreement, mainly within university or hospital departments

The close association of most of the council's establishments with universities and hospitals is valuable from many points of view, and especially in the opportunities it provides not only for collaboration in joint schemes of research but also for informal day-to-day discussions on scientific problems of common interest Members of units and of the external staff accommodated in university departments are often given honorary university appointments and participate to a limited extent in teaching, while in appropriate cases members of clinical units hold honorary hospital appointments In accordance with the recommendations, in the *Report on Clinical Research in Relation to the National Health Service*,[1] arrangements have been made by the council, in consultation with the Health Departments and with the advice of the Clinical Research Board, for the further development of research in this field

The interests of the council and of the universities are necessarily closely aligned in the research field but they do not merely duplicate each other The work of the council is complementary to that of the universities and under the terms of its constitution it is particularly well placed to explore new fields as they come to light and to develop new subjects rapidly on a large scale

The council's aim is to provide the opportunity for careers equivalent to those offered in the universities to men and women of equal ability and experience Its salary scales are based on this principle and approximate closely to the various grades of university appointments, the director of a council unit normally being considered to be of professorial status For the most part salaries are not fixed in relation to particular posts, but rather with reference to the ability and responsibilities of the individual promotion to a higher grade may accordingly be made without change of post The council's staff number about 2100, of whom some 700 are scientific staff and about one-half of these medically qualified.

---

[1] H.M Stationery Office, 1953

Appointments to the scientific staff are made on the recommendations of the director of the establishment concerned, normally for three or five years in the first instance. Later, when an adequate degree of seniority has been attained, the council may express its intention of continuing employment until the normal retiring age of 60, with the possibility of extension to 65. Superannuation provision is made for most appointments.

PUBLIC HEALTH LABORATORY SERVICE

On behalf of the Ministry of Health, the council have administered the Public Health Laboratory Service since 1939 when it was originally set up as an emergency service. There are over 60 separate laboratories in England and Wales. In addition to their routine duties, members of the staff of the service, whose salary scales are normally equated with those of the National Health Service, undertake research in bacteriology and epidemiology. The service also maintains a number of special laboratories which act as reference centres for particular infections, and are engaged largely in research.

The following booklets covering various aspects of the council's activities are available on request to the Secretary, Medical Research Council, 38, Old Queen Street, Westminster, London, S.W.1: Constitution and Functions, Careers in Medical Research, Research Grants.

MEDICAL PRACTICES ADVISORY BUREAU

WHEN the National Health Service Act came into force, the traditional procedure for entry into general practice was considerably modified—particularly by the abolition of the sale and purchase of goodwill. It soon became apparent that there would be a need for some central source of information which could give advice to practitioners seeking openings, to those desiring to transfer from one area to another, and to those seeking to set up in single-handed practice. It was felt that advisory functions of this kind should be undertaken by a body which was not linked directly or indirectly with central or local government but whose status and resources were such as would enable it to establish and maintain effective liaison with executive councils, local medical committees, and the Medical Practices Committee, and at the same time to command the confidence of the profession. To meet this need the Medical Practices Advisory Bureau was established at the end of 1948 as a department of the British Medical Association, under the direction of a member of the medical staff of the association.

The functions of the bureau are twofold: firstly, to maintain an information service about openings in the various fields of medical practice and to introduce partners, assistants, and locums; and, secondly, to advise on individual and personal problems associated with entry into and the conduct of medical practice. A great deal of advice is sought on the various forms of contracts and agreements between practitioners. Although it is not the function of the bureau to give legal advice there are many questions concerning partnerships and assistantships where the advice of a doctor with experience is needed, as well as that of a lawyer. All doctors are welcome to seek the advice of the Bureau, at B.M.A. House, Tavistock Square, London, W.C.1, or any of its branch offices. Those who are not members of the B.M.A. are required to pay nominal charges for the agency services.

THE BRITISH MEDICAL STUDENTS' ASSOCIATION

THIS association was founded in 1942 and its membership now includes over 90% of the medical students in the country. It is purely a professional organisation providing a means of communication between medical students in the different universities and hospitals and also between British students and those in other countries. It presents the medical students' viewpoint to the medical profession, to Government departments, and to other interested bodies. The organisation of the association is based on an annual general meeting at which an executive committee is elected, and on four regional councils. From time to time the association arranges clinical and preclinical conferences and "schools" which are appreciated not only for their academic interest but also for the opportunities which they provide for meeting fellow students from other medical schools. Local activities include lectures, visits, discussions, and the showing of films from the B.M.A. and other film libraries. Amongst its publications are the *British Medical Students' Journal*, which appears once a term, the B.M.S.A. Diary and an annual list of vacation appointments for those members requiring work in hospitals during vacations.

The B.M.S.A. is keenly interested in the grants problems of its members: cases of hardship are investigated and if necessary taken up with the appropriate authorities. In order to further this service a representative of the association sits as an observer on the National Union of Students grants and welfare committee.

The association has recently taken an active interest in the formation of the B.M.A.'s newly organised Junior Members Forum and its representatives attend the forum meetings. B.M.S.A. is represented on the other committees of the B.M.A. which discuss matters of interest to medical students and newly qualified doctors and on the undergraduate education committee of the College of General Practitioners. It also has liaison with the council of the College of General Practitioners. It maintains its close interest in the British Student Tuberculosis Foundation, of which it is a sponsoring body, and is a founder member of the United Kingdom committee of the World Health Organisation.

The association is a founder member of the International Federation of Medical Student Associations (I.F.M.S.A.), whose membership now embraces the associations of 21 nations, and the I.F.M.S.A. continues to develop successfully and is recognised by the World Medical Association and Unesco. Under the auspices of I.F.M.S.A. the annual Students' International Clinical Conference will be held this year in Scandinavia. This conference is one of the many opportunities available to members of the association, enabling them to travel and see something of medicine in other countries as well as meeting future doctors of many nationalities. Excellent arrangements also exist for foreign students to visit hospitals in this country and this year has seen an enormous increase in the number of students, both British and foreign, making use of these facilities. To encourage and assist deserving British students to attend courses and hospitals abroad the B.M.S.A. established four years ago a student travel fund. This year the administrators of the Fund awarded 24 scholarships to the total value of £200. It is hoped to improve further on this figure in future years. The B.M.S.A. is greatly indebted to the generous donors without whose gifts the international activities of the association would not be possible.

The principal interest of the association has continued to be the problem of the medical curriculum. Over the past two years the medical education subcommittee has prepared reports on entry to the medical course, the first year of medicine, and the preclinical curriculum. This year a detail survey of the clinical curriculum has been carried out, and it is hoped that the subcommittee's report will be available by the end of the year. This work has excited considerable interest amongst the profession and our views have been well received by a large number of medical educationalists. The subcommittee would be pleased to send reports to those interested and happy to receive comments on them.

The B.M.S.A. is fortunate to have a past president of the B.M.A., Sir Tudor Thomas, as its honorary president this year. The annual general meeting this year will be held in London on Nov. 12-14 and it is hoped that all member schools will send full delegations. Observers from the non-member schools will be very welcome.

The address of the association is B.M.A. House, Tavistock Square, London, W.C.1.

COMMONWEALTH MEDICAL ADVISORY BUREAU

THE British Medical Association set up the Commonwealth Medical Advisory Bureau with a view to making the stay of overseas medical visitors to this country as profitable and pleasant as possible, by welcoming them and providing a personal advisory service. The bureau, which is at B.M.A. House, Tavistock Square, London, W.C.1, caters for doctors from overseas parts of the Commonwealth who are staying in this country for postgraduate education or other purposes. Information is obtainable about postgraduate education and courses of study for higher qualifications, and inquirers can be put in touch with the organisations and authorities providing postgraduate education. The visitor who wishes to see something of the latest medical work in his own specialty can be put in touch with the appropriate experts.

A register of suitable hotels and lodgings is maintained by the bureau, and every effort is made to help visitors to solve the problem of finding somewhere to live. By social functions, and in other ways, overseas doctors are enabled to meet each other and prominent members of the profession in this country. General information about travel, sports facilities, exhibitions, theatres, &c., can also be given. The bureau can be of greatest service to the visitor if he writes as long as possible in advance of arrival, giving information on the following lines: projected date of arrival, mode of travel, whether accompanied by wife and children, period of stay, objects of the visit, and in what ways assistance is desired. If he wishes to visit hospitals or obtain advice on courses of study it is advisable for him to supply information about his own professional experience. On arrival a letter of introduction from the local hon. secretary of the visitors' medical association, although not essential, would be welcome. The medical director of the bureau is Dr. R. A. Pallister, to whom all communications should be addressed.

INTERNATIONAL MEDICAL ADVISORY BUREAU

THE British Medical Association has set up the International Medical Advisory Bureau to provide a personal advisory service to doctors visiting the United Kingdom from countries outside the British Commonwealth. The bureau, which is at B.M.A. House, Tavistock Square, London, W.C.1, offers information on postgraduate education facilities, visits to hospitals and clinics can be arranged, and help given in finding accommodation. General information on travel, car hire, theatres, and exhibitions is also available. The medical director is Dr. R. A. Pallister, to whom all communications should be addressed.

THE MEDICAL WOMEN'S FEDERATION

ALL medical women on the British Medical Register are eligible as members of the Medical Women's Federation, which has active local associations all over the country and in Northern Ireland, as well as a large London association and an overseas association linking up members all over the world. The federation is non-political. It provides medical and social meetings for its members and publishes a quarterly journal reviewing subjects of special interest to women doctors. These naturally cover a wide tract of social medicine, including maternity and child welfare, women in industry, the care of children and of difficult and delinquent children, the management of nursery schools and day-nurseries, women in prisons, children in approved schools and remand homes, the illegitimate child, and many related subjects. Advances in obstetrics and gynæcology, and psychological studies of women and children, are naturally of special interest to women doctors; recent work in these branches of medicine is reviewed in the journal. From time to time the federation undertakes social studies and publishes the results. It is also able to protect the interests of its members by presenting arguments in any cases where there has been discrimination against women doctors. The federation's headquarters are at Tavistock House North, Tavistock Square, London, W.C.1.

Notes and News

RES MEDICA

ONE of the newest medical journals comes from the oldest medical society in this country—the Royal Medical Society, formed at Edinburgh in 1737, only a few years after the medical faculty was founded in the university. Among royal societies this one is unique in that it is now run wholly by undergraduates, though its membership is not confined to students (or even to doctors), and it is unusual again in that it is not a university society, though it depends on the medical faculty for nearly all its members. Many men since famous have been its president—among them Sir Robert Hutchison, senior president in 1893, who contributed a foreword to the society's bicentenary history a few years ago.[1]

The society's new journal is called *Res Medica*.[2] Its contents will be derived mainly from the dissertations delivered by the student members on those Friday evenings in autumn and spring which "remain as always the society's highlight."

TWO OR THREE YEARS IN AUSTRALIA?

FOR at least a decade, people have been saying that there ought to be more exchange of young doctors between Commonwealth countries, and at one time, for example, there were hopes that hospitals in Britain and Australia would arrange to exchange residents for suitable periods. The scheme described by the State of Victoria in our advertisement columns this week is not an exchange scheme—though it originates perhaps from the fact that so many Australian graduates come to work for a time in this country. In proposing favourable terms on which men and women qualifying here can spend two or three years as residents in Australian country hospitals (ranging in size from about 100 to about 300 beds) the Government of Victoria are hoping, presumably, that a proportion will want to stay in their State, where the increase in the medical profession does not keep pace with the increase of population. For those who contemplate settling in Australia the scheme certainly offers an ideal introduction, but, even for those who fully intend to return, an Australian residency could be an unusually instructive and enlarging experience.

THE PROPHYLAXIS OF IRON-DEFICIENCY ANÆMIA IN PREGNANCY

DAVID N S KERR
M B Edin , M S Wisconsin, M R.C P E , M.R.C P.
ASSISTANT, DEPARTMENT OF MEDICINE, UNIVERSITY OF EDINBURGH

SIR STANLEY DAVIDSON
B A Cantab , M D Edin , F R.C P E , F R C P
PROFESSOR OF MEDICINE, UNIVERSITY OF EDINBURGH

IN the hundred and twenty years since Nasse wrote his original monograph on anæmia in pregnancy, a voluminous literature has appeared Some of the century-old controversies about the cause of this anæmia have been resolved with the advent of methods for measuring directly the plasma volume and red-cell mass It is now agreed that there are three main factors

(1) An increase in plasma volume that outstrips the simultaneous increase in red-cell mass (Dieckmann and Wegner 1934, Thomson et al 1938, Roscoe and Donaldson 1946, McLennan and Thouin 1948, Tysoe and Lowenstein 1950, Lund 1951, Berlin et al 1953)

(2) A deficiency of iron due to the demands of the fœtus (Rath et al 1950, Moore 1955, *Lancet* 1955)

(3) A deficiency of folic acid and possibly of cyanocobalamin due to the increased demands of the fœtus and of the pregnant woman and to impaired absorption during pregnancy

The megaloblastic anæmia of pregnancy accounts for only a very small proportion of cases of anæmia during pregnancy

The anæmias of pregnancy not due to folic-acid or cyanocobalamin deficiency have been divided by many authors into two groups—"hypochromic" and the so-called "physiological", the former being indistinguishable from iron-deficiency anæmia in non-pregnant women The "physiological" anæmia differs in certain important respects from iron-deficiency anæmia in non-pregnant women, as shown in table I, which was constructed after studying the published work of Dieckmann and Wegner (1934), Goodall and Gottlieb (1936), Fay et al (1949), Rath et al (1950), Hahn et al (1951), Caton et al (1951), Berlin et al (1953), and Verel et al (1956) Because of these dissimilarities, it has been argued that the "physiological" anæmia cannot be due to iron deficiency This view has been supported on the grounds that the red-cell mass often increases during pregnancy and returns to normal in the puerperium (Caton et al 1949, 1951, Berlin et al 1953) The argument, however, that has swayed medical opinion most cogently against the idea of a "physiological" anæmia of pregnancy has been the fact that it can usually be corrected with iron (Scott and Govan 1949, Klopper and Ventura 1951, Benstead and Theobald 1952, Davis and Jennison 1954, Lillie et al 1954, Fisher and Biggs 1955, Edgar and Rice 1956), which often causes a rise in mean corpuscular hæmoglobin concentration (M C H C) even when the latter was in the normal range before treatment The view that an anæmia which responds to iron in the same manner as a mild iron-deficiency anæmia cannot be physiological has recently gained wide acceptance, and many authorities now recommend that all women should receive iron supplements during pregnancy (*Lancet* 1955, 1956)

At the same time it should be noted that some workers (Fisher and Biggs 1955, Edgar and Rice 1956) have found that 10–20% of patients are anæmic in late pregnancy even when adequate doses of iron have been prescribed Several possible explanations have been suggested (1) failure to take the prescribed iron, (2) failure to absorb iron, (3) mild folic-acid deficiency, (4) an unusually large increase in plasma volume Since the last is probably the most important factor, a simple, safe and satisfactory procedure for the measurement of red-cell mass which did not involve the use of radioactive isotopes would be very helpful in determining the nature of these refractory cases

The incidence of anæmia varies considerably in different populations, according to the economic conditions (Strauss and Castle 1932, Davidson et al 1935, Fullerton 1936, Doyle and McGrath 1954), and considerable social changes have taken place in Edinburgh since the last survey (Roscoe and Donaldson 1946) To help formulate a practical policy for the prophylaxis of iron-deficiency anæmia in pregnancy we have therefore undertaken a study on patients attending the Simpson Memorial Maternity Pavilion, Edinburgh, to ascertain

(1) The incidence of anæmia in pregnancy

(2) The effect of season, age, parity, recent pregnancy, and duration of pregnancy on the incidence and degree of anæmia

(3) The adequacy of the present diet of Edinburgh mothers

(4) The most suitable forms of oral iron to administer, if supplements are necessary, in regard to their efficiency, economy, and lack of undesirable side-effects

(5) The stage in pregnancy at which iron supplements should be started

(6) Whether the addition of ascorbic acid to ferrous gluconate pills confers any advantage upon them

The effect of adding ascorbic acid to the iron pills was investigated because (*a*) ascorbic acid aids the absorption of iron (Powell 1944, Moore 1955), (*b*) a deficiency of ascorbic acid increases the incidence of anæmia in pregnancy, and the administration of ascorbic acid corrects the anæmia, though less effectively than iron (Scott and Govan 1949), and (*c*) tablets containing ascorbic acid as well as iron are stated to be better tolerated than iron alone (Fisher and Biggs 1955)

Investigation of Incidence of Anæmia

To obtain information in regard to problems 1 and 2 a study was made of the case-notes of all the patients attending the antenatal clinic of the Simpson Memorial Maternity Pavilion, in the periods February–March and August–September of 1955 and 1956 After excluding patients who were found to have any disease likely to

TABLE I—COMPARISON OF IRON-DEFICIENCY ANÆMIA WITH "PHYSIOLOGICAL" ANÆMIA OF PREGNANCY

—	Iron-deficiency anæmia	"Physiological" anæmia of pregnancy
Colour index	Low	Normal
M C.H C.	Low	Low normal
M C V	Low	High normal
Reticulocyte count	Low	Raised
Serum iron	Low	Normal or low
Iron-binding capacity (I.B C.)	High	High
Ratio of serum iron to I B.C.	Very low	Low
Iron absorption	Increased	Increased
Free erythrocyte protoporphyrin	Increased	Slightly increased
Serum copper	High	High
Total red cell mass	Low	Normal or increased
Total body hæmoglobin	Low	Normal or increased
Plasma volume	Increased +	Increased +++
Response to iron therapy	Rise in Hb +++	Rise in Hb +

cause anæmia or who were receiving iron at the time of their first visit, the number of case-notes available for analysis was 1994—an average of about 500 patients for each of the four periods Hæmoglobin levels were estimated routinely at the first visit by the oxyhæmoglobin method, in an EEL photoelectric colorimeter, using capillary blood obtained by pricking the finger

Of these 1994 patients, 1071 attended the clinic for the first time before the twelfth week of pregnancy (table II) Of this number *631* required and received iron medication, the remaining 440 patients were given no iron Table VII summarises the changes in hæmoglobin level in these 440 women between the first visit and the 23rd to 27th week of pregnancy

Tables II–VI show the incidence of anæmia in the 1994 patients in relation to the stage of pregnancy at their first visit, the season when they were first seen at the clinic, their age, their parity, and the number of their pregnancies within the previous five years

FINDINGS

Incidence of anæmia (table II)—The mean hæmoglobin level of 1071 women seen initially in the first 11 weeks of pregnancy, a period during which the occurrence of hydræmia is insignificant, was 12 9 g per 100 ml (88%) (Hæmoglobin percentages given are based on the scale that 14 8 g per 100 ml = 100%) A hæmoglobin level below 10 4 g (70%) was found in 2% of the women, while 32% had a level below 12 6 g (85%)

TABLE II—HÆMOGLOBIN LEVEL AT FIRST ANTENATAL VISIT IN 1955–56

Week in pregnancy when Hb level was estimated	No of patients	Mean hæmoglobin level		Standard deviation	
		g per 100 ml	%	g per 100 ml	%
1–40	1994	12 6	85	1 30	8 8
1–11	1071	13 0	88	1 39	9 4
12–23	698	12 4	84	1 31	8 9
24–40	225	11 6	78	1 32	8 9

The mean hæmoglobin level was lower in women first seen at a later stage in pregnancy, the difference being highly significant ($P<0\ 001$) Of the 225 women first seen at the 24th week or later, 13 7% had a hæmoglobin level of less than 10 4 g per 100 ml (70%) and 78 1% had a hæmoglobin level of less than 12 6 g per 100 ml (85%)

Seasonal variation (table III)—Women first seen at the end of the winter (i e, in February and March) had higher hæmoglobin levels on the average than those first seen at the end of the summer (i e, in August and September) The difference between these two groups is highly significant ($P<0\ 001$)

Effect of age (table IV)—To assess the effect of age on the incidence of anæmia, without the complicating factors of previous pregnancies and iron therapy, the case-records of 300 primigravidæ seen in 1955 who were not receiving iron therapy at the time of examination were analysed No significant difference was found between the mean initial hæmoglobin levels of women under and over 25 years of age Subdivision into narrower age-groups again showed no significant difference Age has therefore been ignored in assessing the effect of parity

Effect of parity (table V)—The mean hæmoglobin levels of 618 primigravidæ and 390 parous women were compared at different stages of pregnancy No significant difference was found ($P>0\ 3$)

TABLE III—SEASONAL VARIATION IN THE INCIDENCE OF ANÆMIA I PREGNANCY COMPARISON BETWEEN WOMEN WHO FIRST ATTENDED TH ANTENATAL CLINIC AT THE END OF THE SUMMER (AUGUST–SEPTEMB AND AT THE END OF WINTER (FEBRUARY–MARCH) 1955 AND 1956

Stage in pregnancy when Hb level was estimated (weeks)	Season	No of patients	Mean hæmoglobin level		Standard deviation	
			g per 100 ml	%	g per 100 ml	%
0–11	Summer	534	12 5	84	1 11	75
	Winter	537	13 5	91	1 26	85
12–23	Summer	358	12·0	81	1 11	7·5
	Winter	340	12 8	87	1 36	92
24–40	Summer	99	11 1	75	1 23	83
	Winter	126	11 8	80	1 30	88

Effect of recent pregnancies (table VI)—The me hæmoglobin levels of women who had borne no childre one child, or two *or more* children *within the five ye* period preceding the present pregnancy were compare There was no significant difference between the groups

Fall in hæmoglobin level during second trimester—The mean fall in hæmoglobin level between the fir estimation (during first 11 weeks of pregnancy) an second estimation (23rd–27th week of pregnancy) in th 440 women who were known to have received no iron *shown in table* VII, *where it is compared with the* init hæmoglobin level The fall was greatest in those wome with an initially high hæmoglobin level, even when was expressed as a percentage of the original lev The difference in the mean fall in hæmoglobin level patients with an initial hæmoglobin level of 12 6 g p 100 ml (85%) or more was significantly greater ($P<0\ 0$ than in those patients with an initial hæmoglobin lev *below 12 6 g*

Investigation of Iron Preparations

To obtain information about the potency and toxici of certain iron preparations an investigation was unde taken of all women attending the antenatal clinic of th Simpson Memorial Maternity Pavilion between Marc *1956*, and *June, 1957*, during their *24th* or 25th week pregnancy, provided that

(1) Their hæmoglobin level was 10 4 g per 100 ml o above

(2) They had no disease likely to cause anæmia or excessiv hydræmia

(3) They did not have twins

(4) They were not already receiving iron therapy

(5) They intended to continue attending the antenatal clin till term

The 430 women accepted for this investigation wer assigned by random selection (choosing a card from pack) to one of four groups Group A (20%) receive ferrous sulphate, group B (20%) received ferrou gluconate, group C (20%) received ferrous gluconat plus ascorbic acid, and group D (40%) formed th control group which received pills containing lactose

The pills prescribed were identical in shape, colour, an

TABLE IV—EFFECT OF AGE ON THE LEVEL OF HÆMOGLOBIN OF 3 PRIMIGRAVIDÆ

Stage in pregnancy when Hb level was estimated (weeks)	Age	No	Mean hæmoglobin level		Standard deviation	
			g per 100 ml	%	g per 100 ml	%
0–11	Under 25	97	12 9	87	0 83	5·6
	25 and over	90	12·9	87	1 03	7·0
12–23	Under 25	81	12 2	83	0·99	6 7
	25 and over	32	12·0	81	1·04	7·0

TABLE V—EFFECT OF PARITY ON THE HÆMOGLOBIN LEVEL OF 618 PRIMIGRAVIDÆ AND 390 PAROUS WOMEN

Stage in pregnancy when Hb level was estimated (weeks)		Season	No of patients	Mean hæmoglobin level		Standard deviation	
				g per 100 ml.	%	g per 100 ml	%
1–11	Prim.	Summer	184	12·3	83	1·02	6·9
	Parous.	Summer	81	12·3	83	1·05	7·1
	Prim.	Winter	181	13·0	88	1·20	8·1
	Parous	Winter	94	13·2	89	1·11	7·5
12–23	Prim	Summer	97	11·8	80	1·12	7·6
	Parous	Summer	71	11·9	81	1·07	7·2
	Prim	Winter	103	12·4	84	1·26	8·5
	Parous.	Winter	65	12·4	84	1·38	9·3
24–40	Prim.	Summer	21	11·2	76	1·27	8·6
	Parous	Summer	33	11·1	75	1·05	7·1
	Prim	Winter	32	11·5	78	1·26	8·5
	Parous	Winter	36	11·6	78	1·01	6·8

coating As the control group was larger than the others, it was necessary for the doctors conducting the trial to know which were the control pills, the other three preparations were known as pills A, B, and C, and their identity was not known to patients or doctors until the trial was finished and the results had been analysed.

Careful consideration was given to the dosage of iron to be incorporated in the pills It was essential that the daily iron intake should be the same irrespective of which preparation was being taken. The dose of ferrous gluconate usually recommended is one 300 mg (gr 5) pill containing 35 mg of elemental iron, given three times a day, making a total of 105 mg of iron daily Ferrous sulphate, however, is usually prescribed as one 180 mg (gr 3) pill containing 60 mg of elemental iron, three times a day, making a total of 180 mg of iron daily We had to decide at the outset whether to increase the dose of elemental iron in each ferrous-gluconate pill to 60 mg—i e, approximately double the usual therapeutic dose—or to reduce the amount of elemental iron in each ferrous-sulphate tablet from 60 mg to 35 mg The latter choice was made because we wished to know not only about the therapeutic efficiency of ferrous gluconate and the incidence of side-effects when it was given in the usual dosage mentioned above, but also whether the addition of 25 mg of ascorbic acid to each ferrous-gluconate pill would increase its efficiency or reduce its toxicity Accordingly each ferrous-sulphate and ferrous-gluconate pill used in this investigation contained 35 mg of elemental iron.

Each patient was given both oral and written instructions which explained that she was going to be given a preparation of iron to prevent or cure the anæmia which tended to develop in pregnancy It was also emphasised that the pills were to be taken three times a day after food, and stress was placed on the need to take them regularly for the period prescribed No mention was made of control pills containing lactose The possibility that 40% of pills ingested did not contain iron was apparently not suspected by the patients, since only 2 commented on the fact that their motions were not black

Patients were recalled for the second interview at the 37th week, when each was asked to estimate her weekly intake of certain iron-containing foods (meat, liver, bacon, fish, eggs, soups, potatoes, cereals, bread, milk, beverages, chocolate) during the period of the trial From this her daily intake of iron was calculated, figures for the iron content of foods were taken from tables constructed by McCance and Widdowson (1946)

At this second interview patients were asked whether they had suffered any symptoms from taking the pills, and if so whether they interfered with the treatment. Symptoms were graded "mild" (no interference with treatment) "moderate" (temporary interruption of treatment) and "severe" (obliged to stop treatment) Only gastrointestinal symptoms were recorded as being due to the pills Patients were also asked whether they had taken the pills conscientiously Only 6 of the patients who did not complain of intolerance to iron admitted that they had taken the pills irregularly

37 women were unable to take the prescribed course of pills because of "severe" toxic effects In addition 61 failed to complete the trial because of premature delivery, conditions complicating pregnancy (e g, toxæmia), intercurrent illness, removal from the district, or unwillingness to cooperate

Hence of the original 430 patients, 332 took their pills regularly and came to the second interview A study has been made of the potency of the different oral iron preparations used in the treatment of this group of women The 61 women who failed to attend were sent a questionnaire in which they were asked to record any gastrointestinal symptoms experienced while taking the pills From these questionnaires and from the information given by the 369 women (332 + 37) attending the second interview, it was possible to analyse the incidence of toxic symptoms in a total of 410 patients

TABLE VI—EFFECT ON HÆMOGLOBIN LEVEL OF NUMBER OF PREGNANCIES WITHIN THE LAST FIVE YEARS (PATIENTS SEEN IN 1955)

Stage in pregnancy when Hb level was first estimated (weeks)	Season	Pregnancies within last five years	No in group	Mean hæmoglobin level		Standard deviation	
				g per 100 ml	%	g per 100 ml	%
0–11	Summer	0	202	12·8	87	1·08	7·3
		1	56	12·4	84	1·29	8·7
		2 or more	11	12·1	82	1·15	7·8
	Winter	0	173	13·8	93	1·21	8·2
		1	75	14·1	96	1·29	8·7
		2 or more	15	14·4	97	1·45	9·8
12–23	Summer	0	120	12·1	82	1·10	7·4
		1	48	12·2	82	1·18	8·0
		2 or more	23	12·0	81	1·11	7·5

		1	42	13·3	90	1·55	10·5
		2 or more	24	12·8	87	1·27	8·6

Venous blood was taken, with minimum stasis, at the 24–25th week and at the 37th week, and the hæmoglobin level (Hb), red-cell count (R.B C), and packed-cell volume (P C.V) measured

Hæmoglobin was estimated by the alkaline hæmatin method, using an E E L photoelectric colorimeter, red-cell counts were performed in duplicate in Neubauer counting-chambers, packed-cell volumes were measured after centrifugation for thirty minutes at 3000 r p.m in a standard hæmatocrit centrifuge. Between the two blood-tests the patients were not

TABLE VII—FALL IN HÆMOGLOBIN LEVEL DURING SECOND TRIMESTER IN 440 PATIENTS NOT RECEIVING IRON THERAPY

Initial hæmoglobin range		No of patients	Mean fall in hæmoglobin level		Standard deviation		Mean fall in hæmoglobin level as % of initial hæmoglobin level
g per 100 ml.	%		g per 100 ml.	%	g per 100 ml	%

normally seen by the investigators, but were supervised by the obstetricians. This supervision included further routine hæmoglobin estimations—usually two. Any patient whose hæmoglobin fell below 10·4 g. per 100 ml. (70%) was referred to the investigators. 11 patients taking control tablets were seen on this account; they were excluded from the trial and given iron pills. All responded normally. 4 who were taking iron pills were referred for the same reason. Additional counts were carried out. 1 patient was found to have megaloblastic anæmia of pregnancy; the remaining 3 were left on the same treatment, and eventually responded with a rise in hæmoglobin level.

FINDINGS

Dietary survey.—The replies by 95 successive patients taking control pills, who answered a more detailed dietary questionnaire, were analysed. The mean dietary intake of iron was estimated at about 11 mg. This was not the total intake, for only the major iron-containing foods were included in the questionnaire, but it was thought to represent 80–90% of the intake for the average woman. This gave an estimated mean iron consumption of approximately 13 mg. daily—an intake slightly below the minimum level of 15 mg. recommended for pregnant women by the B.M.A. Sub-Committee on Nutrition in 1950.

Effect of diet on hæmoglobin level.—The fall in hæmoglobin level in the 95 women in the control group during the last trimester of pregnancy has been compared with their estimated dietary intake of iron. The mean fall in 26 patients whose diet was unsatisfactory as regards iron (i.e., reckoned to contain less than 10 mg. daily) was 0·6 g. per 100 ml. (4%), whereas the mean fall in 69 patients whose dietary intake of iron was reckoned to be more than 10 mg. (16 of whom ingested more than 14 mg. daily) was 0·4 g. per 100 ml. (2·7%). It is obvious therefore that factors other than the total content of iron in the diet were important in determining the final hæmoglobin level. It is of interest that some women reckoned to be taking more than the recommended intake of 15 mg. of iron a day were found to have a considerable fall in hæmoglobin level.

Comparison of the iron preparations.—The changes in hæmoglobin level, red-cell count, and packed-cell volume in the four treatment groups are shown in table VIII. Hæmoglobin levels and packed-cell volume rose in each of the iron-treated groups and fell in the control group, the difference being significant (P<0·01). The red-cell count rose slightly in the control group, but the rise in each treatment group was significantly greater (P<0·05). These differences between the control and treatment groups would have been larger had not 11 patients who were originally assigned to the control group been excluded from the trial because their hæmoglobin level fell below 10·4 g. per 100 ml. (70%).

No significant difference between the changes in hæmoglobin level, red-cell count, and packed-cell volume was observed in the two groups treated with ferrous gluconate, with and without ascorbic acid (P>0·3). We conclude, therefore, that the addition of ascorbic acid does not affect the therapeutic value of ferrous gluconate, either beneficially or adversely. Accordingly the two groups treated with ferrous gluconate have been amalgamated and compared with the group treated with ferrous sulphate. The rise in hæmoglobin level, red-cell count, and packed-cell volume in the ferrous-sulphate group is less than in the groups receiving ferrous gluconate; the difference is significant (0·01<P<0·05) for the red-cell count, barely significant (P = 0·05) for the hæmoglobin level, and not significant (P<0·05) for the packed-cell volume.

The incidence of gastrointestinal intolerance to the pills is shown in table IX. There is no significant difference

TABLE IX—INCIDENCE OF GASTROINTESTINAL INTOLERANCE TO ORAL IRON PREPARATIONS

between the control pills and the iron pills, or between the three iron preparations. This suggests that most of the symptoms attributed by the patients to iron medication were either incidental or psychogenic in origin. It was thought possible that the gastrointestinal symptoms (morning sickness, heartburn, constipation) which are liable to occur in pregnancy might be obscuring the incidence of symptoms due to iron intolerance. An investigation of the side-effects of oral iron medication was therefore carried out on 93 normal women who were not pregnant. The results (Kerr and Davidson 1958) are very similar to those in the pregnant women and clearly demonstrate the great *importance of the psychological factor*.

Discussion

Although severe anæmia is now uncommon in pregnant women in Edinburgh, the incidence of mild anæmia at the beginning of pregnancy is still sufficient to justify wide-scale prophylaxis with oral iron therapy. Like many other authors, we noted a fall in the hæmoglobin level in the later stages of pregnancy.

The seasonal variation in the incidence is interesting.

Our findings that the incidence is highest at the end of summer contrasts with the finding of some other workers (Scott and Govan 1949, Lund and Kimble 1943, Doyle and McGrath 1954, Gatenby and Lillie 1955) who described a lower incidence in summer. We must frankly admit that we know of no satisfactory explanation of the seasonal fluctuations in the hæmoglobin level. They might reflect changes in the diet, but in our survey these were so small that they could have had no effect on the amount of iron in the food. Although no information was collected regarding the intake of fruit and vegetables, there are several reasons which convince us that the seasonal changes in the incidence of anæmia shown in table III are unlikely to be due to seasonal variations in the intake of iron and ascorbic acid derived from these sources.

No increase in susceptibility to anæmia was found with increasing age; this contrasts with the finding of Roscoe and Donaldson (1946), but these workers compared all women regardless of parity, whereas we compared primigravidæ only. Anæmia did not increase significantly with the number of children, or with the number of pregnancies in the previous five years. This is in marked contrast to the experience of one of us (S. D.) twenty-five years ago in Aberdeen. The most likely causes of the change are (1) the great improvement in the social and economic status of the working classes, particularly in the past fifteen years, (2) the stress laid by teachers of medicine on the importance of menstruation and pregnancy in the ætiology of iron-deficiency anæmia, and (3) routine hæmoglobin estimations in antenatal clinics and maternity hospitals and the administration of iron to all patients who are found to need it.

The fall in hæmoglobin level during the second and third trimesters, noted by previous workers was found in women who were not given iron. It is of interest that the women with initially high hæmoglobin levels sustained the biggest fall in hæmoglobin during the second trimester, and this was true also, though in lesser degree, during the third trimester (table X). The explanation is uncertain: possibly iron is absorbed more avidly in early pregnancy by patients who are already anæmic. Whatever the cause, the observation is of some practical importance because it means that a normal hæmoglobin level at the beginning of pregnancy, or even at the 24th week, does not guarantee the patient against anæmia at term. From the data used in compiling tables VII and X we were able to calculate that a woman (in the population studied) with an initial hæmoglobin range of 12·5 to 15·0 g. per 100 ml. (84–101%) at the beginning of pregnancy stands roughly a 10% chance of reaching "term" with a hæmoglobin level of less than 10 g. per 100 ml. (68%) if she is given no iron during pregnancy.

Administration of 105 mg. of iron daily between the 24th and 37th weeks caused a mean rise in hæmoglobin level, red-cell count, and packed-cell volume. This is a relatively small dose of iron and the final mean hæmoglobin level achieved—13·0 g. per 100 ml. (88%)—is not as high as that recorded by some other workers who used larger doses of iron, or the same dose for longer periods (Benstead and Theobald 1952, Edgar and Rice 1956). However, it is to be expected that the hæmoglobin level will rise further between the 37th week and term, as it rises slightly at this stage in pregnancy even in untreated patients, we feel that a final mean hæmoglobin level of about 13·5 g. (91%) at term is reasonably satisfactory. There are several reasons for giving iron routinely in late rather than early pregnancy. Firstly it has been shown that iron is better absorbed at this stage (Hahn et al. 1951). Secondly there is a considerable saving of money and trouble to the patient by limiting iron therapy to the last trimester. Thirdly the fœtal demands for iron are at their maximum. And fourthly therapeutic results will generally be found to be satisfactory.

Like Fisher and Biggs (1955) and Edgar and Rice (1956), we found that a proportion of the patients treated with iron failed to show a rise in hæmoglobin level (24% of those on ferrous sulphate and 23% of those on ferrous gluconate).

As a result of our investigations we suggest the following scheme of supervision for antenatal patients:

(1) Routine hæmoglobin estimation at the first antenatal visit. This has been the practice for many years in the Simpson Memorial Maternity Pavilion.

(2) Iron therapy from the first visit for all patients with an initial hæmoglobin level of less than 12·6 g. per 100 ml. (85%).

(3) Routine administration of elemental iron in a dosage of at least 105 mg. daily to all patients from the 24th week to term. This dosage is provided by one 300 mg. (gr. 5) pill of *ferrous gluconate*, three times a day. The customary dose of ferrous sulphate is one 180 mg. (gr. 3) pill three times a day which provides a much greater amount of elemental iron, namely 180 mg. per day.

The choice of preparation for iron therapy remains controversial This study suggests that ferrous gluconate may be slightly more efficient than ferrous sulphate (when given in the same dosage in terms of elemental iron—namely, 105 mg daily) in raising the hæmoglobin level, but the difference is barely significant Lillie et al (1954) claim that ferrous gluconate is slightly superior to ferrous sulphate in restoring the hæmoglobin level of anæmic persons, even when the amount of iron in the dose of ferrous sulphate given was greater However, the level *of significance is not stated and their two groups of* patients were not selected at random or concurrently In contrast O'Sullivan et al (1955) in a very carefully controlled investigation into the treatment of iron-deficiency anæmia in non-pregnant patients could find no significant difference in therapeutic efficacy between ferrous gluconate, ferrous succinate, and ferrous sulphate, all three preparations being given in a daily dose of 210 mg of elemental iron It seems to us, therefore, only reasonable to believe that better results would be obtained from giving 180 mg of iron daily in the form of ferrous sulphate than from giving ferrous gluconate in a daily dose containing 105 mg of iron, in which case the choice of preparation will depend essentially on relative cost and the frequency and severity of undesirable side-effects

From our inquiries in Edinburgh we are satisfied that ferrous sulphate is the least expensive preparation of iron available (Davidson and Richmond 1958)

As already noted, we have not been able to demonstrate any difference in the incidence of gastrointestinal intolerance between women receiving ferrous sulphate and those receiving ferrous gluconate—105 mg of iron daily in each case In fact, the incidence was the same in those taking the control lactose pills We attach great importance to the psychological factor in iron intolerance, and our experience is that the great majority of persons, pregnant or non-pregnant, can take one gr 3 ferrous-sulphate tablet thrice daily without experiencing any significant side-effects, provided the tablet is always taken after meals and the patient is assured by her doctor that the pills will cause no discomfort

We have not demonstrated that the addition of ascorbic acid to ferrous gluconate increases its therapeutic efficiency or reduces its side-effects This conclusion does not necessarily apply to populations whose diet contains less ascorbic acid, but in Britain today the use of iron-plus-ascorbic-acid pills appears to be a needless expense

Summary

(1) The incidence of anæmia in pregnancy in Edinburgh in 1955 and 1956 has been estimated Although severe anæmia is rare at the beginning of pregnancy, mild anæmia ($Hb < 12 6$ g per 100 ml [85%]) is common

(2) No correlation has been found between the incidence of anæmia and age, parity, or the number of pregnancies within the previous five years Possible reasons for these findings are discussed

(3) An estimate of the average daily dietary intake of iron in pregnant women in Edinburgh suggests that it is slightly less than the 15 mg usually recommended The incidence or degree of anæmia was not found to correspond closely with the dietary intake of iron

(4) Oral administration of iron supplements during the third trimester corrects the anæmia of pregnancy in about 80% of cases, even when the initial mean corpuscular hæmoglobin content is normal This time of administration appears to be suitable for routine purposes

(5) As regards gastrointestinal side-effects, no difference was found between ferrous sulphate and ferrous gluconate, given in doses containing 105 mg of iron daily Neither preparation caused significantly more unpleasant gastro-intestinal symptoms than the other or than the control pills containing lactose

(6) The addition of ascorbic acid to ferrous-gluconate pills has not been shown to increase their therapeutic efficacy or to reduce their toxic effects

We wish to express our gratitude to Prof R J Kellar and D Douglas Miller for permission to carry out this study at their clinics, and for their encouragement and help, to Dr F J Scandrett of th clinical research laboratories of the Simpson Memorial Maternity Pavilion, Edinburgh, whose staff was responsible for the routine blood examinations analysed in our investigation of the incidence of anæmia, to Sister Mary Stirling, sister-in-charge of the antenatal clinic, and to Dr J Richmond, Dr A Doig, and Dr E J Watson-Williams, and to Mr R Samson, technician, of the staff of the University department of medicine, who assisted in the investigation of iron preparations We are also indebted to Messrs John Wyeth and Brother Limited for the iron preparations tested and fo financial assistance, and to Dr Gordon Fryers, medical director, for his advice and help

"The need for accuracy, orderliness and a strict observance of rules increases in proportion as clinical and surgical techniques become more complex, more scientific, more a matter of the co-ordinated and carefully timed activity of a medical and nursing team Moreover, many of the new therapeutic and diagnostic procedures are, not infrequently, a serious threat to the patient's life As the risk increases so does the need for accuracy and order Thus, the system of rules and regulations which governs the performance of duties and the hierarchical relationships between different medical and nursing groups tends to become more complex and rigid"—RICHARD M TITMUSS, *Essays on "The Welfare State"*, p 201 London, 1958

GASTROINTESTINAL INTOLERANCE TO ORAL IRON PREPARATIONS

DAVID N S KERR
M B Edin, M S Wisconsin, M.R.C.P E, M R.C P
ASSISTANT, DEPARTMENT OF MEDICINE, UNIVERSITY OF EDINBURGH

SIR STANLEY DAVIDSON
B.A. Cantab, M D Edin., F R.C.P.E, F.R.C.P
PROFESSOR OF MEDICINE, UNIVERSITY OF EDINBURGH

IT was the opinion of Thomas Sydenham that "iron may be given in the largest doses without inconvenience" His optimistic view has been shared in later generations by the originators of a large number of oral iron preparations which now compete for favour in the advertisement columns of the medical press There is, however, a widespread belief among patients that iron inevitably causes gastrointestinal disturbance, particularly constipation

To most patients ten years ago "iron" was synonymous with green ferrous-sulphate tablets This preparation's popularity with the medical profession was well deserved In correcting iron-deficiency anæmia it had been found at least as effective as any of the other available preparations (ferrous chloride, ferrous carbonate, iron and ammonium citrate, colloidal iron) and it had a considerable advantage in cost and convenience (Davidson and Fullerton 1938) During the past ten years a number of organic iron preparations have appeared on the market, and have been widely used It is therefore desirable to re-examine the question of which oral preparation of iron is the most suitable for the treatment of anæmia, in both pregnant and non-pregnant patients

O'Sullivan et al (1955) compared three of the most popular preparations—ferrous sulphate, ferrous gluconate, and ferrous succinate They gave the three compounds, in doses containing equal amounts of elemental iron (210 mg daily) to matched groups of patients, and found similar rises in hæmoglobin level Few other comparisons between iron compounds have been made with the same control of dosage and type of patient, but numerous papers attest the therapeutic effectiveness of most of the popular iron pills Ferrous sulphate (Benstead and Theobald 1952, Devoe and Moses 1954, Talaga 1955, Gatenby and Lillie 1955, O'Sullivan et al 1955), ferrous gluconate (Jasinski 1949, Haler 1952, Gatenby and Lillie 1955, O'Sullivan et al 1955), ferrous succinate (O'Sullivan et al 1955, Gillhespy 1955, Cope et al 1956, Storm Mathiesen and Petersen 1956), ferrous calcium citrate (Talaga 1955), and several other compounds (Davidson and Fullerton 1938) have been shown to be capable of correcting iron-deficiency anæmia In most of the papers cited, a rise in hæmoglobin level of more than 1% per day was obtained when the pills were taken conscientiously in the recommended dosage Since the published evidence does not show that any one of these compounds is more efficient than the others, the choice between them depends mainly on two factors—cost and incidence of side-effects

With regard to cost we are satisfied that ferrous sulphate is the least expensive preparation of iron available (Davidson and Richmond 1958) With regard to side-effects, experiments on animals have shown that in *very large* doses ferrous sulphate is appreciably more toxic than comparable amounts of iron and ammonium citrate, and two to five times as toxic as ferrous gluconate (Hoppe et al 1955, Brown and Gray 1955) Accidental poisoning with ferrous sulphate, usually in children, has sometimes been fatal (Reissman et al 1955) It does not appear, however, that the symptoms of which patients complain when taking therapeutic doses of iron are simply milder forms of those caused by acute poisoning, since the latter are partly due to excessive absorption of iron (Reissman and Coleman 1955). For instance, constipation is the most common complaint of patients taking iron, whereas diarrhœa is an almost constant feature of ferrous-sulphate poisoning

Published reports of the incidence and severity of gastrointestinal intolerance to therapeutic doses of iron vary greatly

This variation is seen particularly with ferrous sulphate, whether given alone or with traces of other metals (molybdenum, cobalt, copper) Thus various authors have reported intolerance-rates ranging from 0 to 60% Many of the reports are difficult to assess, because inadequate information on dosage, number and type of patient, and definition of intolerance is given Some of the papers in which adequate data have been recorded are summarised in table I If the cases given very large doses of ferrous sulphate (360 mg of iron daily) are excluded, the incidence of intolerance in 367 patients receiving an average of 220 mg of ferrous sulphate daily is 4%, a figure comparable to that shown in table I as occurring after the ingestion of 210 mg of ferrous gluconate daily

In this analysis we have not taken into account the report by Talaga (1955), because the intolerance-rate of 60% in his series of patients was conspicuously different from that reported in all other trials included in table I in which comparable doses of iron were given

Study of the reports also shows that the iron content of the preparations of ferrous sulphate was usually larger than that of the other compounds, that the pills employed varied widely in colour, size, and type of coating, that the series of patients were not always comparable, and that the definition of "side-effects" varied from mild symptoms to a degree of intolerance necessitating cessation of treatment

It may be assumed that the enthusiasm shown by a doctor recommending treatment, and the statements which he makes to patients about the likelihood of side-effects, will also vary These factors can be eliminated only by arranging a trial in which pills with identical coating and the same iron content are given to matched groups of patients on the "double blind" principle—neither the patient nor the doctor knowing which preparation is being employed until after the results have been assessed

During such a trial carried out on antenatal patients by Kerr and Davidson (1958) a comparison was made between ferrous sulphate, ferrous gluconate, and inert tablets The incidence of gastrointestinal symptoms attributed by the patients to their pills was similar in the three groups It was felt that pregnant women might be unsatisfactory subjects for a detailed study of this kind, because they often suffer from constipation and heartburn, and because they spend a considerable amount of time sitting in queues at antenatal clinics, discussing their symptoms Accordingly a second double-blind trial was planned, using as subjects healthy non-pregnant young women The results are reported here

Plan of the Experiment

The purpose of the trial was explained to the nursing staff of the Royal Infirmary, Edinburgh, and 100 volunteers requested Each volunteer was given six packets of pills and asked to take them, in the dosage prescribed on the packets, after meals, from Monday to Friday during six successive weeks No pills were taken on Saturdays and Sundays, and at the end of each week a questionnaire was completed giving details of any symptoms experienced during the preceding week

TABLE I—INCIDENCE OF GASTROINTESTINAL INTOLERANCE TO ORAL IRON PREPARATIONS REPORTED BY VARIOUS AUTHORS

Calcium citrate	150	Nil	"	48	0	Talaga 1955

Six symptoms were mentioned specifically on the form—nausea, vomiting, heartburn, abdominal discomfort, constipation, and diarrhœa—and a space was left to record "any other symptoms" The volunteers were asked to describe only symptoms which they believed were due to the pills, they were not asked to grade their severity but merely to say whether they were severe enough to prevent their taking the full course of treatment prescribed for that particular pill If they were obliged to stop taking one pill on account of symptoms, they were asked to continue with the others according to schedule They were told that the first five packets contained iron pills of various types, some of which would change the colour of the stools while others would not The sixth packet was marked "control pills" and it was explained that these were given to make sure that the coating used on the other pills was not itself a cause of symptoms

The five "iron pills" contained ferrous sulphate, ferrous gluconate, ferrous succinate, ferrous calcium citrate, and lactose The last is hereafter referred to as the "unknown" control pill The pills known to the patient as the "control" pills also contained lactose, and were identical in appearance and composition to the "unknown" control pills

Careful consideration was given to the dosage of iron to be incorporated in the pills

It was essential that the daily iron intake should be the same irrespective of which preparation was being taken The usual dose of ferrous gluconate is one 300 mg (gr 5) pill and of ferrous succinate one 150 mg (gr $2^1/_2$) pill, each containing 35 mg of elemental iron, given three times a day, making a total of 105 mg of iron daily The dose of ferrous calcium citrate recommended by the manufacturers is two 300 mg (gr 5) pills each containing 25 mg of elemental iron, given three times a day, making a total of 150 mg of iron per day Ferrous sulphate, however, is usually prescribed as one 180 mg (gr 3) pill containing 60 mg of elemental iron, three times a day, making a total of 180 mg of iron daily At the outset a decision had to be made as to whether it was desirable to increase the dose of elemental iron in each ferrous gluconate and succinate pill to 60 mg—i e, about double the usual therapeutic dose—or to reduce the amount of elemental iron in each ferrous sulphate tablet from 60 mg to 35 mg The latter choice was made because evidence had been obtained by Kerr and Davidson (1958) that ferrous sulphate was effective when given in the smaller dose

Each ferrous-sulphate, gluconate, and succinate pill contained 35 mg of iron, the dose of these and of the "known" and "unknown" control pills was one, three times a day Ferrous calcium citrate could not be prepared in pills of the same size, with an iron content of 35 mg, it was therefore made up in pills containing 17 5 mg of iron, identical in other respects to the control pills, and given in a dose of two tablets three times a day To this extent the ferrous calcium citrate pills were distinguishable from the others, but, with this exception, the comparison was carried out as a double blind experiment, the key being opened only after the results had been analysed. The pills were identical in size, shape, colour, and coating

The volunteers were assigned at random to five groups which took the pills in different orders

103 nurses volunteered 7 failed to complete it for reasons unconnected with the pills (intercurrent illness, night duty, holidays) 3 others dropped out because they experienced unpleasant symptoms One of these complained of abdominal pain and diarrhœa, and another of constipation, while taking ferrous sulphate The third volunteer had various symptoms while taking ferrous calcium citrate, ferrous gluconate, and "unknown" control pills

The 93 volunteers who completed the trial were all healthy young women aged 18–30 years (mean age 21) The hæmoglobin level was not estimated routinely, but 23 volunteers when visiting the blood clinic to collect their pills asked that this estimation should be carried out Their hæmoglobin levels ranged from 11 7 to 15 5 g per 100 ml (79–105%), the mean being 13 9 g (94%) This suggests that most of the subjects were not significantly anæmic 11 had been treated with oral iron in the past, but none could recollect any untoward symptoms from this

Results

The replies given by the 93 who completed the trial are summarised in table II

In total incidence, "toxic effects" from the "unknown" control pills did not differ significantly from those accompanying any of the preparations containing iron, whether the slight or doubtful symptoms were

TABLE II—INCIDENCE OF ALL GASTROINTESTINAL SYMPTOMS IN 93 SUBJECTS WHO COMPLETED THE TRIAL

Iron preparation	1 No symptoms	2 Slight or doubtful symptoms	3 Symptoms +	4 Symptoms ++	5 Total with significant symptoms (3+4)	6 Total with no significant symptoms (1+2)
Ferrous sulphate	58	12	22	1	23	70
" gluconate	69	4	17	3	20	73
" succinate	59	13	19	2	21	72
calcium citrate	63	11	14	5	19	74
"Unknown control	65	8	18	2	20	73
'Known' control	91	0	2	0	2	91

+ = symptoms definite but treatment continued. ++ = symptoms severe enough to stop treatment with that pill

TABLE III—INCIDENCE OF SYMPTOMS ATTRIBUTED TO IRON PILLS

(Group A 20 subjects who complained of symptoms with "unknown" control pills Group B 73 subjects who did not complain)

Iron preparation	Total no	No with definite symptoms	Intolerance rate (%)
Group A			
Ferrous sulphate	20	10	50
" gluconate	20	8	40
" succinate	20	5	25
" calcium citrate	20	7	35
Group B			
Ferrous sulphate	73	13	18
" gluconate	73	12	16
" succinate	73	16	22
" calcium citrate	73	12	16

included in the analysis or not (P>0 05) Only 2 volunteers recorded symptoms while taking the "known" control pills, 1 complained of heartburn and 1 of constipation When the incidence of side-effects was calculated for the whole group of 103 (using the incomplete replies of the 10 nurses who failed to complete the trial) there was again no significant difference between iron preparations and "unknown" control pills

It was clear that factors other than iron were responsible for most of the "toxicity" reported by these volunteers One possibility was that a proportion of them were unusually suggestible, and developed symptoms whenever they took pills which they believed to contain iron If this were so, it would be important to exclude such subjects from consideration when comparing the iron preparations

To test this hypothesis the 93 who completed the trial were divided into two groups—the 20 nurses who complained of symptoms with "unknown" control pills (group A), and the 73 who did not (group B) Table III shows that there was more intolerance to iron-containing pills in group A than in group B, and in the case of ferrous sulphate and ferrous gluconate this difference was significant (P<0 05) In group B the intolerance-rates to the four iron preparations did not differ significantly from one another

Analysis of the individual symptoms reported with the various iron pills shows that no characteristic symptom complex resulted from taking any of the pills With each preparation, constipation and abdominal discomfort were the commonest symptoms, the incidence of all the others was less than 10%

11 of the subjects who did not complain of symptoms with control pills had symptoms with more than one of those containing iron 3 of them reported constipation with each of two preparations, but otherwise there was no consistency in the symptoms of which any individual complained Nobody reported symptoms with all four iron preparations There was therefore no evidence of the occurrence of true iron intolerance embracing all forms of oral iron

DISCUSSION

The importance of psychological factors in producing both beneficial and undesirable results from drug therapy is now widely recognised

Girdwood (1952) focused attention on this aspect of iron intolerance In a clinical trial of molybdenised ferrous sulphate he found that many patients who were intolerant of ferrous sulphate had no symptoms when taking the preparation containing trace amounts of molybdenum Realising that this might be partly due to the difference in appearance between the pills, he administered ferrous sulphate, in the form of white pills, to 16 patients who had previously developed gastrointestinal symptoms when taking exactly the same preparation in the form of green pills ('Fersolate') 14 of the 16 took white ferrous-sulphate pills without complaint

Edgar and Rice (1956) used similar white ferrous-sulphate pills in the prophylaxis of anæmia of pregnancy, and found a much lower intolerance-rate than most other investigators using the green pills

Two main factors contribute to this finding

Firstly, mild gastrointestinal disturbances, particularly constipation, are common in any group of young women, and particularly in the pregnant women, who in Great Britain form the majority of the patients receiving iron therapy There is a strong tendency for the patient to attribute these symptoms to any medicine she *is taking*, especially if she knows that it may have such effects This tendency may have been accentuated in the present trial since the volunteers were specifically asked to note any gastrointestinal disturbance, and their attention was directed to likely symptoms by the questionnaire That transient incidental symptoms were responsible for many of the "toxic effects" reported is suggested by the observation that more than half the nurses who complained of symptoms with "unknown" control pills had *no symptoms when taking* one or other of the iron preparations

Secondly, suggestible people can develop symptoms of psychological origin, not previously present, when taking pills which they believe will upset them

This phenomenon is observed in most clinical trials, and the proportion of subjects who exhibit it may be surprisingly high In a trial of phenoxybenzamine for the treatment of chilblains (College of General Practitioners 1957) 13% of the patients taking placebo pills complained of dizziness or other symptoms which they had been warned might occur with phenoxybenzamine In a similar long-term trial of tetracycline (Moyes and Kershaw 1957) 39% of those receiving *placebos complained* of diarrhœa

In the present investigation the incidence of symptoms in the group as a whole was almost the same, whether the iron was taken as ferrous sulphate, ferrous gluconate, ferrous succinate or ferrous calcium citrate Similar "toxic effects", however, were reported equally often after taking the "unknown" control pills which were thought to contain iron but in fact contained only lactose It is of great interest that with the "known" control pills (identical in every way with the "unknown") only 2 subjects reported symptoms This observation may be interpreted in two ways either (1) most of the subjects experienced no symptoms while taking the "known" control pills, or (2) the symptoms arose, but, because they could not be ascribed to the pills, were ignored or attributed to other factors

Our impression that the "toxic effects" of the pills were not due to iron is strengthened by our finding that no symptom or group of symptoms was constantly associated with any particular preparation of iron and that, when they were on iron therapy, none of the subjects consistently complained of symptoms distinguishable from those they reported when "unknown" inert pills were taken

It should be emphasised that the conditions in this trial were not identical with those in clinical practice

Firstly, the dose of iron chosen for the trial approximated closely to that used in practice when commercial preparations *of ferrous gluconate* and ferrous succinate are prescribed, but was about *half that usually* employed when ferrous sulphate is prescribed Secondly, the pills were given for only five days at a time (This period was thought long enough *for* symptoms due to gastrointestinal irritation to appear) Thirdly, this trial differed from previous therapeutic trials in that the people taking part in it were neither anæmic nor pregnant We would, however, point out that we obtained almost identical results in a similar trial on pregnant women (Kerr and Davidson 1958)

We conclude that a large proportion of the symptoms experienced during therapy with oral iron preparations is psychological in origin The possibility that some patients have true iron intolerance cannot be excluded, but the incidence of toxicity—at least with doses of 35 mg of iron three times a day—must be very low Among those whose complaints were confined to iron preparations, the symptom most commonly reported was constipation Other gastrointestinal effects were variable, and usually mild, and they were never reported by more than 12% of subjects

It will take a long time to dispel the popular belief that iron pills inevitably cause unpleasant side-effects, but reassurance and enthusiastic propaganda could do a great deal to reduce the "intolerance rate" Recently we have found it well worth while to explain to patients that the pills they are about to take have been tested in a blind trial and found to cause no more symptoms than pills containing sugar

Summary

1 Ferrous sulphate, ferrous gluconate, ferrous succinate, ferrous calcium citrate, and "known" and "unknown" control pills (containing lactose) were administered to 93 healthy young women in a double-blind trial The incidence of gastrointestinal symptoms attributed to the pills was assessed from the replies to a questionnaire

2 Virtually no toxic effects were reported from "known" control pills containing lactose, but the exactly similar "unknown" control pills, which were thought by the subjects to contain iron, produced as many side-effects as the pills which did in fact contain it

3 None of the four iron compounds was found to be significantly more "toxic" than inert pills containing lactose Hence it was concluded that intolerance to these iron preparations, in the dosage given, was mainly psychological in origin

We wish to express our thanks to the nurses who took part in the trial and to Miss Law, assistant lady superintendent, Royal Infirmary, Edinburgh, who helped to recruit the volunteers, to Dr Gordon Fryers, of John Wyeth and Brother, Ltd for the supply of ferrous sulphate, ferrous gluconate, and control pills, to Mr John Williams, of Calmic Ltd for the supply of ferrous succinate, and to Mr Reginald George, of Ortho Pharmaceuticals Ltd for the supply of ferrous calcium citrate, used in the trial

ACCIDENTAL HYPOTHERMIA

A COMMON CONDITION WITH A PATHOGNOMONIC ELECTROCARDIOGRAM

D EMSLIE-SMITH
M D Aberd , M R C.P
TUTOR IN CLINICAL MEDICINE IN THE UNIVERSITY OF ST ANDREWS, QUEEN'S COLLEGE, DUNDEE

INDUCED hypothermia now plays an accepted part in surgery of the heart and brain and has therefore been studied a great deal by physiologists (Kayser 1957) Clinicians, however, have paid comparatively little attention to accidental hypothermia, and Rees (1958), who recently reported four cases, has stated that in clinical medicine it is uncommon

The electrocardiogram in preoperative hypothermia has features characteristic enough to be pathognomonic (Emslie-Smith 1956, Fleming and Muir 1957) As temperature falls, the heart-rate slows, and the intervals PR, QRS, and QTC all lengthen A conspicuous extra deflection appears at the junction of the QRS complex and the ST segment This "junction deflection" (J deflection) is slowly inscribed and is usually most obvious in lead V4, where it is directed upward In other leads the base of the QRS complex is widened In the vectorcardiogram these features are represented by an extra loop between the QRS and T loops (Emslie-Smith 1958) When the J deflection is large, the T wave may become inverted

Tomaszewski (1938) published the electrocardiogram of a vagrant dying from cold Since then the electrocardiogram in accidental hypothermia seems to have been recorded on eight occasions only (Wayburn 1947, Graybiel and Dawe 1948, Laufman 1951, Karnell *et al* 1955, Biorck and Johansson 1955, Rees 1958) Only a few of these records showed the characteristic J deflection, and Rees (1958) did not see it in the electrocardiograms of his patients

I have recently encountered eight cases of accidental hypothermia, and heard of another, in circumstances which suggest that the condition is very much commoner than is supposed In seven cases adequate electrocardiograms showed the pathognomonic pattern, in the eighth it was obscured by bundle-branch block

Case-reports

Case 1 —A mentally depressed woman, aged 50, was found unconscious It was thought that she had swallowed a large dose of carbromal and barbiturate She was cyanosed and deeply comatose, with shallow respirations occurring only three times a minute All her tendon-reflexes were absent, her systolic blood-pressure was 60 mm Hg, and her rectal temperature was 30 2°C (86°F)

An endotracheal tube was passed, and oxygen was given by artificial respiration with a closed circuit An intravenous infusion of plasma was started The electrocardiogram then showed sinus bradycardia (rate 47 a minute). Changes typical of hypothermia were present PR measured 0 16 sec., QRS 0 08 sec , and QTC 0 57 sec , a small, slowly inscribed, extra deflection was present between QRS and the early part of the ST segment (J deflection), it was directed upward in leads I, II, III, aVL, aVF, V4, and V6, and downward in lead aVR

The patient died after 48 hours' coma

Case 2 —A grossly myxœdematous woman, aged 75, was found naked and unconscious Her heart sounds were faint, blood-pressure 150/90 mm Hg, and respirations 20 a minute. There were no focal neurological signs Her rectal temperature was 27°C (80 6°F) The electrocardiogram showed sinus rhythm (rate 30 a minute) It was characteristic of hypothermia PR measured 0 19 sec , QRS 0 11 sec , and QTC 0 58 sec , in leads aVL, V4 and V5 a small J deflection was present between QRS

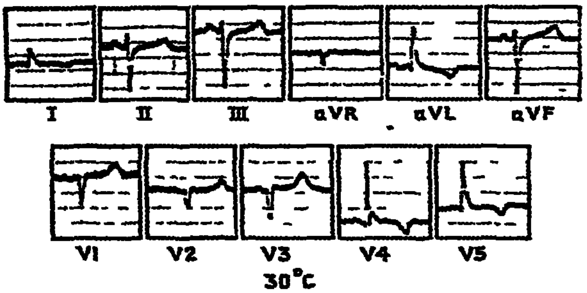

Fig 1—Electrocardiogram in case 3 with rectal temperature 30 C (86 F) Note QTc interval prolonged (0 53 sec.), typical J deflection prominent in lead V4, base of QRS widened in leads I, aVL, aVF, V5, and T inverted in leads I, aVL, V4, and V5

and the early part of the ST segment T was directed downward in leads I, II, III, aVF, V4, and V5, and upward in leads aVR and aVL. Despite gross myxoedema the amplitude of the complexes was not reduced R in lead I, for example, measured 1 35 mV

Warming and the administration of triiodothyronine were ineffective. The patient died about 12 hours after admission.

At necropsy the thyroid gland was small and fibrotic, and the plasma-cholesterol level was 550 mg per 100 ml, there was some hypertrophy of the left ventricle, and there was patchy atheroma of the coronary arteries without occlusion of the lumen

Case 3—A one-legged woman, aged 82, was found lying neglected and stuporous in front of an unlit fire She had a black eye on the left side, and radiography showed a small fracture above the left orbit She had multiple abrasions, and gangrene of the right foot Her blood-pressure was 120/100 mm Hg, and rectal temperature 30°C (86 F)

Electrocardiograms showed mechanical artefacts caused by muscular tremor There was sinus rhythm (rate 42 a minute) The typical changes of hypothermia were present PR measured 0 20 sec, QRS 0 05 sec, and QTc 0 53 sec, a typical large J deflection was present in V4, T was inverted in leads I, aVL, V4 and V5, there was widening, with ledging, of the base of QRS in leads I, aVL, aVF, and V5 (fig 1)

The patient died about 12 hours after admission. Necropsy showed ulcerating atheroma of the thoracic aorta and multiple small infarcts in spleen and kidneys The left ventricle was hypertrophied. The cerebral cortex was slightly atrophied

Case 4—A diabetic man, aged 80, who was well cared for at home, began to have hypoglycaemic attacks, for which he came to hospital His dose of insulin-zinc suspension was adjusted Two days after discharge he behaved oddly and fell He was put to bed and given sugar, but his manner remained peculiar all evening At 2 A.M. he "seemed to have settled", but at 7 A.M. he was found wet, half out of bed, and without bedclothes

He was stuporous, with corpse-like pallor and unusually firm subcutaneous tissues His blood-pressure was 115/50 mm Hg, and his respirations were 16 a minute His limbs were held rigid His tendon-reflexes were all present, but his muscles contracted slowly His rectal temperature was 25 75°C (78 3°F)

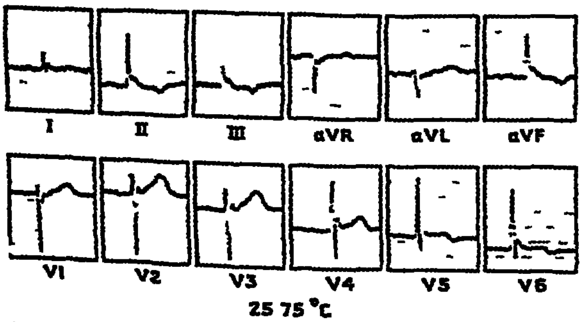

Fig 2—Electrocardiogram in case 4 with rectal temperature 25 75 C (78 3°F) Note QTc interval prolonged (0 54 sec) typical J deflection directed upward in leads I II, and V2–V6 and downward in lead aVR, base of QRS widened in leads III and aVF and T inverted in leads II, III, aVF, V5, and V6, and flat in lead I.

The electrocardiogram was distorted by a fine mechanical artefact caused by muscular tremor There was sinus rhythm (rate 48 a minute) The characteristic changes of hypothermia were present PR measured 0 24 sec., QRS 0 07 sec., and QTc 0 54 sec, there was a conspicuous J deflection, directed upward in leads I, II, and leads V2–V6, and downward in lead aVR, T was inverted in leads II, III, aVF, V5, and V6 and flat in lead I, there was widening of the base of QRS in leads III and aVF (fig 2)

The patient was given intravenous glucose and prophylactic penicillin and was heated under an electric blanket 24 hours later his rectal temperature was 31 75°C (89 2 F) and his physical state more normal His blood-sugar level was 134 mg per 100 ml and blood-urea level 73 mg per 100 ml The signs of hypothermia in the electrocardiogram were less conspicuous, but a J deflection was still present, directed upward in leads I, II, aVF, V5, and V6, and downward in lead aVR T was inverted in leads aVF and III The base of QRS was widened in leads III and V1

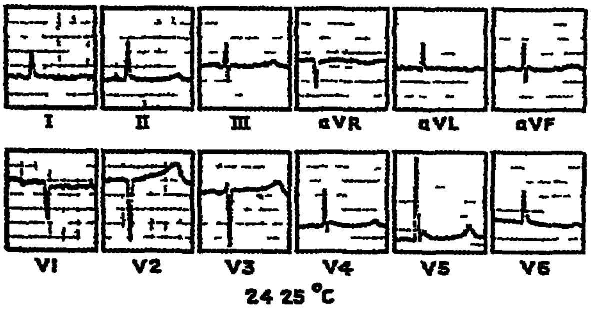

Fig 3—Electrocardiogram in case 5 with rectal temperature 24 25 C (75 6 F) Note QTc interval prolonged (0 60 sec.), typical J deflection in leads aVF, V4, and V5, base of QRS widened in lead V6, and T flat in lead aVL and diphasic in lead V6.

About 60 hours after admission the patient's temperature was 37°C (98 6°F), pulse-rate 100, and respirations 30 a minute Although no longer stuporous he was confused His temperature rose to 39 5 C (103 F), and signs of bronchopneumonia appeared. Electrocardiograms now indicated anterolateral myocardial ischaemia He died 5 days after admission.

Case 5.—Within a few weeks of beginning to live on her own, a woman, aged 72, was found lying unconscious on the floor Relations said she had become increasingly confused and breathless and had felt the cold badly She had occasionally been dizzy and had sometimes fallen.

She was cyanosed and comatose, with rectal temperature 24 25 C (75 6 F), and respirations 12 a minute, expiration prolonged and grunting Her radial pulse could not be felt, and no blood-pressure could be recorded. The outer halves of her eyebrows were thin, her protruded tongue was thick, and her skin was dry and scaly Her facial subcutaneous tissue was thick. All her limbs were rigid, but she grimaced and moved her arms slowly Her pupils reacted sluggishly to light Her tendon-reflexes were present, but her muscles contracted slowly Both her legs were oedematous, with large varices

The electrocardiogram was distorted by tremor but showed sinus rhythm (rate 36 a minute) There were characteristic changes of hypothermia PR measured 0 24 sec., QRS 0 06 sec., and QTc 0 60 sec, a J deflection was present in leads II, III, aVF, V4, and V5, T was flat in lead aVL and diphasic in lead V6, in lead V6 the base of QRS was widened (fig 3)

After the patient had been warmed all night, her rectal temperature had risen to 32°C (89 6 F) and she seemed better She answered simple questions slowly with a hoarse voice Her systolic blood-pressure was 60 mm. Hg, and pulse-rate 62 No cardiac murmurs were heard The electrocardiogram showed right bundle-branch block and ventricular ectopic beats Myxœdema was diagnosed, but despite the administration of cortisone and triiodothyronine she deteriorated and died

At necropsy the thyroid gland was small and fibrous There was aortic stenosis and incompetence, with left ventricular hypertrophy, and bronchopneumonia

Case 6 —A woman, aged 81, who lived alone, was thought by her neighbours to be unwell Her doctor found her unsteady, with slurred speech, wondered if she had taken too many sleeping tablets, and put her to bed Next day she was found, clad only in a nightdress, confused and cold, with a black eye On admission to hospital she was comatose, with a large contusion and laceration of the left supraorbital region Her rectal temperature was 27 5°C (81 5°F), respirations 16 a minute, and blood-pressure 120/80 mm Hg Her pupils reacted sluggishly to light Her limbs were rigid and flexed, and her tendon-jerks were present but typically slow She had a single generalised convulsion, with conjugate deviation of her eyes to the right Radiography showed no fracture of skull

The electrocardiogram showed considerable clockwise rotation of a vertical heart and sinus rhythm (rate 72 a minute) The record was characteristic of hypothermia PR measured 0 24 sec, QRS 0 04 sec, and QTC 0 49 sec, a J deflection was present in leads II, III, and aVF, T was flat, and the base of QRS was widened, in leads V7 and V8

After the patient had been warmed for four hours, her rectal temperature was 30°C (86°F) and atrial fibrillation was noted Later hemiplegia and upper-motor-neurone paralysis of the seventh cranial nerve appeared on the left side Lumbar puncture yielded normal cerebrospinal fluid under normal pressure The patient's temperature rose to 38 3°C (101°F), signs of bronchopneumonia appeared, and she died

Necropsy showed subdural hæmatoma in the right occipital region and atherosclerosis of the cerebral arteries

Case 7 —Every winter for about 14 years a woman, aged 64, had become cold and lethargic, with slowing of mental and bodily activities During these periods, which her relations described as " hibernation ", she was sometimes stuporous or even comatose, and she was often admitted to hospital, where various provisional diagnoses were made and different treatments given During a spell of cold weather in early spring she again became cold and retarded and was admitted to hospital

She was stuporous, answering simple questions with monosyllables only Although her eyebrows were thin, her pubic hair was thick, and she did not look frankly myxœdematous Her skin was cold and dry, and the subcutaneous fat felt doughy Her pupils reacted slowly to light Her muscular tone was increased, and, although her tendon-reflexes were not increased in amplitude, her muscles contracted slowly after percussion of the tendon Her pulse-rate was 60, and respirations were 13 a minute The first and second heart sounds were unduly widely separated Her blood-pressure was 118/70 mm Hg and her rectal temperature was 33°C (91 4°F) Her serum-cholesterol level was 420 mg per 100 ml, this fact strongly supported the diagnosis of hypothyoidism

The electrocardiogram was slightly disturbed by muscular tremor and showed considerable clockwise rotation of the heart There was sinus rhythm, with occasional ventricular ectopic beats The typical changes of hypothermia were present PR measured 0 18 sec, QRS 0 06 sec, and QTC 0 42 sec, there was a prominent J deflection in leads V2, V3, and V4, T was inverted in leads II, III, aVR, aVF, and chest leads V2–V5, and flat in leads I and V1, there was widening of the base of QRS in leads I, III, and aVL

Warming her slowly in an electric blanket raised her temperature to 37°C (98 6°F) over 24 hours, but her general condition deteriorated, and she became comatose, with blood-pressure 80/50 mm Hg Treatment with triiodothyronine and cortisone produced a steady improvement, but she developed pyrexia and signs of bronchopulmonary infection and died a week after admission

At necropsy the thyroid gland was small (10 g), the heart was dilated, and there was focal acute and chronic pancreatitis

Case 8 —A woman, aged 86, who lived alone, was noticed to be confused Next day she was found comatose, with shallow respirations 16 a minute, blood-pressure 50/30 mm Hg, and rectal temperature 26 5°C (79 7°F) She had severe kyphoscoliosis, with dullness on percussion of the left hemithorax, coarse crepitations were heard over the right side of her chest Her pupils were small and did not react to light Her right plantar response was flexor, there was no response on the left

The electrocardiogram showed sinus rhythm (rate 30 a minute) PR measured 0 44 sec, QTC 0 61 sec In leads I and aVL a tiny R was followed by a wide deep slurred S In lead V1 and V2 a small Q was followed by a wide slurred R and an inverted T, in leads V5 and V6 a large R was followed by a deep wide slurred S and upright T These findings were interpreted as evidence of right bundle-branch block, possibly with anteroseptal infarction However, lead V3 showed a small R, then a rounded larger deflection which might have been a J deflection, T was inverted Lead V4 showed a larger R followed by a smaller rounded deflection (possibly J) and an inverted T Leads aVF and III showed what would have been interpreted, in the absence of right bundle-branch block, as the J deflection and inverted T of hypothermia

Warming was begun, but the patient died a few hours after admission

Discussion

In patients made hypothermic before operations on the heart or the brain a temperature of 28–30°C is achieved by elaborate medication and cooling Seven of my patients with accidental hypothermia had rectal temperatures between 30 2°C and 24 25°C (mean 27 2°C, S D 2 2)

Six of the patients were admitted to hospital within two winter months, and in all of them accidental hypothermia was diagnosed by physicians who had already taken special interest in the subject In none of the patients, however, was the actual depth of hypothermia appreciated until the accurate rectal temperature was taken by a laboratory thermometer or a thermistor recorder These facts suggest that the condition is very much commoner than is generally supposed, and that it is often unrecognised despite distinctive clinical features and a pathognomonic electrocardiogram

Rees (1958) has stated that hypothermia is a hazard of the extremes of life, and it is significant that, if the case of suicide is excluded, the mean age in this series was 77 (S D 6 9) Five of the patients lived alone, and this fact, too, is important, although case 4 shows that hypothermia can develop rapidly even without neglect It is clear from the case-reports that a British bedroom in winter is cold enough to make an elderly person with impaired cerebral function severely hypothermic, especially if he lies wet and partly clad

The clinical effects of hypothermia in man are characteristic (Alexander 1946) The patient has a waxy pallor, but the superficial veins are not necessarily collapsed The respirations are slow, with prolonged expiration The heart beats slowly, the blood-pressure may be low, and atrial fibrillation may develop Consciousness is clouded or lost There are muscular rigidity and tremor, and the tendon-reflexes are characteristically delayed and prolonged, but not diminished The pupils are dilated, and their reaction to light is poor At lower temperatures rigidity and tendon-reflexes disappear, respiration ceases, and death takes place usually when the temperature falls to 24–26°C, one patient has survived a temperature of 18°C (Laufman 1951) Most of the features were present in all my patients Although shivering was not often evident clinically, a fine muscular tremor produced an almost constant mechanical artefact in the electrocardiogram

It is important to recognise the clinical picture of hypothermia because it may disguise that of the underlying condition and thus delay full diagnosis and adequate treatment

The changes in the electrocardiogram found in various degrees in seven of my patients are identical with those constantly found in induced hypothermia in patients with normal hearts (Emslie-Smith 1956) and analogous to those seen in experimental hypothermia in dogs (Emslie-Smith et al 1958) The lengthening of the RR, PR, QRS, and corrected QT (QTC) intervals, the presence of the typical J deflection, with or without inversion of T, in leads related to the left ventricle, and the widening of the base of QRS in other leads, together constitute a pathognomonic pattern. The J deflection is almost always most conspicuous in left chest leads, especially lead V4 If adequate electrocardiograms with chest leads are not recorded, the J deflection may be missed, this is probably why it has not previously been recorded in accidental hypothermia with any constancy

Atrial fibrillation developed at a mean temperature of 28 9°C in six of ten patients with normal hearts during the production of preoperative hypothermia (Emslie-Smith et al 1958) By contrast it developed in only one of the eight cases of accidental hypothermia

The finding of the typical pattern in the electrocardiogram of a stuporous patient should suggest hypothermia Thus in case 3 the diagnosis was initially made from an electrocardiogram recorded to exclude a cardiac infarct or heart-block. It is, of course, easier to take the rectal temperature with a laboratory thermometer than to record the electrocardiogram, and probably the best way to diagnose accidental hypothermia is to remember the fact that it may complicate any state of impaired consciousness in an elderly patient

Summary

Accidental hypothermia has recently been diagnosed nine times in elderly patients in circumstances which suggest that it is much commoner than is generally supposed

The electrocardiogram showed a pattern pathognomonic of hypothermia in seven of the eight cases in which it was recorded in the eighth case the typical features were masked by bundle-branch block

The RR, PR, QRS, and QTC intervals were lengthened The characteristic J deflection of hypothermia was present in leads related to the left ventricle, when it was conspicuous, T was sometimes inverted In other leads the base of QRS was widened These changes were identical with those constantly seen in induced hypothermia in patients with normal hearts and analogous to those found in experimental hypothermia in dogs

Failure to use adequate leads, especially left chest leads, probably explains why this pathognomonic pattern has not been constantly found in accidental hypothermia

I wish to thank Prof I G W Hill, Mr Walter Campbell, Dr Robert Semple, Dr J M Stowers, and Dr R R Andrew for permission to study and report these cases

Since the clinical use of the Δ^1 analogues of cortisone (prednisone and prednisolone) was first reported by Bunim et al in 1955, further efforts have been made to produce analogues which would have equal or greater efficiency as anti-inflammatory agents but fewer unwanted effects, particularly gastroduodenal ulceration The advantage of the Δ compounds was that they caused less salt and water retention than cortisone or hydrocortisone, while being clinically effective in approximately a fifth of the dose It was not long before new compounds appeared, and at the 9th International Congress of Rheumatology in Toronto last year the clinical effects of two more were reported—namely, triamcinolone (16-α-hydroxy, Δ^1, 9-α-fluorohydrocortisone) (fig 1) by Freyberg et al (1957) and medrol (6-methyl prednisolone) by Boland and Liddle (1957) The former substance is the subject of this report

Fried (1955) found that substitution of a fluorine or chlorine atom at C9 in the hydrocortisone molecule produced an increase in the glucocorticoid action and a greater increase in mineralocorticoid or sodium-retaining effect Apart from external application for skin disorders, this substance, 9-α-fluorohydrocortisone (fludrocortisone), is now used only in salt-losing cases of Addison's disease or after adrenalectomy In 1953 Hirschmann et al reported that, by adding a hydroxyl group to deoxycortone (Doca) at C16 in the α position, the characteristic salt-retaining activity of this substance was eliminated Three years later Bernstein (1956) reported that by adding a 16-α-hydroxyl group to the powerful 9-α-fluorosteroids their sodium-retaining potency was lost without decrease of glucocorticoid activity Addition of the 16-α-hydroxyl group not only failed to produce sodium retention, but actually caused sodium excretion and diuresis while glucocorticoid activity was retained This particular virtue did not impress us as constituting a great clinical advance on prednisone or prednisolone, except perhaps for patients with cardiac decompensation who were unable to tolerate the former substances What interested us more was the suggestion in early reports that certain side-effects—i.e, peptic ulceration, mental disturbances, and osteoporosis—were less with triam-

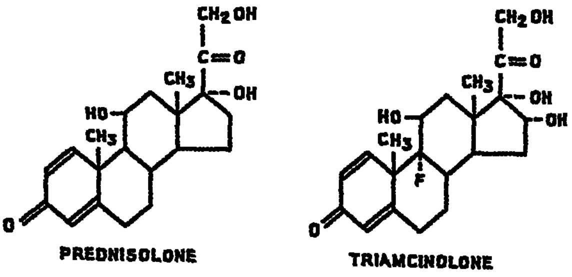

Fig 1—Prednisolone and triamcinolone.

was there any significant alteration in sedimentation-rate or finger tenderness In 11 patients subjective estimation of pain and stiffness was unchanged, 3 improved on prednisolone, and 11 on triamcinolone, but in only 5 was the improvement with triamcinolone more than slight Grip measurement was unchanged in all but 5 who improved on triamcinolone Finger swelling was also unchanged except in 5, who also improved on triamcinolone 7 patients had indigestion, in 3 it improved on triamcinolone, in 3 it became worse, and in 1 it was unchanged There were no acute "rebound" symptoms on transfer from prednisolone to triamcinolone or vice versa No significant weight changes occurred with either drug, though 1 patient had a consistently increased urinary output on triamcinolone, and 1 noticed diminished swelling not only in the affected joints but also in a swollen (previously thrombosed) leg In the case of psoriatic arthropathy the skin condition improved only with triamcinolone, and then strikingly 1 diabetic passed more sugar on triamcinolone than on prednisolone, and the blood-sugar level rose with triamcinolone 3 patients noticed hot feelings in the face and neck after meals only when taking triamcinolone In 2 patients who had had prednisolone for over two years, large striæ appeared on the abdomen within fourteen and twenty-one days of changing to triamcinolone Our patients on triamcinolone did not complain particularly of anorexia, headache, and lassitude, which have been reported by other observers About half the patients preferred triamcinolone to prednisolone, but the difference was slight except in 5 This may have been partly because a differently shaped tablet gave the impression of a new form of therapy Patients with rheumatoid arthritis are an optimistic group 3 cases are of particular interest

Case 26—A woman, aged 58, with a thirteen-year history of rheumatoid arthritis, had had steroid therapy for six years Recently, on prednisone 5 mg q d.s , vascular-necrotic lesions appeared on the hands and feet On May 5, 1958, she was given triamcinolone 4 mg q d.s , with an estimated subjective improvement of 15% A week later she had an episode of vomiting, possibly dietetic in origin, and was put back on to prednisone On May 24 triamcinolone 4 mg t d s was again substituted, and in the early hours of May 29 a gastric ulcer perforated During operation, which was successful, she had intramuscular cortisone in high dosage, and she has since remained well on oral hydrocortisone 60 mg daily

Case 27—A housewife, aged 54, developed severe and disabling rheumatoid arthritis in 1954 Cortisone 75 mg daily produced some improvement initially, and she has taken steroids ever since Her condition has gradually deteriorated though there was a temporary improvement when prednisolone was given in 1955 A year later a lumbar vertebra collapsed because of osteoporosis, meanwhile a moon-face was becoming more noticeable In April, 1958, triamcinolone 12 mg daily was substituted for 15 mg of prednisolone Since then her moon-face has become worse, and prominent striæ have appeared on the flanks and both breasts

Case 23—A woman, aged 38, with four months' history of acute rheumatoid arthritis was treated in hospital with prednisolone 5 mg b d., and improved greatly Five months later she became pregnant, and the rheumatoid arthritis worsened steadily in spite of increase of prednisolone to 17 5 mg daily, which caused mild indigestion She was again admitted to hospital and after a week there was little improvement Triamcinolone 14 mg daily was started, and during the next week there was a 50% improvement in her general condition, with a 25% increase in grip and reduction in finger swelling by 19 ring sizes The indigestion subsided.

Comment—This case illustrates the definite improvement in some patients who are transferred to triamcinolone Pregnancy apparently caused this patient's relapse This is the reverse of what is usually seen, but such cases are not uncommon

Systemic (Disseminated) Lupus Erythematosus

3 patients with systemic lupus erythematosus have been treated for periods of two to eight weeks on triamcinolone

Case 28—In 1949 a housewife, now aged 55, developed what was thought to be rheumatoid arthritis Cortisone therapy was begun two years later In 1954, following its abrupt withdrawal, she became acutely ill, with vomiting, abdominal pain, and fever, and lupus erythematosus cells were found in the blood There was a good response to prednisolone, which she took throughout 1957—usually 15 mg daily in divided doses—but there were several episodes of vomiting when it became necessary to increase the dose. Despite rigid salt restriction, she gradually became moon-faced and hypertensive

At the end of 1957 she developed severe and persistent back pain. In February, 1958, X-ray films of the spine were satisfactory, and her daily dose of prednisolone was increased to 25 mg Two months later it was reduced gradually to 15 mg daily, and then triamcinolone 12 mg daily was substituted Her back pain, however, became worse, and in May there was gross radiographic osteoporosis, with crush fractures of vertebræ and fractured ribs She has now had triamcinolone for eight weeks, her face is becoming more moon-like and striæ have appeared on her flanks

Comment—The osteoporosis was probably associated with increased prednisolone dosage There is no evidence that triamcinolone is alleviating the features of Cushing's syndrome, and it may be making them worse

The treatment of 2 other patients with disseminated lupus erythematosus has also been changed from prednisolone to triamcinolone and back to prednisolone without any significant alteration in their condition

Ulcerative Colitis

In 2 patients with ulcerative colitis 12 mg of triamcinolone daily was substituted for 15 mg of prednisolone Triamcinolone was continued for a week, and then prednisolone was given again In both cases the patients' subjective wellbeing, the number of stools and their consistence, and the amount of bleeding remained unaltered

Discussion

On the results of this short-term survey there seems little to choose between triamcinolone and its predecessors in the treatment of rheumatoid arthritis In our small series there was no real difference in aggravation or amelioration of dyspeptic symptoms, for 3 patients improved and 3 worsened when given triamcinolone The most important of all the so-called side-effects of steroid therapy—namely, dyspepsia with or without peptic ulceration—is not a fundamental or common feature of idiopathic Cushing's syndrome The possibility remains that variations of the cortisone molecule may result in the production of a therapeutically effective glucocorticoid with a lower incidence of gastroduodenal side-effects Long-term studies will reveal whether there is any appreciable diminution in incidence of these side-effects with triamcinolone or not

Two serious reactions—multiple crush fractures of vertebræ, and perforation of a peptic ulcer—were seen in our series on triamcinolone As both patients had been receiving full dosage with prednisolone for a long time before, one cannot say which steroid was particularly at fault, though in the former the period of increased prednisolone dosage was probably responsible

What then are the advantages, if any, of this new substance? Triamcinolone is another effective steroid with no particular virtue except that it does not cause salt and water retention. It appears to have certain mild side-effects unlike those seen with the previous Δ compounds, but, apart from postprandial flushing, these were not seen in our present small, short-term series The incidence of serious side-effects will have to be assessed on larger numbers

Where there was any advantage in changing from one drug to another it usually lay with triamcinolone, but the difference was small In a few cases objective physical signs improved on triamcinolone, but again the differences were usually slight

Summary and Conclusions

The treatment of 24 patients with rheumatoid arthritis and 1 with psoriatic arthropathy was changed from prednisolone to triamcinolone and (after a period of five to seventy days) back to prednisolone The dose ratio of triamcinolone to prednisolone was 4/5 Of these 25 patients, 11 preferred triamcinolone to prednisolone, 3 preferred prednisolone to triamcinolone, and 11 were indifferent

Measurement of sedimentation-rate and digital tenderness remained unchanged Finger swelling and grip strength altered in only 5 patients, each of whom improved on triamcinolone

There were no acute "rebound" symptoms on changing to either drug In only 5 cases was subjective improvement more than slight—in each case in favour of triamcinolone

Of 7 patients who complained of dyspepsia on prednisolone, 3 improved when transferred to triamcinolone, and 3 deteriorated

In 3 cases previously treated with prednisolone for over two years abdominal striæ appeared within three weeks of changing to triamcinolone 3 patients noticed postprandial flushing on triamcinolone, but not on prednisolone

The case-histories are presented of 3 patients with rheumatoid arthritis and 1 with systemic lupus erythematosus 2 others with the latter disease and 2 with ulcerative colitis were given triamcinolone without any change in their condition

Although triamcinolone does not differ greatly in its therapeutic action or in its undesirable side-effects from prednisolone it is useful to have another effective steroid available

Our thanks are due to the Lederle Laboratories Division of the American Cyanamid Company for supplies of triamcinolone ('Ledercort')

TRIAMCINOLONE ARTHRITIS?

Ronald Wells
M B, B Sc Lond, M R C P, D T M & H
From the Department of Medicine, General Hospital, Singapore

Triamcinolone was synthesised by Bernstein et al (1956) Early clinical studies have shown it to be therapeutically active in many conditions previously known to respond to cortisone, prednisone, and prednisolone (Hellman et al 1957, Sherwood and Cooke 1957, Rein et al 1957), and its therapeutic potency has been assessed as twice that of prednisolone (Sherwood and Cooke 1957)

When a supply of triamcinolone became available in Singapore, its clinical value was assessed in fourteen patients with various different conditions requiring corticosteroid maintenance therapy All had been receiving optimal doses of prednisolone, as determined by trial and error, with individual adjustments to give the best therapeutic response without producing any important side-effects Three of these patients had rheumatoid arthritis and two had systemic lupus erythematosus None of the others had ever noticed pain or stiffness in their joints, yet three of them developed arthritis, apparently as a result of the administration of triamcinolone This complication has not been described previously

Case-reports

Case 1.—A European woman, aged 23, had thrombocytopenic purpura She gave a 3 months' history of bruising and of menorrhagia Her hæmorrhagic diathesis responded well to prednisolone therapy, but a daily dose of 5 mg was necessary The only objective side-effects of this treatment were pronounced hirsutism and slight acne, but on questioning she stated that her libido was increased and orgasms were facilitated

After 6 months prednisolone was stopped and she was given triamcinolone 2 mg daily Within 24 hours she developed "flitting rheumatic pains" in her left shoulder, right elbow and wrist, and both feet She had no fever, tachycardia, or excessive sweating The erythrocyte-sedimentation rate (E S R) was 5 mm (Westergren) The administration of triamcinolone was continued and she was given codein co *B P* 2 tablets every 4 hours The pains decreased over the next 2 days and the analgesic tablets were discontinued After a month on triamcinolone her fingers showed swelling, typical of early rheumatoid arthritis, around the metacarpophalangeal and proximal interphalangeal joints The range of movement of her shoulder, knee, and elbow joints were all diminished The E S R was still 5 mm During the same period the thrombocytopenia recurred and she again began to bruise easily

When triamcinolone was replaced by prednisolone 10 mg daily, the swelling and stiffness of her joints rapidly disappeared, the thrombocyte-count increased, and she ceased bruising easily

Case 2—An Indian girl, aged 17, had 6 years' history of progressive bronchial asthma She was stunted and pigeon-chested Initial treatment with cortisone produced a definite improvement, but if the dose was reduced below 100 mg daily she had severe asthmatic attacks She developed a moon-face and mild hypertension of 135/90 mm Hg After 6 months the cortisone was replaced by prednisolone, initially 20 mg daily, but it was possible to reduce this to 10 mg daily over a period of 7 months without precipitating asthma During this period she grew 3 in taller, gained 12 lb in weight, and developed a good physique Her blood-pressure fell to 125/80, but her facial rounding remained She also developed acne and hirsutism, and noticed that her clitoris was enlarging

Prednisolone was replaced by triamcinolone, and on a daily dose of 4 mg she remained free of serious asthma for 4 weeks, but after 5 or 6 days she began to develop severe pains in her arms and legs, and noticed that her fingers were becoming stiff

Her right leg was particularly painful and examination revealed a tender nodule in the lateral head of the gastrocnemius. Her fingers showed swelling of the proximal and middle phalangeal joints, and the movements of her wrists, elbows, shoulders, hips, and knees were all limited by pain.

The triamcinolone was stopped and she was again given prednisolone 10 mg daily. The joint pains and stiffness disappeared in 2 days and a week later her fingers were normal.

Case 3.—An Indian woman, aged 21, had a 5-year history of bronchial asthma. This was controlled by cortisone 100 mg daily, but, during 7 months' holiday in India, her weight increased from 103 lb to 164 lb (height 63 in.) and she developed a very pronounced moon-face, slight dependent œdema, and a blood-pressure of 130/90 mm Hg. On a slimming regime and replacement of cortisone by prednisolone 10 mg daily, she slowly lost weight, her face became thinner, and her blood-pressure fell to 120/80. Her asthma was controlled by this dose, but she developed severe acne and hirsutism. Another complication was a vulval abscess, which responded to penicillin. It was found that her clitoris was unusually large.

Prednisolone was replaced by triamcinolone, and on a daily dose of 4 mg she remained free of asthma for 7 weeks. After 5 weeks, however, she complained that her legs seemed weak and she had pain in her knees. No objective evidence of arthritis was found, but, when the triamcinolone was stopped and she started on prednisolone again, the pain and weakness ceased.

Discussion

The onset of arthritic symptoms in three out of nine patients (who had no previous history of arthritis) when treated with triamcinolone instead of prednisolone strongly suggests that the change of therapy was responsible. The first two patients developed the typical appearances of early rheumatoid arthritis, and no other predisposing cause, such as infection or climatic change, was evident. All three were young women whose previous prednisolone therapy had produced virilising side-effects, and this may be significant. Two other women showing these side-effects, one with advanced rheumatoid arthritis and the other with systemic lupus erythematosus, had severe exacerbations of their joint symptoms when given triamcinolone, but this might have been merely due to inadequate dosage with corticosteroids, which often produces such relapses.

Possibly the arthritic symptoms in these three patients were primarily the result of prednisolone withdrawal. This seems unlikely since the use of prednisolone in many conditions in Singapore has not precipitated such symptoms, unless the patients had arthritis before the initial administration of corticosteroids. The remaining possibility is that triamcinolone directly caused an arthritic syndrome resembling, if not identical with, rheumatoid arthritis. It would be interesting to give the three patients another course of triamcinolone, to see whether they again develop arthritis, but they have not agreed to such a trial, and this unexpected finding must await further confirmation before its true significance can be assessed.

Apart from the development of arthritis, the results of triamcinolone therapy in this small series of patients were highly promising. In some cases its therapeutic efficiency was superior to that of prednisolone. The potency of triamcinolone was usually greater than that of prednisolone, though there was considerable variation in the equivalent dosages of the two corticosteroids in different patients.

Summary

Fourteen patients, previously maintained on prednisolone therapy for various conditions, were given triamcinolone. Of nine with no previous history of joint symptoms, three developed arthritis, and their histories are reported.

In two patients the condition resembled acute rheumatoid arthritis. It is suggested that arthritis may be a side-effect of triamcinolone therapy.

I am grateful to the Lederle Laboratories Division of the American Cyanamid Company for providing the triamcinolone ('Ledercort').

SLIPPING OF THE UPPER FEMORAL EPIPHYSIS

A PLEA FOR URGENCY

P. H. NEWMAN
D.S.O., M.C., F.R.C.S.

ORTHOPÆDIC SURGEON, THE MIDDLESEX HOSPITAL AND ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, LONDON, W.1

UNTIL recently the standard treatment of slipping of the upper femoral epiphysis was often traction in bed for six months or more. This gave relief from weightbearing, but in a large proportion of patients it did not achieve reduction. In a few cases the deformity even increased. In addition, at the end of this period the limbs were so weak, and sometimes so stiff, that they could ill support a heavy child whose weight had not decreased while lying in bed. Fusion across the epiphyseal line had been accelerated, but only at the expense of strength and function.

Surgical Treatment

Before 1929 this condition had frequently been treated by manipulation and plaster immobilisation, but a paper by Carnitz, which showed the results of manipulation, brought a sharp change in policy.

In 1938 Wilson, of the Hospital for Special Surgery, New York, described good results in 9 cases in which a Smith-Petersen pin had been inserted across the epiphyseal line. This operation produced equally good results in other clinics, so that internal fixation became accepted as a standard treatment for minor degrees of slip. The method has the limitation that it cannot be used when the displacement exceeds one-third of the maximum, but, with this proviso, it is a valuable procedure. It immediately stabilises the epiphysis, it prevents further slipping, and it accelerates fusion at a favourable age and at a level where interference with limb length is not serious.

With proper technique the operation is simple to perform and the patient has to be immobilised for no longer than it takes the wound to heal. A child can return to school after three weeks. More recently Smith-Petersen's trifin nail has been criticised as being unnecessarily large and traumatic and Hall (1957) has shown that smaller pins are equally effective and less likely to damage the vessels of the upper end of the femur.

Once the epiphysis has become dislodged, it is liable to go on slipping. Minor slips can be dealt with easily and satisfactorily, but major ones, if irreducible, have a very different prognosis. Left alone, these hips develop an adduction and external-rotation deformity, their range of movement will diminish, and there will be shortening and

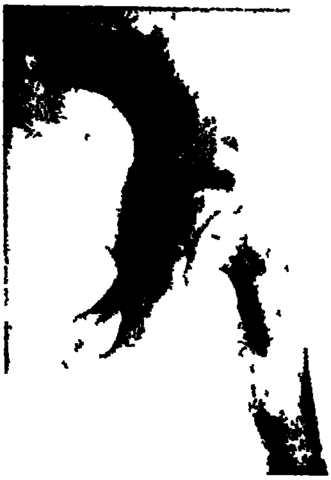

Fig 1—Severe, irreducible deformity

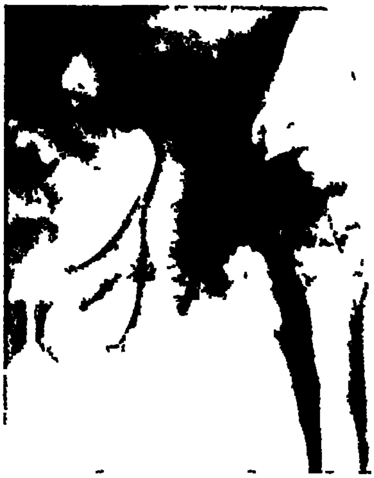

Fig 2—Osteoarthritic changes of untreated adolescent coxa vara

liability to premature osteoarthritis (figs 1 and 2) To such inactive treatment surgery is the only alternative but none of the operations employed is uniformly satisfactory

Groups of Patients

In the first group are adolescents with minor slips They should be regarded as surgical emergencies Immediately the condition is diagnosed the patient must cease to bear weight, and the surgeon must not rest content until the epiphysis is safely stabilised by pinning Once this has been done, it may be justifiable to assume that the hip-joint has been saved

Patients with acute traumatic displacement comprise the second group They should be treated by immediate reduction and simple pinning Provided that treatment is started while the epiphysis is still mobile, replacement is not difficult A difficult manœuvre—where force has to be used—is liable to damage further the already precarious blood-supply, and this may lead to stiffening Reduction is obtained by traction in internal rotation for two or three days, followed by gentle replacement under a general anæsthetic

The third group of patients are those who have a severe, irreducible deformity They all started in the first or second group but they were either not recognised or not treated in time

Causes of Delay

It was the long interval between the onset of symptoms and the beginning of surgical treatment which prompted me to refer to the notes of 45 cases treated under my care during the past ten years From this review two significant facts emerged. The average time between the onset of symptoms and the diagnosis was 26 6 weeks The average time between diagnosis and admission for definitive treatment was 3 8 weeks (This second figure includes the time spent by some patients undergoing treatment by bed rest and traction before their transfer to an orthopædic unit for pinning)

The causes of the delay were as follows

1 Failure of the patient to recognise and report symptoms

2 Failure of parents, schoolteachers, or games staff to recognise and report symptoms

3 Delay in clinical diagnosis

4 False radiological reassurance

5 Lack of realisation of the urgency of treatment by the referring doctor, or by the hospital clerical or surgical staff

It is unlikely that anything can be done to shorten the delay which is due to the adolescent not reporting his symptoms They are often slight, and his attitude is understandable, even admirable Failure of the parents or of the school staff to appreciate the significance of such symptoms is also understandable the condition is so uncommon and so difficult to recognise that it would be inappropriate to burden the public with medical propaganda for wider recognition It is unfortunate that by far the greatest delay occurs for these two reasons

Delay in Clinical Diagnosis

Even to the clinician, however, slipping of the epiphysis may be a difficult diagnosis It affects two types of patients, the fat type with hypogonadism and the long-limbed type who is passing through a phase of rapid growth It is slightly more common in boys In girls the commonest age of onset is twelve, and in boys thirteen, but the trouble may start at any time between nine and cessation of growth

The symptoms are invariably pain, a limp, or both The pain is sometimes localised to the hip, but more often it is referred to the lower anterior part of the thigh, or to the knee There is generally no other complaint and the patient may have continued to play games, however strenuous Examination of the hip will show limitation of abduction, of flexion, and of internal rotation, depending on the degree and the direction of the slip

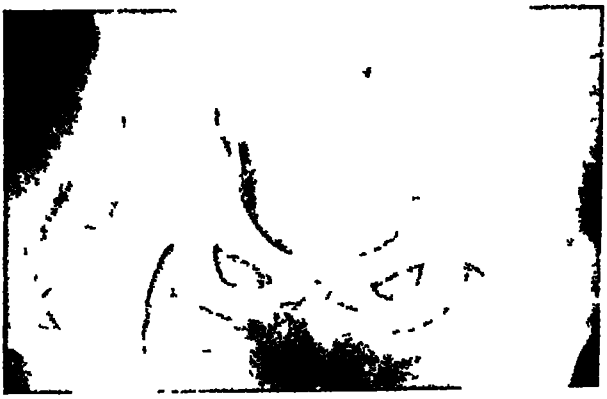

Fig 3—Anteroposterior view of hips, showing very little evidence of slip on right side

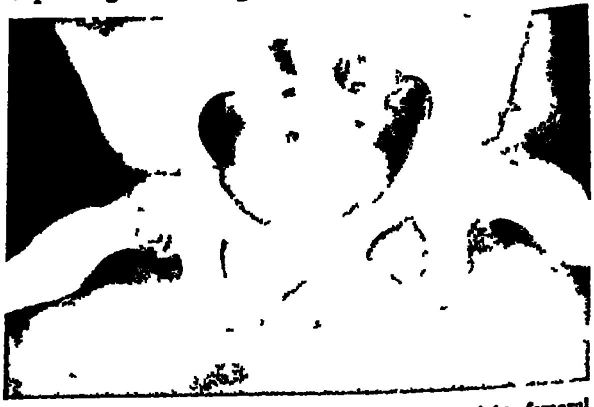

Fig 4—Same case, showing undoubted slip of right femoral epiphysis

Fig 5—Epiphysis stabilised by pinning

In severe cases there will be considerable flexion, adduction, and external-rotation deformity with true and apparent shortening The great trochanter will be displaced towards the pelvis It is rational to submit any child or adolescent who complains of pain in the hip or knee to X-ray examination of the hip-joints

Delay in Radiological Diagnosis

In a surprising number of cases referred for X-ray examination normal results are returned In this series such false radiological reassurance was the cause of delay in 7 cases Omission to take a lateral view was the reason for the mistake Often an anteroposterior view will show very little abnormality, whereas a lateral view will clearly demonstrate early slipping (figs 3–5)

The Urgency

Even when the condition is suspected or diagnosed, the urgency of treatment is often not recognised There may be delay in referring the patient to the appropriate clinic, or a distant appointment may be accepted by the practitioner or by the receiving-room or clinical staff

Slipping of the upper femoral epiphysis should be recognised as a surgical emergency, and admission to hospital should be immediate Modern operative treatment gives excellent results in early and acute traumatic cases, often necessitating a stay in hospital of no longer than three weeks Delay makes the prognosis much worse

THE SYNDROME OF THE SUSPENDED HEART

BERTRAM A BRADLOW
M.D W'srand, M.R C.P, M R C.P E
MONTY M ZION
M B W'srand, M R C.P
From Johannesburg General Hospital and the University of the Witwatersrand

THE occasional finding of abnormal electrocardiograms in patients without manifest cardiac disease may cause much difficulty in assessment of these subjects Without necropsy evidence of a strictly normal myocardium one cannot with assurance state that the electrocardiographic disturbance is not associated with heart-disease However, Evans and Lloyd-Thomas (1957) have, under the title of "The syndrome of the suspended heart," presented convincing evidence of the association of certain specific electrocardiographic "abnormalities" with a particular radiological configuration of the heart. Briefly, the electrocardiograms show abnormal S-T segments and T waves suggesting infarction of the lateral and postero-inferior portions of the left ventricle, or of left ventricular strain without abnormal voltages Radiological examination shows a heart that, during deep inspiration, appears to be suspended between the vascular pedicle above and the inferior vena cava below

We report here three cases of this syndrome seen by us in private practice since the publication of the article by Evans and Lloyd-Thomas (1957)

Case-reports

Case 1.—A girl, aged 12 years, was referred because of persistent headaches and abdominal pain, with failure to gain weight steadily Her past history was insignificant

On examination she was of ectomorphic build and 4 ft 11 in tall and weighed 67 lb Her blood-pressure was 110 60 mm. Hg and cardiac impulse normal A grade I early systolic murmur was present at the apex and along the left parasternal area A third heart sound was heard at the apex The remainder of the physical examination was irrelevant The urine contained albumin, but repeated examinations showed orthostatic albuminuria A full blood count and the erythrocyte-sedimentation rate were normal The urine contained no abnormalities on microscopy and was sterile on culture The blood-urea level was 20 mg per 100 ml A chest radiograph (fig 1) showed a long thin heart which, on deep inspiration, appeared to be lifted off the diaphragm and suspended by the vascular pedicle

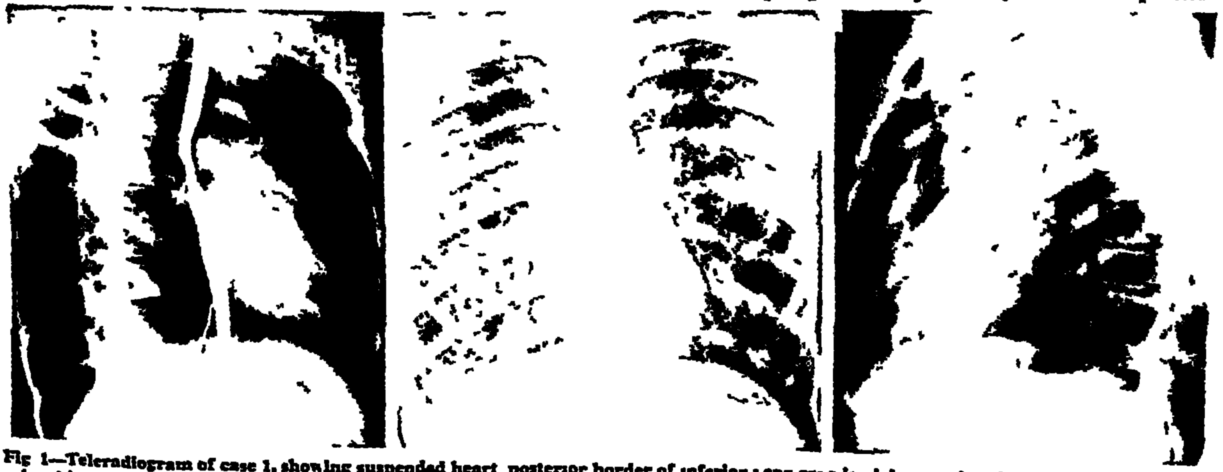

Fig 1—Teleradiogram of case 1, showing suspended heart, posterior border of inferior vena cava in right anterior oblique view is outlined in white

Dr. Robert [illegible] Library

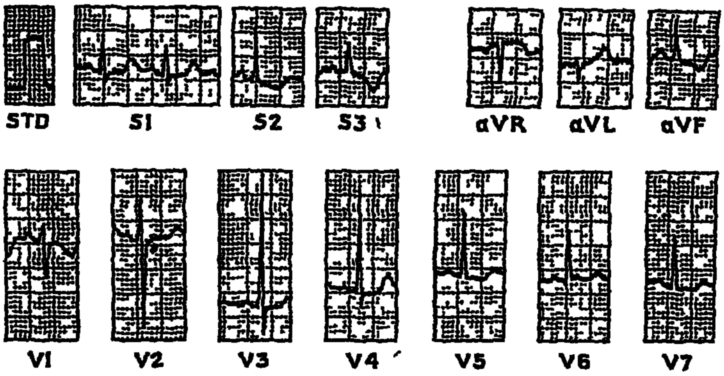

Fig 2—Electrocardiogram of case 1

and the inferior vena cava Electrocardiography showed depressed S-T segments in leads II, III, aVF, V5, V6, and V7, with inverted T waves in III and aVF (fig 2) V6 recorded one interspace higher showed smaller changes, and the abnormality was diminished but not obliterated by squatting The tracing was not altered by lying prone or by Valsalva's manœuvre

Case 2—A married woman, aged 24, had persistent gnawing pains under her left breast, unrelated to exertion She often felt breathless, both at rest and on exertion, and she tended to sigh frequently She was troubled by pins-and-needles in her hands Her past history was not significant

On examination she was of mesomorphic build and 5 ft 6$^1/_2$ in tall and weighed 141 lb She had congenital ichthyosis of the skin of the trunk and limbs Her blood-pressure was 120/70 mm Hg No abnormalities were detected in her heart or elsewhere Nothing abnormal was found in her urine Radiography of her chest (fig 3) showed a rather globular heart which, in the oblique views, rose high off the diaphragm during inspiration, throwing the inferior vena caval shadow into prominence Electrocardiography showed inverted T waves in leads II, III, aVF, V4, V5, V6 and CR4 (fig 4) These changes were less after effort The picture was not altered by sitting, lying prone, standing, squatting, or the Valsalva manœuvre Electrocardiography repeated two months later showed no change

Case 3—A man, aged 41, had been rejected for military service at the age of 18 because of possible rheumatic heart-disease In 1936, at the age of 20, he consulted a physician, but no clinical abnormality was found, although the electrocardiogram (fig 5) showed flattening of the T wave in lead II, and inversion of the T wave in lead III, with pronounced right axis deviation Since that time he has remained perfectly well and symptom-free Repeated physical examinations between 1955 and 1957 have shown no cardiac abnormalities A third heart sound and a grade-I systolic murmur were audible at the apex in 1955, but in 1957 the murmur was absent and the third sound was soft and inconstant These auscultatory findings were confirmed by phonocardiography

On examination he had a slightly depressed sternum, but the remainder of the physical examination was normal He was of mesomorphic build and 5 ft 7$^1/_2$ in tall and weighed 176 lb His blood pressure varied from 130 to 150 systolic and 80 to 90 diastolic A ballistocardiograph* in 1955 was interpreted as normal The electrocardiogram (fig 6), which has remained unchanged since 1955, revealed flattening of the T waves in lead II, with inversion in leads III, aVF, and V6 The degree of right axis deviation was much less than in 1936 The T-wave abnormality disappeared after effort or if the patient was placed in the sitting position with his legs horizontal Placing the electrode one interspace higher for V6 also produced a normal T wave The electrocardiogram was not altered by lying prone, standing, or the Valsalva manœuvre A chest radiograph (fig 7) showed a heart lifted well off the diaphragm, with prominence of the shadow of the inferior vena cava

Discussion

If the electrocardiograms discussed by Evans and Lloyd-Thomas (1957) are normal and associated with a peculiar stance of the heart within the thorax, it might be expected that the changes might be found even in children, as in the present case 1 The true incidence of this syndrome in a population cannot be known without mass surveys, but the recognition of the benign nature of the electrocardiographic findings is important, for the sake of reassurance of the patient and for the question of insurance

Case 2 indicates that the degree of electrocardiographic "abnormality" may be considerable However, the response to effort, as mentioned by Evans and Lloyd-Thomas (1957), helps to differentiate the changes from those due to coronary-artery disease

Evans and Lloyd-Thomas (1957) write:

> "The separation of the suspended heart from its close contiguity with its surrounding structures, particularly the diaphragm, disturbs the anatomical medium that customarily transmits the varying electrical potential generated by cardiac contraction, and this we consider gives rise to changes associated with this characteristic cardiogram"

If their theory is correct, it is to be expected that, in some cases, posturing of the patient might alter the anatomical relationship of the heart to its environs In

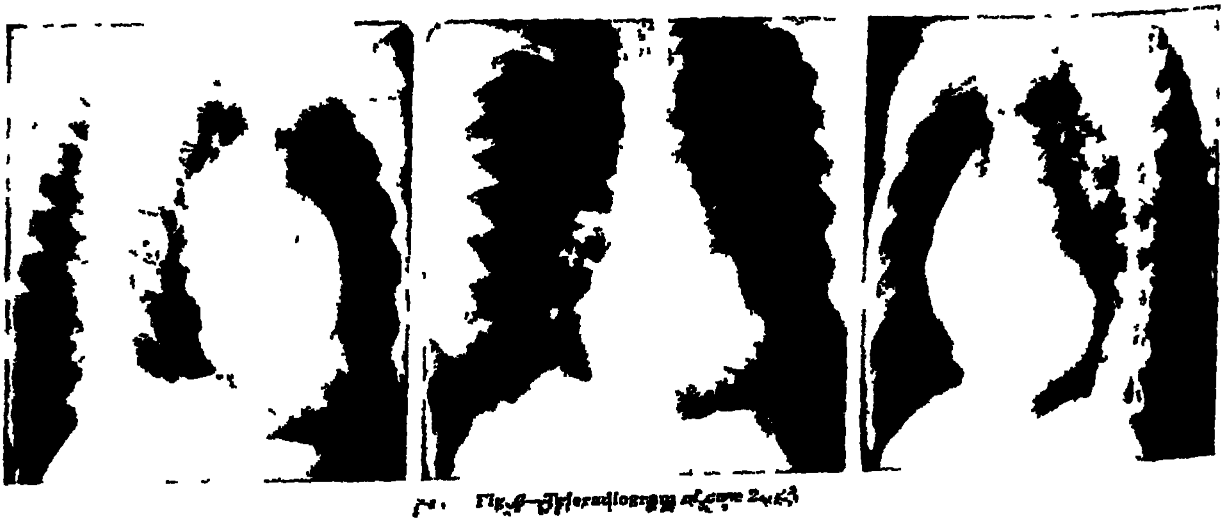

Fig 3—Teleradiogram of case 2

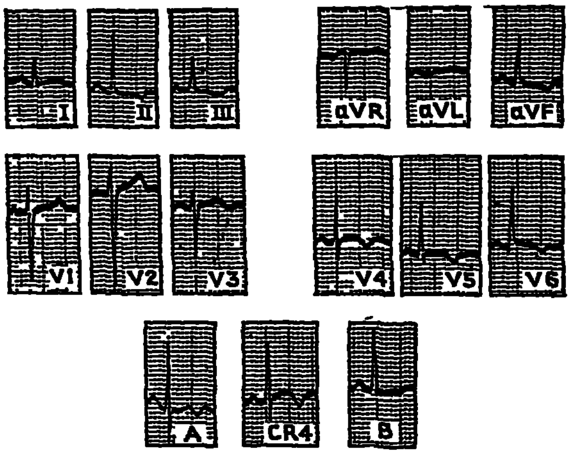

Fig 4—Electrocardiogram of case 2 A, CR4 recorded after effort, B, lead II recorded after effort

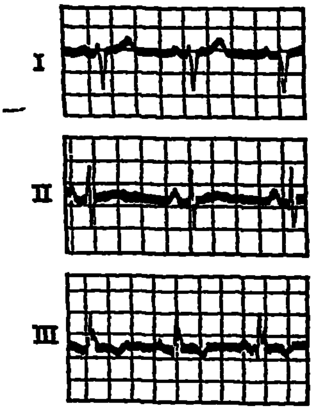

Fig 5—Electrocardiogram of case 3 in 1936

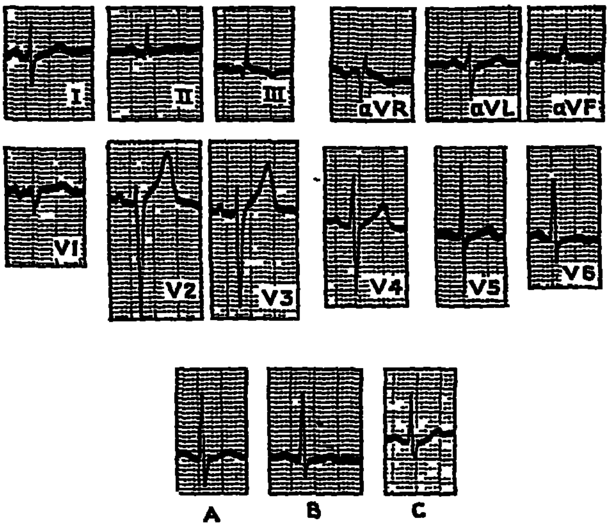

Fig 6—Electrocardiogram of case 3 A, V6 recorded with patient sitting, B, V6 recorded one intercostal space higher than normal, C, V6 recorded after effort.

case 3, with the patient in the sitting position with his legs horizontal, the T wave, previously inverted, became upright In case 1 squatting diminished the degree of abnormality

It therefore seems that the relationship of the heart to its environment, particularly the diaphragm, may be the factor concerned in causing the electrocardiographic "abnormality" Whether this is due to disturbance of the transmission of electrical potential, as stated by Evans and Lloyd-Thomas, or to an alteration of the direction of the repolarisation vector, as seems more probable to us, remains a matter for conjecture If an electrode could be placed directly on the heart in such a person, the mechanism might be further elucidated

As Evans and Lloyd-Thomas have done, we also have seen patients with similar radiological appearances of their hearts but with normal electrocardiograms We have not been able to confirm their observations that closer scrutiny of these radiographs shows more of the heart shadow in contact with the diaphragm than in those subjects with the "abnormal" electrocardiograms However, we do not deny the possibility that, in those with normal electrocardiograms, the anatomical relationships of the heart may be different from those of persons with the "abnormal" electrocardiograms discussed above

Summary and Conclusions

Three further cases of the "syndrome of the suspended heart", as described by Evans and Lloyd-Thomas (1957), are reported, one being in a child aged 12 years There is an association of a characteristic radiological picture of a heart lifted off the diaphragm and suspended between the vascular pedicle and the inferior vena cava, with an electrocardiogram showing S-T and T changes in posterolateral leads The benign nature of the syndrome is confirmed, and the abnormal changes are demonstrated in unipolar chest leads, in contrast to the bipolar chest leads used by Evans and Lloyd-Thomas

We thank Dr M M Suzman for the loan of the electrocardiogram of 1936 in case 3, and Mr A M Shevitz for the reproductions of the radiographs and electrocardiograms

POSTOPERATIVE MALABSORPTION
SECONDARY PROTEIN MALNUTRITION SYNDROME

Z A Leitner
M D Berlin, L R C P E

The considerable literature on the malabsorption syndrome has been competently reviewed by Adlersberg (1957) and Volwiler (1957) in the United States, and different aspects of postoperative malabsorption have been discussed by Brain (1951, 1953, 1954), Welbourn and Doggart (1956), and Welbourn et al (1956) in this country The greater part of the relevant literature deals with steatorrhœa, electrolytes, hæmatological or vitamin deficiencies, and osseous changes There are few references to the malabsorption of proteins

A patient with " intractable avitaminosis " in a London hospital proved to have postoperative nutritional failure (protein malnutrition, secondary kwashiorkor) As I could not find a single similar published case I circulated the case-history widely, only to be informed that no such condition has ever been seen in a number of large gastroenterological departments (Dr W I Card, Dr F Avery Jones, Mr Rodney Smith, and Mr N C Tanner, personal communications) However, scrutinising Mr Rupert Corbett's postoperative material I found another patient in London who showed repeatedly the fully developed syndrome of protein malnutrition Publication of these cases may lead to the recognition and study of others

Case-reports

THE FIRST CASE

This was demonstrated briefly at a meeting of the Nutrition Society last December (Leitner 1958)

A man, aged 61, was admitted to a London Hospital in July, 1953, with four days' history of upper abdominal pain radiating into his left shoulder and arm, vomiting, and severe jaundice His serum-bilirubin level was 10 mg per 100 ml, thymol turbidity 2 units, alkaline-phosphatase 120 King-Armstrong units, Hb 13 5 g per 100 ml, and white cells 22,400 per c mm (polymorphs 84%) At operation on Aug 6, 1953, a hard mass felt in the head of his pancreas was thought to be a carcinoma, but histological examination later showed only chronic pancreatitis A partial gastrectomy was done, with resection of the head of the pancreas and choledochoenterostomy with insertion of the pancreatic duct into the duodenum After operation he temporarily lost weight

Course of Illness

June, 1955—He felt ill and was admitted for reassessment The findings were Hb 12 1 g, all pancreatic enzymes absent, total fæcal fat 36 3 g per 100 g of dried fæces, serum-protein 4 7 g per 100 ml (albumin 2 5 g, globulin 2 2 g) A high-protein low-fat diet was given, with large doses of pancreatin, vitamins, and iron, and after four weeks the patient was discharged greatly improved, with serum-protein 5 8 g per 100 ml

January, 1956—Readmitted He was passing three or four bulky motions daily, had lost weight, and had swelling and ulceration of his legs The findings were Hb 12 2 g, blood-sugar 102 mg per 100 ml, serum-proteins 4 3 g, serum-bilirubin 0 9 g, thymol turbidity 4 units, and alkaline phosphatase 18 units A high-protein low-fat diet was again given, with pancreatin, iron, and vitamins, and three weeks later his condition improved and he was discharged

May, 1956—Readmitted complaining of severe pain in his legs and of general malaise, he had œdema of his ankles, punctate pink spots with petechial striæ across his ankles and lower legs, and shallow trophic ulcers scattered all over his body, but mainly on his face and head It was then thought that he was having neither sufficient nor the right type of care and diet at home In hospital the purpuric striæ had spread up his legs to his thighs and rump, and a brown pigmentation, which appeared first on his legs, extended towards his trunk Meanwhile the purpuric staining had involved the whole of his trunk and become more noticeable in the pressure areas He had no bleeding from his gums Large doses of vitamins were given orally, and parenterally, but the skin eruption, which was thought to be due to a deficiency of vitamins B and C, further exfoliated

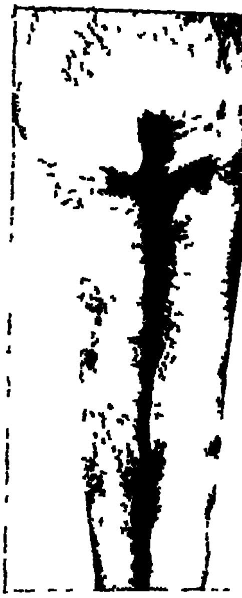

Fig 1—Mosaic-like crazy pavement dermatosis, with dry wrinkled xerotic skin between lesions and cracks in hyperpigmented areas

May 19, 1956—Hb 11 1 g per 100 ml, serum-proteins 3 5 g per 100 ml (albumin 1 3 g, globulin 2 2 g per 100 ml)

May 25, 1956—Blood-sugar tolerance fasting 93 mg per 100 ml, half-hourly figures 119, 150, 190, 193, 170 mg per 100 ml, with some excretion of sugar shown in the last two specimens

June 21, 1956—Serum-proteins 3 8 g (albumin 1 8 g, globulin 2 0 g)

Aug 3, 1956—Serum-proteins 3 6 g (albumin 1 5 g, globulin 2 1 g)

Aug 8, 1956—Intravenous ascorbic-acid test yielded in the urine only 21 mg of the expected 200 mg, blood-pyruvic acid 3 4 mg per 100 ml (normal values 0 1–1 0 mg, in marked thiamine deficiency up to 2 0 or 3 0 mg) 4 pints of plasma, followed by a litre of hydrolysed protein, together with massive doses of vitamin-B complex and vitamin C, was administered subsequently There was transitory improvement (on Aug 13 the serum-protein level was 5 2 g), but the patient relapsed within a week, and new pink spots and striæ and new ulcers appeared

Aug 22, 1956—I saw the patient in consultation at the hospital He was apathetic, wasted, and obviously ill, with moderate œdema of his ankles and sacrum, and answered questions mechanically I found no abnormality apart from sluggish tendon-reflexes Extensive pigmented pellagra-like dermatosis covered the greater part of his body, but places exposed to light were free from such lesions The skin in

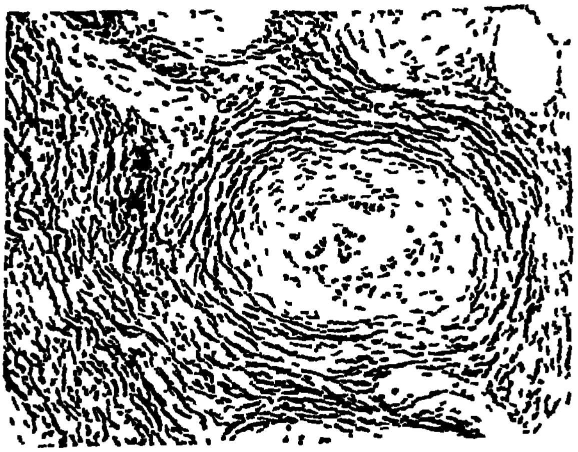

Fig 2—Dilatation of pancreatic duct, with severe periductal fibrosis, fibrous replacement of parenchyma and complete absence of acinar tissue (× 130)

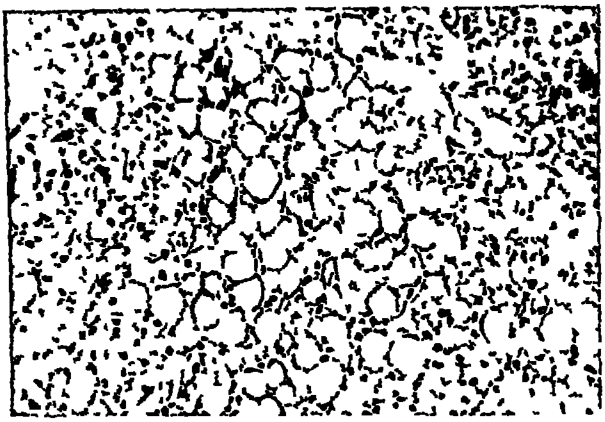

Fig 3—Very severe fatty change in liver (× 90)

between the lesions was dry, wrinkled, and in places scaly and xerotic, with exfoliation, giving the general impression of crazy-pavement or mosaic-like dermatosis There were numerous cracks, mainly in the hyperpigmented areas (fig 1) Scattered all over, but mainly on his legs and back, were punctate purpura-like spots and striæ, with pinkish pigmentation, at first sight similar to, but on examination quite different from, the perifollicular hæmorrhages of scurvy No changes were found in the mucosæ, mucocutaneous junctions, or conjunctivæ A sample of blood contained carotenoids 5 I U , vitamin A 56 I U , and vitamin E 0 14 mg per 100 ml

Aug 29, 1956—Prothrombin time 20 sec (normal control 15 sec), serum-calcium 8 6 mg per 100 ml , inorganic phosphorus 4 2 mg per 100 ml

Sept 6, 1956—Serum-proteins 3 8 g per 100 ml (albumin 2 1 g , globulin 1 7 g) Hb fell to 9 5 g He died on Sept 9

Necropsy

Brain œdema of white matter, slight atheroma of arteries at base *Heart* brown atrophy of myocardium *Vessels* slight atheroma of coronary arteries and aorta *Lungs* serous pleural effusions, 2 pints *Peritoneum* serous ascites 1 pint *Liver* very severe fatty change (floats in water), gallbladder distended and lined by smooth grey mucosa, old anastomosis between common bileduct and duodenum, with dilatation of common bileduct *Stomach* pyloric portion resected, old gastrojejunal anastomosis (intact), duodenal stump intact, adhesions between loops of upper jejunum in right hypochondrium but no evidence of side-to-side anastomosis *Pancreas* head removed, fibrosis of remaining body and tail, with dilatation of pancreatic duct (containing mucus), no communication between pancreatic duct and duodenum *Spleen* congested *Kidneys* cloudy swelling *Suprarenals* atrophied lipoid layer in cortex. *Bone-marrow* pink hæmopoietic marrow (floats) in neck and upper third of femoral shaft *Analysis of the liver* showed a fat content of 32 4% and vitamin-A content of 120 I U per g of fixed liver

Histological Report

Pancreas hypertrophy of islet tissue, complete atrophy of parenchyma, with chronic inflammation and fibrous replacement, and gross dilatation of duct (fig 2) Slight chronic inflammation and fibrosis of portal tracts of liver with proliferation of bile canaliculi and extreme fatty change (fig 3) Chronic inflammation of gastric mucosa Severe congestion and chronic inflammation of spleen Congestion, cloudy swelling, and ischæmic changes in *kidney* Atrophy of *epidermis*, with scattered focal deposits of blood pigment in fibrotic dermis of skin from medial side of left leg Focal atrophy of voluntary muscle-fibres and endoneural fibrosis of small nerve-bundles in dermis and subcutaneous tissue

THE SECOND CASE

A married woman, aged 59, was admitted to St Bartholomew's Hospital on Aug 31, 1950, having lost 2–3 st of weight during the preceding year, and developed anorexia, vomiting, and malaise, just before admission she became jaundiced In hospital a complete duodenal obstruction developed On Sept 5 pancreatico-duodenectomy (gastrojejunostomy, cholecystogastrostomy, resection of the head of the pancreas) was performed, and a large neoplasm was removed which completely filled the second part of the duodenum, encircling the common duct and papilla The growth was of primary duodenal origin, the head of the pancreas and the lymph-nodes not being infiltrated Recovery was uneventful, and she was discharged on Nov 1 on pancreatin and iron

First Readmission (Jan 28, 1952)

After being well for about a year, she developed steatorrhœa and lost weight in spite of her large appetite Her face was puffy, and œdema extended almost to both knees She had dry exfoliative dermatitis, a smooth red tongue, cheilosis, and angular stomatitis Her serum-protein level was 3 8 g per 100 ml (albumin 2 0 g , globulin 1 8 g) Her fæces contained fat-globules and undigested muscle-fibres Total fæcal fat 45 1% (10 8% unsplit) Hb 12 4 g per 100 ml White cells 4700 per c mm (differential count normal) Nitrogen balance negative over four days (5 3 g of N excreted daily) Of an average daily intake of 46 g fat (four days) she excreted 26 g in the stools She was given protein-rich fat-poor diet with 'Casydrol', 30 g of proteolised liver extract daily, and vitamin-B complex parenterally Feb 22 total proteins 3 8 g (albumin 1 8 g , globulin 2 0 g) March 5 total proteins 4 2 g (albumin and globulin each 2 1 g), œdema was still present, therefore 100 g of predigested protein ('Pronutrin') was given daily March 13 total proteins 5 1 g (albumin 2 8 g , globulin 2 3 g) March 28 total proteins 6 7 g (albumin 3 4 g , globulin 3 3 g) She was discharged on March 28, 1952, clinically recovered She had normal formed stools Her œdema and exfoliative dermatitis had disappeared

Second Readmission (Jan 30, 1953)

During the last two months increasing flatulence, anorexia, sweating of her face and neck when eating "she went to pieces" Pain radiated into her left shoulder and axilla Puffiness of the face, gross swelling of her legs, considerable sacral œdema, Smooth red denuded tongue in spite of injections of vitamin-B complex by her doctor, bilateral pleural effusion, generalised osteoporosis Hb 11 8 g , white cells 8000 (differential count normal) Total serum-proteins 3 2 g (albumin 1 7 g , globulin 1 5 g) Treatment high-protein low-fat diet, vitamins, iron, pancreatin, daily infusion of 25 g of dried serum-albumin in 5% glucose Feb 20 total proteins 5 1 g (albumin 2 8 g , globulin 2 3 g) Feb 25 total proteins 5 8 g (albumin 3 05 g , globulin 2 75 g), pyruvic-acid-tolerance curve normal (fasting 0 75 mg of pyruvic acid per 100 ml , 1 34 mg per 100 ml 1 hour after 50 g of glucose) Feb 27 discharged feeling well, œdema and pleural effusion had disappeared

Follow-up

During 1953–57 the patient was regularly followed up by Mr Corbett with the assistance of Dr E F Scowen She ate, felt and looked well, and kept her weight steady Hb on Oct 5, 1956, was 15 4 g I examined her with Mr Corbett on May 24, 1957 Clinically she was well Total proteins were 6 0 g (albumin 4 0 g , globulin 2 0 g), Hb 14 2 g She reported that every day she ate a meat or a fish meal, usually one or two eggs, and a pint of milk reinforced with casylan She had taken pancreatin continuously and had intermittent courses of vitamin-B complex In spite of this she had occasionally a smooth tongue, with mild cheilosis and angular stomatitis

Third Readmission

On Sept 18, 1957, she was readmitted under Dr Scowen She felt well, apart from sweating of her face after eating, but had become worried about herself On clinical examination nothing abnormal was found Investigations showed blood-pressure 135/80 mm Hg, Hb 14 5 g per 100 ml , mean corpuscular volume 84 cμ , blood-urea 32 mg per 100 ml , serum-proteins 5 3 g per 100 ml (albumin 3 5 g , globulin 1 8 g), with normal electrophoretic pattern, thymol turbidity 3 units, total serum-bilirubin 0 5 mg per 100 ml , direct negative, serum sodium 141, potassium 5, chlorides 111, alkaline reserve 25 mEq per litre, serum-calcium 8 8 mg per 100 ml , inorganic phosphorus 3 7 mg per 100 ml , alkaline phosphatase 12 King-Armstrong units Glucose-tolerance test fasting 118, half-hourly figures 205, 220, 162, 128, 136, and 118 mg per 100 ml Fæces undigested muscle-fibres and fatty-acid crystals, total fat 30% of the dry matter Radiography lungs normal, spine, pelvis, and hands showed diffuse osteoporosis

Discussion

In case 1 the provisional diagnosis of an intractable vitamin-deficiency state was supported by the symptoms and signs and the biochemical data My colleague, Dr T Moore, commenting on the exceedingly low level of carotenoids and vitamin E, reminded me of his similar findings in kwashiorkor (Trowell et al 1954a and b) Brock (1955) also has emphasised that the clinical appearances of kwashiorkor may be modified by the complicating deficiencies of vitamins During the consultation in case 1 the diagnosis of severe avitaminosis was extended to that of nutritional failure, and it soon became evident that the main underlying cause was protein malnutrition Although, because of the patient's death, further investigations could not be made, the diagnosis was confirmed by the low serum-protein level (3 8 g per 100 ml or less) which persisted for several months with inverted albumin/globulin ratio, and subsequently by the necropsy findings These serum-protein levels, like those in case 2 during the first and second readmissions (3 8 and 3 2 g per 100 ml respectively), were substantially lower than those published in large series of kwashiorkor (Dean and Schwartz 1953, Kinnear and Pretorius 1956)

Dermatological lesions are not obligatory signs of protein malnutrition but they do develop in different parts of the world in 25–80% of the cases, and then they always appear on parts of the body not exposed to light Dryness, scaling, and wrinkling of the skin are always present, often with xerosis and pigmentation, with or without mosaic, crazy-pavement, or enamel-paint-like dermatosis According to Gopalan (1955) in India it often starts with pinkish punctate discoloration, mainly on the anterolateral aspect of the legs, as in case 1 This has also been observed in Kampala and other places (Trowell et al 1954a) Although, sometimes a prolongation of the prothrombin-time has been reported in association with these punctate purpura-like spots, neither in case 1 nor in the cases described in Tunis (Caruana et al 1953) was the prothrombin-time prolonged In the Tunisian cases the red spots could not be prevented by treatment with vitamin C and vitamin K

In protein malnutrition the skin lesions always quickly disappear on a high-protein diet, as in case 2 during the first readmission, but neither diet nor plasma infusions had the slightest influence on the exfoliative dermatosis extending over two-thirds of the body's surface in case 1 The serum-protein levels were lower and the clinical symptoms and signs were much more severe in case 2 during the second readmission In spite of this no dermatological lesions developed as on admission a year earlier

The protein-malnutrition syndrome is much less common in adults than in children (Trowell et al 1954a), and the extent and the severity of the skin lesions seem to bear no direct relation to the severity of the disease (Rao 1955) Signs of the syndrome, with typical though limited dermatosis, were described in two Polish refugee women, aged 25 and 40, who suffered great privations during migration through Russia and the Middle East until they reached Uganda (Brown and Trowell 1944), but I am aware only of two other cases of this syndrome ever described in a white man A Dutch seaman recovered completely on treatment for a year with pancreatin, choline, and a protein-rich diet (Van Steenis 1950) A South African male, aged 40, was dramatically cured after correction of a 6 ft blind loop surgically constructed 3 ft proximal to the ileocæcal valve (Kritzler and Schrire 1958)

It was impressive how quickly the clinical condition and the serum-protein level reacted in both patients (in case 1 only during the first two readmissions) to simple dietetic measures reinforced by pancreatin and vitamins Unfortunately we have so far no means of defining protein malnutrition exactly, because we cannot estimate the protein content of the body or assess even approximately the extent of the body's stores of protein We therefore had to be satisfied with estimating the total serum-proteins, and this, together with the estimation of the protein fractions, seemed to be a surprisingly accurate guide so far as the fluctuation of the clinical condition was concerned This was recently emphasised also by Waterlow (1956) We found, however, some difficulty in explaining the comparatively sudden fall and sudden rise of serum-protein levels Both these patients made a spectacular recovery within three to eight weeks with the help of only dietetic measures during their first readmission Thus the serum-protein level in case 1 rose from 4 7 to 5 8 g per 100 ml and in case 2 from 3 8 to 6 7 g per 100 ml It therefore appears that the low serum-protein levels were due in both cases to comparatively sudden onset of malabsorption

Increased fæcal excretion of fat (Gordon-Taylor et al 1929) and considerable loss of weight (Maclean et al 1954) have been known for some time to follow gastric operations, even when the secretion of pancreatic enzymes is normal Resection of the head of the pancreas, on the other hand, leads to excessive loss of both fat and nitrogen in the fæces (Wollaeger et al 1948, Nicolaysen and Ragaard 1955) Increased excretion of fat and nitrogen in proportion to the pancreatic damage was found also in patients with chronic relapsing pancreatitis (Dornberger et al 1948) Pancreatic enzymes were absent in case 1, but this did not prevent a rise in the serum-protein level within a few weeks from 4 7 to 5 8 g per 100 ml Although at times high-protein diet and intravenous infusion of comparatively small amounts of albumin seemed to restore quickly the malabsorption defect (second readmission of case 2), at other times large parenteral infusions of plasma yielded at best an improvement for only a few days, followed by death (case 1, third readmission)

During the siege of Budapest Véghelyi (1948) noticed that babies fed on a diet poor in animal proteins developed gross œdema and severe fatty infiltration of the liver following decrease in pancreatic secretion The development of pancreatic failure took only one or two weeks, the younger the child the quicker was the failure The whole process could be reversed within a few days if enough milk or methionine was given It was much harder to reverse, or became irreversible, if treatment started later in the illness The macroscopic appearance of the pancreas was in these cases almost normal, but microscopy showed small shrunken acinar cells, with depletion of the cytoplasm and disappearance of the zymogen granules, fibrosis, and scarring By experimental feeding similar changes were produced in rats, and the excretory changes in the pancreas preceded fatty infiltration of the liver Davies (1948) described the atrophy of the acinar cells in the pancreas, with a diminution in the numbers of secretory granules, gross fibrosis, and dilatation of the ducts, as the fundamental lesion in kwashiorkor, which was necessarily followed by extensive fatty infiltration of the liver " In a man of 24 the pancreas had been almost completely superseded by fibrous tissue ", a description very similar to our case 1

Friedman and Friedman (1946), by giving a protein-poor diet to rats, produced a loss of cytoplasm in the acinar cells of the pancreas until only a thin rim remained round the vesicular nucleus Fatty infiltration of the liver was present in all the rats Similar changes were produced by giving ethionine (an antagonist of methionine), the lesions could be prevented by previous administration of methionine but not cystein or glucose, both of which usually prevent fatty infiltration of the liver (Farber and Popper 1950) Moreover the pancreas produces more enzymes on a diet high in complete proteins (containing all essential aminoacids) than on a diet that is either low in proteins or does not contain complete proteins—e g , gelatin and zein (Magee and Anderson 1955)

From these experiments it appears that the normal structure and function of the pancreas depend greatly on an adequate supply of complete proteins The experiments are also in agreement with the clinical, experimental, and pathological work of Davies (1948) and Veghelyi (1948) and with newer findings that severe atrophy of the acinar cells, with fibrosis of the pancreas of whatever ætiology, produces necessarily an extensive fatty infiltration of the liver (Bras et al 1956) Furthermore Veghelyi et al (1950) have shown that, in early cases, an adequate supply of proteins was followed within ten days by clinical improvement and by a rise in the serum-protein level, improvement, if any, in more chronic cases took much longer This observation is borne out by my own experiences both patients reported here improved quickly after being given a high-protein diet during their first readmission The serum-protein level in case 2 rose during the second readmission from 3 2 to 5 8 g per 100 ml within three weeks on a high-protein diet and intravenous dried serum-albumin 25 g daily, and coincidentally the gross generalised œdema and bilateral pleural effusion disappeared completely, and no further relapse occurred during the subsequent five years In case 1, however, where the readmissions occurred only at a more severe stage of the disease, recovery was impossible

In the two cases here recorded this postoperative malabsorption state led to the typical syndrome of secondary protein malnutrition All the evidence suggests that the pancreas, the organ with the greatest protein turnover in the body, has a key position in the development of the protein-malnutrition syndrome It appears that the vicious circle leading to the more severe stages of protein malnutrition and eventually to death might be arrested nearly at any stage—e g , fatty infiltration of the liver, and partial pancreatic fibrosis—provided that structural changes are still reversible, but, when extensive shrinking of the acinar tissue, with gross atrophy of the parenchyma of the pancreas and massive fibrous replacement and scarring, has taken place, interrupting communication between pancreas and duodenum, as in case 1, no reversion is possible

Summary

Two patients are reported who developed a syndrome of protein malnutrition, hitherto undescribed, some years after pancreaticoduodenectomy

The possible mechanism of the malabsorption leading to secondary protein malnutrition is discussed

My thanks are due to Dr T St M Norris and Mr Rupert Corbett for asking me to see cases 1 and 2 respectively, for much advice, and for permission to publish, to Dr T Moore, Dr I M Sharman, and Dr E Montuschi for their help, and to many colleagues in this country and overseas who discussed several aspects of protein malnutrition with me, particularly Prof J F Brock, Prof J N P Davies, Prof Kenneth Hill, and Prof B S Platt, and Dr W I Card, Dr H C Trowell, Dr J C Waterlow, and Dr Cicely Williams

“FALSE” SICKLE CELLS

UNDER THE POLARISING MICROSCOPE

J CAMINOPETROS
M.D Athens

J PAPASTAMATIOU
CHIEF OF SERVICE, INSTITUTE OF GEOLOGY AND SUBSURFACE RESEARCH, ATHENS

C CHLOUVERAKIS
M D Athens

SICKLE-CELL trait and sickle-cell anæmia can be distinguished from one another by examining fresh preparations of the venous blood under anaerobic conditions (Sherman 1940) In persons with the trait less than 1% of the erythrocytes are sickled, whereas in sickle-cell anæmia the proportion is 30–60%

During research in the Petromagoula area, where sickle-cell anæmia and trait are prevalent (Choremis et al 1953, 1957), 37 members of the families of 12 patients were found to have the trait In fresh preparations of their venous blood, with added sodium metabisulphite, sickle cells appeared after six to twelve hours' incubation, a holly-leaf form being predominant (fig 1)

Silvestroni and Bianco (1946) in Italy, noted differences in the sickling between patients and carriers of the trait In the carriers the sickling took longer to appear (sometimes twenty to twenty-four hours) Only a small proportion of the cells assumed the holly-leaf form

Sturgeon et al (1955) described in sickle-cell-D disease a slow and limited sickling, with holly-leaf forms predominant, whereas in sickle-cell anæmia sickling was rapid and complete

In 1952 we observed in healthy persons a slow sickling limited to a small proportion of red cells, but this was subsequently held to be false (Caminopetros 1952, Choremis et al 1953, Lie-Injo Luan Eng 1953) Our sickle cells were ascribed to external stresses—notably, long incubation In general, sickling of cells after more than twelve hours' incubation, even where it is complete, is taken as false Thus, in the Kakwa tribe the sickle-cell incidence rose from 12% to 25% when the preparations were left overnight (Lehmann and Raper 1949), and this increase was attributed to the appearance of false sickle cells On the other hand it is difficult to see why

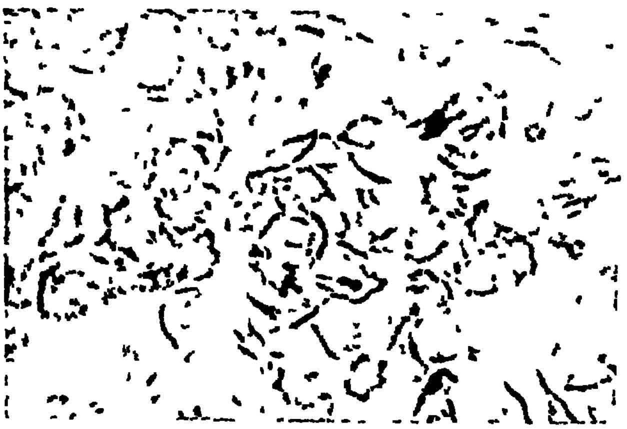

Fig 1—Sickle-cell trait Moderate sickling Predominance of holly-leaf forms. (×550)

“false” sickling has so far been observed only in peoples who exhibit the trait, and not in the blood of Europeans, in whom it is absent

Since 1952 we have seen 106 new cases of the limited form of sickling (fig 2) Of the people showing it, some come from the Greek mainland or islands, while others are Greek and Armenian refugees from Asia Minor or gipsy settlers in Greece Some of them—not always related to patients with anæmia—have signs of the trait such as target cells, and increased resistance of red cells Nevertheless it was still necessary to prove the existence of S hæmoglobin in these cases, since this is thought to be the agent responsible for sickling (Pauling et al 1949)

The characteristic optical property of S hæmoglobin, either in sickle-cells or in its solutions is birefringence, and this is seen under the polarising microscope (Sherman 1940, Perutz and Mitchison 1950, Ascenzi and Silvestroni 1953) We decided to ascertain whether the so-called false sickle-cells were birefringent

Our examinations were made at the Institute of Geology with a ‘Panphot’ Ernst Leitz polarising microscope Its arc lamp provided the necessary high-intensity light The choice of objective (P6L 45 1) and eyepiece 12x were satisfactory

Blood from 73 of our 106 cases with slow and limited sickling was examined, on the first or second day of the appearance of *sickle-cells* Unlike the red cells of normal discoid form, all these cells exhibited definite birefringence (fig 3)

These findings point to the presence of S hæmoglobin Hence the sickling in these cases, though restricted and incomplete, must be due to intrinsic factors It is not an artefact

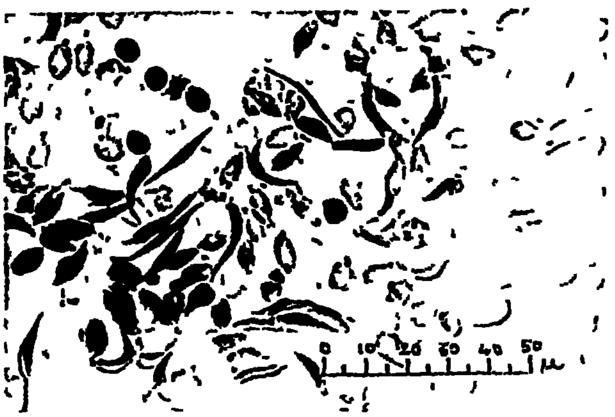

Fig 2—Slow and limited sickling after 8 hours incubation

We now think it probable that sickle-cell anæmia is caused by multiple genetic factors, and that the complete form of sickling may decline to minor forms, and eventually be extinguished

It is well established that in the sickle-cell trait the amount of S hæmoglobin ranges from 22% to 46% An exceptional case has been reported in which it was 5%, but the red cells could not be sickled The amount of S hæmoglobin in cases with slow and limited sickling will have to be determined We may note, however, that the abnormality of the red cells is not confined to the hæmoglobin but *extends to the cytoplasm and the cell* membrane (Perutz and Mitchison 1950, Ponder 1951)

Summary

In 73 cases showing the slow and limited sickling which was described in 1952 the sickled red cells have been examined under a polarising microscope They were found to be birefringent, as in cases of complete sickling

This finding supports the view that the sickling observed, though slow and limited, is genuine—not false, as has been suggested

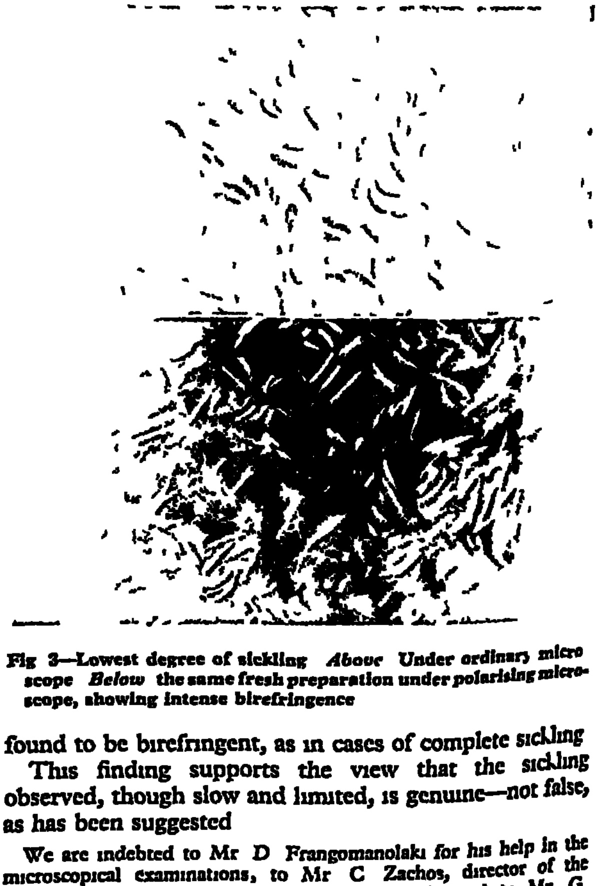

Fig 3—Lowest degree of sickling *Above* Under ordinary microscope *Below* the same fresh preparation under polarising microscope, showing intense birefringence

We are indebted to Mr D Frangomanolaki for his help in the microscopical examinations, to Mr C Zachos, director of the Institute of Geology and Subsurface Research, and to Mr G Marinos, chief of service of the institute

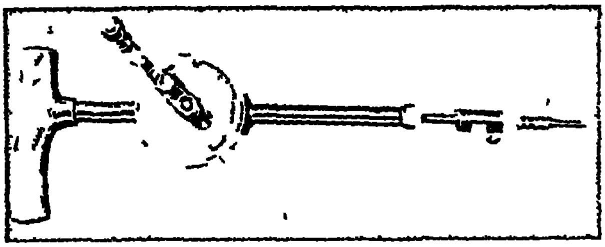
New Inventions

A NEEDLE TREPHINE

FOR the past three years I have used a needle trephine which can be readily made in any laboratory The trephine has been used both manually and with electrical power It has been employed in man and laboratory animals for placing surface electrodes, and deep cortical electrodes, emergent exploration of the subdural space and subarachnoid space, placing needle electrodes in the deep nuclei of the brain, and tapping the ventricular system for placing air and phenolsulphonphthalein solution for evaluation of the ventricular system

The trephine is made by taking a 16-gauge lumbar-puncture needle, and filing a groove in the hilt of the needle 90° from the original groove that receives the locking tongue of the stylet The stylet is then rotated 90° from its normal position and set into the prepared groove The needle with the stylet in place is then sawed at 45° angle 2 cm from where the hilt begins The opposite side of the needle and stylet are filed to a 45° angle from the horizontal Once this is done, the stylet is rotated again back to its normal, originally designed position which makes for a point with opposing 45° angles resulting in serrated or cutting edges

A small adapter was made out of brass which receives the hilt of the needle and is locked into place by a set screw The opposite end of the adapter has a straight shaft which can be fitted into a Jacob's chuck or into a locking twist drill chuck (see figure)



Twist drill, chuck adapter, and needle trephine

The obvious advantage of this needle trephine is that it perforates the skull without a surgical incision With the stylet of the needle trephine in its normal position, the scalp is perforated under local anaesthesia as a puncture Once the outer table of the skull is encountered, the stylet of the needle is turned into its cutting position of 180°, and the hilt of the needle is placed into the adapted chuck With a limited number of turns, the needle passes through the tables and the needle can be felt making its final break through the inner table The length of the needle precludes it going more than a few millimetres beyond the inner table If the needle trephine has been directed properly for the intended target, the smaller needle or the needle electrode can be taken and advanced through the trephine needle In the case of a ventriculogram, a no 20 smooth bevelled needle can be directed into the lateral ventricle If the line of flight of the needle trephine has not been properly directed, it is necessary to remove the needle trephine and to advance the smaller ventricular cannula or the smaller electrode needle in the proper direction, which is possible because these needles are small compared to the trephine needle, and their direction can be changed The puncture opening in the scalp is readily sealed with 'Aeroplast'

The needle trephine has all the disadvantages of the twist drill holes, but these disadvantages are outweighed by the simplicity when it is not desirable to display the brain surface I have not employed this drill in tumour biopsy, or to tap cerebral or suprasella cysts, but the instrument would lend itself well to these procedures With it I have placed over 100 trephine openings over various areas of the skull There has been no infection or hæmorrhage The procedure is not unduly painful to the patient

Reviews of Books

Attempted Suicide

Its Social Significance and Effects E STENGEL, M D, M R C P, professor of psychiatry, University of Sheffield, NANCY G COOK, A M I A, psychiatric social worker Maudsley Monographs no 4 London Chapman & Hall, for the Institute of Psychiatry 1958 Pp 136 25s

SUICIDE is a subject of great psychiatric and sociological importance with many unsolved and even unexamined problems In 1952 Professor Stengel first pointed out that the environmental setting of attempted suicide and its repercussions on society had never been adequately investigated, partly because it was assumed that successful and unsuccessful suicides formed a homogeneous group He propounded a number of questions for future research, some results of which were summarised in 1956 and are presented in detail here He and his collaborators have studied " the relation of the individual to the social environment in the course of the suicidal attempt ", its " effects on the person's social relationships ", and " the reactions of the human environment and of society " in five groups totalling 630 patients admitted to hospital (three groups in observation wards, one in a psychiatric hospital, and one in a general hospital) and compared them with a series of suicides from a coroner's court Two of the groups followed up for as long as six years confirmed the clinical impression that only a minority finally succumbed to suicide They conclude that attempted and successful suicides should be regarded " as two different though overlapping populations " In contrast to suicide, " suicidal acts irrespective of psychiatric background " are " incidents in the course of struggle for adjustment social behaviour patterns " not " self-destructive " but " an alarm signal " or " appeal to the human environment "

This thesis is probably correct for a proportion of cases but applied to all seems an oversimplification on the authors' own evidence It does not explain the steep rise of suicidal attempts in the last decade—partly due to the easy availability of sedative drugs for minor psychiatric disturbances—at a time when social conditions and community care have steadily improved Nor can it explain suicidal attempts in response to hallucinations, delusions, the conviction of severe illness, fear of insanity, and insomnia, or following crimes of violence or suicide pacts, or in patients already living a sheltered community life, as in mental hospitals

The book makes difficult reading, partly because of its style The text is broken by 33 tables, not all helpful or readily comprehensible 44 representative case-histories, varying in length from 4 lines to almost a page, demonstrate that to obtain and present sound psychiatric case material is the chief difficulty in studies based on large numbers of patients

The Art of Clinical Refraction

T H WHITTINGTON, M D, M R C P, D O M S, ophthalmic physician, the Royal Eye Hospital, London London Oxford University Press 1958 Pp 294 30s

DR Whittington has succeeded in animating refractive work, and his readers will be stimulated by his zest and interesting presentation of clinical problems in a subject too often considered dull and dry Although refraction is a small part of ophthalmology it is a large part of routine practice for most ophthalmologists An intelligent appreciation of all the factors concerned in a patient's visual discomfort, and a conscientious application of the necessary subjective and objective tests, are essential for the relief of symptoms and reassurance of the patient

The book is practical and devoid of higher mathematics, and its value lies in the physician's approach to the art as well as the science of refraction Criticism concerns trifling errors Fig 57 (*a*) and (*b*), to illustrate the actions of the superior and inferior oblique muscles, are incorrectly drawn to meet the description in the text, and fig 54 (the Maddox rod test) would look better if all the vertical test results were set out in one row and the horizontal in the other "Spasmodic" is perhaps an inappropriate description for contractural torticollis (wry neck) of orthopædic interest

The author has put into the book much wisdom, the outcome of long clinical experience, enriched by the human interest he has taken in his patients It will therefore be of particular value to the young ophthalmologist—and indeed to many of maturer years

Enzymes

MALCOLM DIXON, SC D , F R S , reader in enzyme biochemistry in the University of Cambridge, fellow of King's College, Cambridge, EDWIN C WEBB, M A , PH D , lecturer in biochemistry in the University of Cambridge London Longmans, Green New York Academic Press 1958 Pp 782 90*s*

THIS is a scholarly and original book involving much of the authors' highly personal and critical approach to enzyme problems in addition to a comprehensive survey of the literature of known enzymes The subject is treated at a level suitable for research-workers and advanced students The book is mainly concerned with the elucidation of general principles underlying the nature, structure, mechanism of action, and kinetics of enzymes, and is only secondarily an account of the more functional aspects of the role of enzymes in metabolism In order to clear the ground for the very full treatment of basic principles, factual data concerning individual enzymes, including details of sources, substrates attacked, activators, and the chemical reactions catalysed, have been grouped together in encyclopædic tables Thus table V is a list of 659 enzymes occupying 42 pages arranged according to the reaction-type and thought to include, with literature references, all clearly identified enzymes described up to 1957 The classification follows that already brilliantly sketched in 1949 in Dr Dixon's small book *Multi-enzyme Systems* A valuable step forward in enzyme classification has undoubtedly been achieved This book is a highly valuable contribution to knowledge of and should become a standard work on the basic principles of enzymology

Laboratory Medicine Hematology

JOHN B MIALE, M D , professor of pathology, University of Miami School of Medicine, director of clinical pathology, Jackson Memorial Hospital, Miami, Florida London Henry Kimpton 1958 Pp 735 112*s* 6*d*

THIS is not a book for physicians, as the title is understood in this country, but for clinical pathologists, and really for those specialising in hæmatology The general clinical pathologist may find it useful as a reference book, for it is detailed, up-to-the-minute, and surprisingly complete But the effort to make it complete has involved the author in masses of detail that do not make easy reading or allow him to give clear indications for action Much of the information is helpfully gathered into tables, but, in a manner often seen in American texts, they give no indication about relative importance Thus, table 22 lists 34 chemicals that have caused methæmoglobinæmia, together with 6 other causes, including "ingestion of coloured wax crayons or chalk", table 67 lists 55 causes of eosinophilia—a remarkable feat, though few of the causes are important in practice A more valuable section lists 37 cases of interpretation of bone-marrow findings, giving brief details of the history, physical examination, and other pertinent laboratory findings together with a discussion of how all this material was put together in reaching a diagnosis This is indeed the stuff of medicine, but this method is not used in other sections It is hard to find any point in hæmatology that is not mentioned for example, the book includes the changes in the differential white-cell count from birth to 21 years, the laboratory findings in the hæmoglobinopathies, including Hb-I trait, and the recommended types of blood or blood product for transfusion in blood diseases

The bibliography is immense and all titles are given of papers listed The illustrations are mostly black-and white, but some are from colour photomicrographs, the reproduction of the colour photographs is not very good, Professor Miale knows well the diagnostic importance of clear nuclear detail in erythroblasts, but the pictures of *pronormoblast* and other normoblasts show featureless magenta blobs for nuclei The book will find its most popular use among the reference works in the clinical laboratory

Ulcerative Colitis

HARRY E BACON, B S , M D , SC D , LL D , F A C S , F A P S , *professor and head of department of proctology, Temple University, Philadelphia* Philadelphia J B Lippincott London *Pitman Medical Publishing Co 1958 Pp 395 120s*

Dr Bacon is well known to British proctologists not only through his many writings but as a man of thoroughness and energy A book from him, therefore, on the topical subject of ulcerative colitis is welcome—all the more so because only two other works are solely devoted to this subject This latest one is essentially factual in its approach and has the virtue of being comprehensive with but *few omissions of reference to relevant* work The ætiological hypotheses are presented fairly Surgical detail is contained only in the last half of the work, and earlier chapters contain much useful information, ranging from pathology, diagnosis, and complications to conservative therapy, including the use of steroids Appropriately a chapter on the effect of the disease on pregnancy and vice versa is included The book is illustrated profusely, and sometimes superfluously—*a pity, since the cost is high for a work on a subject with* limited appeal

External Collimation Detection of Intracranial Neoplasia with Unstable Nuclides

G M SHY, M D , M R C P , R B BRADLEY, B S , W B MATTHEWS, Jr , B S , department of health, education and welfare, Bethesda, U S A Edinburgh and London E & S Livingstone 1958 Pp 144 30*s*

THE title of this book reflects fairly its highly technical content and style of expression Injections into either the arteries leading to the brain or the cerebrospinal space to confirm the diagnosis of a cerebral tumour cause discomfort to the patient and carry certain hazards The *development of* alternative methods for detecting and localising tumours *within the skull is clearly important The authors* recount their experience in using radioactive isotopes, which may be concentrated in neoplastic tissue The position of the tumour may be determined by the use of external counters with little disturbance to the patient The work described here is an advance in a difficult field, but it might perhaps have been more suitably published in shorter form, in plainer English, in a *specialised journal*

The Excitable Cortex in Conscious Man (London Liverpool University Press 1958 Pp 43 10*s* 6*d*)—This little book, which is a transcript of Dr Wilder Penfield's Sherrington lecture, gives a brief survey of some of his work, with various colleagues, on the response to electrical stimulation of the human cerebral cortex exposed after craniotomy under local anæsthesia The information obtained in this way is, as Dr Penfield is careful to emphasise, a by-product *of* surgical procedures undertaken with a definite therapeutic end in view *Two cases of epilepsy* in which elaborate psychical phenomena were elicited are described in some detail, but much of the book is devoted to an account in general terms of the properties of the cortical regions revealed by electrical stimulation and to schemata illustrating the author's interpretation of these properties If at times the argument seems a *little facile*, it must be allowed that in a necessarily abbreviated and primarily viva-*voce presentation* some elision is scarcely avoidable The book can be recommended not only as a convenient up-to-date summary of, but also a readily assimilable introduction to, the fascinating work done in the author's clinic

THE LANCET

LONDON 6 SEPTEMBER 1958

More New Steroids

The synthesis of new steroids, measurement of their effect in animals, and submission of selected examples to clinical trial are proceeding with increasing momentum Modifications of the cortisone or hydrocortisone molecule which have yielded substances of therapeutic interest have included the insertion of a double bond in ring A, a halogen atom at C19, and a hydroxyl or methyl group in the α configuration at C16 Singly or in combination these changes have produced substances of widely different character Fludrocortisone, the 9-α-fluoro- derivative of hydrocortisone,[1] is a much more potent "anti-inflammatory" agent than its parent steroid but is limited in its clinical applications by an even greater enhancement of sodium-retaining activity The unsaturated derivatives of cortisone and hydrocortisone, the δ or "predni" steroids—prednisone and prednisolone—are also more active anti-inflammatory agents than their precursors but have very little mineralocorticoid activity except in very large doses In addition to topical application 9-α-fluoro-hydrocortisone has a place in the treatment of some cases of Addison's disease and after adrenalectomy The δ steroids have largely replaced cortisone in the treatment of diseases such as rheumatoid arthritis and asthma, their weak mineralocorticoid activity is an asset, and in rheumatoid arthritis they promise to maintain control beyond the time when the effect of cortisone begins to wane

At the International Congress on Rheumatic Diseases last year the effects of a still newer steroid, triamcinolone, were discussed by Freyberg et al[2] This substance, prepared by Bernstein et al,[3] is hydrocortisone modified by a double bond in ring A, a fluorine atom at C9, and a hydroxyl group at C16 The last of these modifications converts a powerful mineralocorticoid into a substance with a sodium-diuretic action, its anti-inflammatory activity is slightly greater than that of prednisone or prednisolone Clinicians are unlikely to be impressed by the ability of a 4 mg tablet of triamcinolone to do the same good work as a 5 mg tablet of prednisolone unless the former has other advantages From several reports it is obvious that triamcinolone has some side-effects not shared with other steroids, among these Freyberg et al[2] mentioned severe headache, dizziness, anorexia, nausea, fatigue, and progressive loss of weight, but peptic ulceration did not occur In our columns this week Dr Dudley Hart and his colleagues report a comparison between the effects of prednisolone and triamcinolone in rheumatoid arthritis At a 4 5 dose ratio of triamcinolone to prednisolone the former was slightly more effective. Dyspepsia often persisted when triamcinolone was substituted for prednisolone, but no final conclusion was reached about the comparative risk of peptic ulceration Shelley et al[4] have reported that triamcinolone is effective in psoriasis—a disease which responds poorly if at all to other steroids Of 31 patients with systemic lupus erythematosus treated by Dubois[5] with triamcinolone, only 1 developed a new peptic ulcer, and a pre-existing ulcer healed during treatment with the steroid. Hart et al did not observe any of the unusual side-effects of triamcinolone except postprandial flushing Some of Dubois' patients, treated with much higher doses, developed profound weakness of muscles —particularly the extensors of the legs and the deep muscles of the back This disturbing effect was limited to women and slowly disappeared when prednisone or hydrocortisone was given instead of triamcinolone Furthermore many patients gradually lost weight—only partly from loss of fluid—and hirsutism and striæ were more prominent than in patients treated with other steroids The men in this series showed no "cushingoid" features, and for this reason Dubois believes that triamcinolone may be the steroid of choice in men. Of these patients with systemic lupus erythematosus most felt better during treatment with triamcinolone than with other steroids A hitherto unreported and unexpected effect of triamcinolone is described on another page by Dr Wells 3 patients treated with the steroid—1 for thrombocytopenic purpura and 2 for asthma—developed pains in their joints In 2 of these patients the appearance of the joints mimicked rheumatoid arthritis, in all 3 the arthropathy disappeared when prednisolone was substituted for triamcinolone It is conceivable that the patient with thrombocytopenic purpura had lupus erythematosus and that the joint symptoms were part of this disease, it is hard to explain their appearance during treatment with triamcinolone (but not with prednisolone) and equally difficult to explain the similar sequence in the patients with asthma The balance of evidence seems to suggest that arthropathy was a direct effect of the treatment. Clearly much more must be learnt about the advantages and disadvantages of triamcinolone It may at times be rather more effective than the δ steroids, it may (by virtue of its diuretic activity) be useful in patients with cardiac decompensation, and in those who gain weight rapidly, or whose blood-pressure rises, when treated with other steroids It shows considerable promise in psoriasis Further evidence is needed about the risk of peptic ulcer or osteoporosis—major bugbears of steroid therapy—although it has been claimed that it is less likely to provoke these effects than other steroids The muscular weakness described by Dubois may be troublesome only when high doses have to be used The unexpected effect in Wells' patients will clearly repay close study

Yet another new steroid has been brought into clinical use. This has the same structure as triamcinolone except that a methyl instead of a hydroxyl group occupies the 16α carbon position This substance, hexadecadrol ('Decadron'), synthesised in the laboratories of Merck, Sharp & Dohme, was used by Boland[6] in 21 cases of rheumatoid arthritis It proved to be 5–10 times as potent as prednisolone in controlling the disease, significant gastrointestinal symptoms did not develop, but the trial was preliminary and too brief for judgment of side-effects In animals the anti-inflammatory effect was 190 times that of hydrocortisone, but the glycogenic activity was enhanced by a factor of only 17. Sodium retention was not demonstrable in adrenalectomised rats The dissociation of anti-inflammatory and glycogenic activity, which are so closely related in other steroids, is striking, and reports on the long-term clinical use of this steroid will be awaited with interest

In assessing these products of the ingenuity of steroid chemists, potency is important only as a factor in the therapeutic ratio Dissociation of desirable from undesirable effects would be a great step forward

Thymectomy and Myasthenia Gravis

The association between abnormalities of the thymus and myasthenia gravis was recognised over half a century ago In most series of myasthenics rather more than a tenth have radiologically demonstrable enlargement of the thymus, and hyperplasia has been observed in over half the myasthenic thymuses examined histologically Nevertheless the precise relation between the thymus and myasthenia remains something of a mystery, for, although it would be easy to assume that the thymus produces a curare-like substance which interferes with neuromuscular transmission, it may be that an independent process, as yet unidentified, results simultaneously in the myasthenic state and enlargement or hyperplasia of the thymus The hyperplastic thymus may then in its turn accentuate and perpetuate the myasthenic muscular response The notion that myasthenia is accompanied by structural changes at the motor end-plate and is not necessarily due to some hypothetical thymic secretion is now receiving the attention it undoubtedly deserves, and we hope that the lead given by Woolf et al[7] proves profitable Wilson et al[8] showed that the myasthenic thymus has a high neuromuscular-blocking activity, and also that the greater the benefit of thymectomy in a given case the greater had been the blocking activity of that particular thymus On the other hand the thymus of children and of an adult who was certainly not myasthenic (this specimen was obtained at necropsy) also exhibited a high blocking activity Furthermore extracts of thymus from undoubted cases of myasthenia exhibited no high blocking activity In other words the link is not so obvious or so direct as some workers would have us believe The simple notion of thymic secretion fails to take into account the curiously selective affection of the ocular or bulbar muscles noted particularly by Grob[9] and by Ferguson et al,[10] and also seems difficult to reconcile with the fact that exercise of one part of the body may aggravate the myasthenic response in another[11]

Because of the conflicting physiological and pharmacological evidence we must turn to the evidence from clinical studies Is it in fact certain that surgical removal or radiotherapeutic destruction of the thymus is followed by significant improvement in myasthenia? Since Blalock[12] in 1939 reintroduced this operation, workers at various centres have considered the statistical evidence in the most careful and painstaking way In 1954 we concluded[13] that "until criteria for selection are improved, thymectomy will not commend itself for patients well maintained under medical management, those with localised ocular myasthenia, those in the older age-groups, or those with longstanding symptoms The choice of treatment remains most difficult in the young myasthenic with generalised symptoms and a short history Keynes's good results will influence some physicians in their choice, while the findings at the Johns Hopkins Hospital and the Mayo Clinic will make others hesitate" The allusion to Johns Hopkins related to the work of Grob,[9] who had concluded that there was no striking difference between the results of thymectomy and those of medical management, the Mayo Clinic workers were Eaton and Clagett,[14] who in 1950 had also found no significant statistical difference These two workers have since revised their opinion[15] Their initial conclusion that thymectomy had no significant beneficial effect seems to have sprung from their not at that time considering thymic tumours in a separate group Recent surveys have shown that in patients with such tumours the mortality is apparently not lowered by operation, which, however, may improve the myasthenic state for a time It seems possible that the best treatment in these cases may prove to be radiotherapy, for the postoperative death-rate is not inconsiderable Keynes[16] recommended surgery in these thymomatous cases only after radiotherapy had been applied, but alluded to three patients who remained well after radiotherapy without operation It is perhaps surprising that a tumour in the thymus should render removal of that organ less beneficial than in cases where there is no tumour, but this is in keeping with the generally paradoxical role of the thymus in myasthenia

Simpson[17] has now reviewed 404 cases of myasthenia comprising those seen at the National Hospital for Nervous Diseases together with those dealt with by Keynes in his extensive series of thymectomies Simpson was able to trace 374 of these 404 patients, and 245 of the 374 had survived Of these 245, 181 were re-examined, and the remainder completed a detailed questionary. The total series comprised 294 patients who had undergone thymectomy and 110 who had not been operated on. SIMPSON recognises the difficulties inherent in the statistical assessment and acknowledges that this series lacks any planned control, but feels that even so certain conclusions are justifiable. He expresses the opinion that this and the three American[9 14 15 18] series indicate that operation provides a worth-while improvement in prognosis for women with myasthenia, particularly by reducing case-mortality. In the London series women had a mortality of 15·4% from myasthenia or postoperative causes; and this certainly compares very favourably with the figure of 28·8% for deaths in the unoperated group. The figures for males suggest that operation reduced mortality hardly at all. As to the status of the survivors, it is clear that this differs widely at any given time both in the operated and in the unoperated. SIMPSON finds that in those not operated on mortality is higher in females than males, and that fewer women reach the higher categories of activity, whereas in those who have been operated on this trend is completely reversed. It seems that a shorter preoperative duration is likely to result in a higher physical status among survivors, but has little or no influence on the risk of death after operation.

With each new case of myasthenia the clinician must face the problem of whether to advise thymectomy or not in that particular instance. FERGUSON et al.,[10] reporting the results of the medical management of 75 patients, commented on the benign course of the ocular type of myasthenia—to which attention had been previously drawn by GROB,[9] who had followed 48 such cases for an average period of 8·5 years without encountering a single death. OSSERMANN et al.[19] suggest that juvenile cases of myasthenia gravis and those with highly localised manifestations do not need thymectomy, whereas the more generalised and acute types, progressive and unresponsive to medical treatment, may be submitted for thymectomy, but they do not give figures to indicate results. In the light of the present evidence it seems reasonable to conclude that young females with generalised myasthenia of short duration should be regarded as eminently suitable for operation, since among them operation results, in a significant saving in life and a lasting improvement in the myasthenic state. At the other end of the scale the patient with ocular myasthenia which has not spread to the general musculature within two or three years is likely to carry on quite well under medical management, and may in fact have a long spontaneous remission. When a tumour is present, radiotherapy will usually be preferred, though some workers recommend radiotherapy followed by operation. For the remainder it is impossible to generalise, the therapeutic plan will be conditioned by the personal views of the clinician, and by the patient's age, occupational and social circumstances, and personal wishes.

Annotations

UNEXPECTED DEATH IN INFANCY

IN infancy unexpected deaths have a special importance because of the distress they cause, often including tragic self-reproach by the parents. Though, by their very nature, they must commonly be unavoidable, even a small reduction in their number would be very well worth achieving. But better preventive measures must wait on better understanding of the reasons why babies die unexpectedly, and this is most likely to come from carefully planned studies by teams of experts. The inquiry into "sudden death" in infancy, organised by Prof. Leslie Banks, of Cambridge, at the request of the Ministry of Health, is therefore welcome, and his interim report, describing the work arranged by the very knowledgeable steering committee,[1] will command attention.

It describes, in fact, only a pilot investigation made in selected London areas, and in Cambridge and the surrounding district during the two years ended March, 1956. Moreover, since the main object was to gain experience for use in the subsequent full-scale investigation, alterations were made from time to time in the method of inquiry, in the routine for collecting material, and in the forms used for recording information. Hence what we are now given is to be regarded as no more than a report on progress, and its chief value lies in indicating the means by which such an inquiry may best be pursued and the lines of research which are likely to be most rewarding.

It is based on a study of 81 cases of sudden death between the ages of 2 weeks and 2 years, and the information obtained is considered in its pathological, microbiological, and social aspects. 64 of the infants died in London and 17 in the Cambridge area. In 38 of the 52 London infants examined histologically, evidence of tracheobronchitis was found, and in a proportion of these cases a special technique, not described in the paper, was used to demonstrate a characteristic tracheobronchial lesion. The tracheobronchitis was regarded as possibly of viral origin but viruses were actually isolated in only 2 of 50 infants examined for them. The remaining 14 London infants who were examined histologically had purulent respiratory infections, septicæmia, or gastroenteritis. In contrast, no definite "cause of death" was found in 13 of the 17 Cambridge cases, while infections (bronchiolitis, bronchopneumonia, septicæmia) were found in the other 4. Though the report does not compare the two series in detail, it seems possible that the London group of infants who had tracheobronchitis was similar to the Cambridge group in whom the cause of death was uncertain, and that the disparity in findings was due to differences in histological technique. On the other hand, the Cambridge workers may have been dealing with quite another problem, since the two groups differed (though perhaps not significantly) in sex-incidence, seasonal incidence, and the proportion of sudden deaths to all deaths at this time of life. It would be interesting to know more

1 Banks, A. L. *Mon. Bull. Minist. Hlth Lab. Serv.* August, 1958, p. 152.

the criteria for diagnosing "tracheobronchitis, ...bly of viral origin" in the London infants, since interpretation of histological changes is always to some extent subjective [2, 3]

Bacteriological studies were made in 66 of the 81 cases, and in about half of these the lungs were sterile on culture or contained only the normal flora of the upper respiratory tract In most of the other cases, gastrointestinal organisms were cultured from the lungs, but the meaning of their presence is doubtful, since postmortem contamination could not be excluded Pathogenic organisms, including *Staphylococcus aureus* and *Hæmophilus influenzæ*, were found in 9 of the 66 cases The only conclusion drawn from the microbiological evidence was that infection with pathogenic bacteria is probably not an important factor in causing sudden death in infancy

Various workers have found a higher incidence of unexpected deaths during the winter months, and a preponderance of male infants [4] In the present inquiry both these observations were confirmed for the series as a whole and for the London series, though not for the smaller Cambridge series, in which the sex-incidence was roughly equal and cases occurred almost uniformly throughout the year The report suggests that poor general health, premature birth, illegitimacy, poor maternal care, or poor social circumstances, while not causes of sudden death, may increase the risk one or more of such handicaps was recorded in 44% of cases Accidental suffocation in a soft pillow or by overlaying caused few if any of these deaths, but the possibility that a considerable proportion followed the inhalation of food or vomit could not be excluded

A remarkable statement in the social section of the report is that cases of sudden death formed 25% of all deaths in the age-group and that in Cambridge the figure was as high as 44% This high proportion raises the question whether all these so-called sudden deaths would ordinarily be regarded as unexpected deaths Data from the Registrar General showed that, in 1955, 20 5% of deaths between the ages of 2 weeks and 2 years were "certified by a Coroner as being due to influenza, pneumonia, bronchitis, or other respiratory cause, or as due to obstruction, inhalation, ingestion, or accidental mechanical suffocation" Professor Banks' report says that these deaths are comparable to those considered in the inquiry, but this seems arguable For example, deaths due to ingestion would presumably include cases of accidental poisoning, whereas other accidents, such as road accidents, are considered as "clearly outside the scope of the investigation" The full account of this study could usefully define more precisely what is meant by the terms "sudden death" and "unexpected death" in infancy

The general conclusions of the committee so far are in line with most previous work in suggesting that, while the causes of sudden death in infancy are largely unknown, mechanical factors such as overlaying and accidental suffocation are comparatively rarely responsible, while respiratory infection, possibly by a virus, is an important factor in most cases Nothing emerged from the pilot investigation to explain why apparently mild infections should cause death in these infants, and this is perhap the crux of the problem [8] The results of the main inve tigation, based as it is on so much careful and methodical preparation, will be eagerly awaited

CARPAL BOSSING

CARPAL bossing was first described by Fiolle [5] in 1931, and since then the condition has rarely been noted outside France It consists of a painful prominence of the dorsum of the base of the third metacarpal and capi tate, visible on radiographs as a small exostosis and containing bone Most patients present with aching pain, a detectable bony lump, sometimes a bursa, and sometimes difficulties with snapping extensor tendons Recurrences after removal seem to be common [6] The single case described by Dorosin and Davis [7] and the two cases of Menegaux [8] suggest that this is a rare disorder In a small investigation of normal subjects Larson et al [9] have now shown that prominence of the third metatarsal base was rare in children but common in adults, and present in 50% of physiotherapists They suggest that the boss is due to new bone formation resulting from use It is clea that the deformity is common, but symptoms are rare, and treatment should depend on whether it is causing inconvenience

FOOD AND VOMIT IN THE LUNGS

THE aspiration of food and vomit has been investigated by Gardner [10] He introduced barium sulphate through a gastric tube into the stomachs of ten patients immediately after death The bodies were then transferred to the mortuary, and radiographs of the lungs were taken at the subsequent necropsies In seven out of the ten, barium had entered the lungs, reaching the alveoli in several Thus, unless the trachea is blocked as soon as the patient dies, necropsy evidence of antemortem aspiration cannot of itself be considered conclusive

Gardner then studied a series of ninety-four adult male and female patients who had either undergone a major operation or were debilitated for other reasons Each had non-flocculable barium sulphate added to all drinks—in the proportion of one part in six—for two to four days The lungs were repeatedly examined radiographically, and bronchoscopy was undertaken when clinically indicated Barium entered the lungs of ten patients (11%), but in most of them it was impossible to decide whether it was inhaled during vomiting or feeding

To distinguish the incidence of aspiration of vomit from that of aspiration of food, barium was given to a further fifty-one patients directly into the stomach through a tube, so that its appearance in the lungs could be due only to inhalation of gastric contents This occurred in only one patient Gardner concludes that aspiration of food is commoner than that of vomit (it took place probably in 9–10% of the patients studied as opposed to 1–2% for vomit)—and that it is often multiple Aspiration of either is often extremely difficult to diagnose clinically The overall results suggest that one in about every ten debilitated surgical patients inhales food or vomit

The complications directly attributable to aspiration are difficult to assess, but the fact that some patients in this

series undoubtedly died as a result of aspiration suggests that greater care is needed in posturing and feeding those who are very ill Gardner believes that aspiration of vomit or food is too often the coup-de-grâce—rather than an agonal phenomenon—in an ill patient who might otherwise recover He suggests that the standard hospital feeding cup, which is designed to facilitate feeding in recumbency, should be abolished as its style contributes to aspiration Not only does the shape of the spout enable fluid to be poured into the trachea, but the hooded top ensures that the patient is taken unawares The patient should either sit up and drink out of an ordinary cup or glass or lie on his side and drink through a straw If neither is practicable, feeding should be through a tube directly into the stomach The danger associated with vomiting can be offset only by the adoption of a prone or semiprone position

OCCLUSION OF ANTERIOR SPINAL ARTERY

THE syndrome of occlusion of the anterior spinal artery is of interest because of the striking clinical picture It was first recorded in life by Spiller,[1] who called the disorder syphilitic acute anterior poliomyelitis, having recognised the distinctive involvement of anterior horn cells at the level of the lesion This description of the necropsy findings is excellent For many years the condition continued to be regarded as a manifestation of syphilitic vascular disease, but it is now clear that many patients show no evidence of neurosyphilis, indeed the cerebrospinal fluid is often normal

Ten cases seen at the Mayo Clinic since 1949 have been described by Peterman et al [2] In three the lesion involved the lower cervical region, and in seven the thoracic region of the spinal cord The onset is usually abrupt and the clinical picture is fully developed within a few hours In the lower limbs, there is sudden loss of power often with pain across the shoulders, bladder and bowels are paralysed, and appreciation of pain and temperature is lost below the level of the lesion The posterior columns, subserving joint-position sense, touch, and vibration sensibility are spared In the cervical cases there are total lower-motor-neurone lesions of the muscles supplied by the segments involved—usually C7, C8, and T1 There may therefore be very severe permanent disability due to bilateral disruption of function of the upper limbs, particularly the hands In addition there may be segmental sensory loss, presumably due to ischæmia in the central grey matter of the cord Symptoms and signs are usually symmetrical The association of an anterior-horn-cell disorder at the level of the lesion with sparing of the posterior columns points to the diagnosis

The outlook for the lower limbs is fair In all but one of the ten Mayo Clinic cases the patient could walk after a few weeks, and control of bladder and bowels was regained Wasted muscles do not recover The anterior horn cells, which seem to be extremely vulnerable to anoxia, are permanently affected

Woollam and Millen [3] agree with Feeney and Watterson [4] that the nervous system has been developed to the limit of the vascular supply hence the havoc brought about by occlusion of the anterior spinal artery Radicular arteries from vessels adjoining the vertebral column vary from two to seventeen, and two of these (one cervical and one lumbar) contribute largely to the anterior spinal artery, which is formed by the fusion of two longitudinal chains The artery supplies the whole of the grey matter except part of the dorsal horn, and it partly supplies the anterior columns of white matter The lower cervical region and the lower thoracic region are most usually involved The reasons for this are not clear It is believed that blood flows through the anterior spinal artery, from both above and below, towards the thoracic region, and the sites of election may be watersheds Another possibility is indicated by clinical considerations Some patients with occlusion of this artery show no evidence of generalised vascular disease or of disease of the vertebral column Some seem to have engaged previously in physical work involving the shoulders and back, or to have suffered exposure The dependence of the anterior spinal artery on radicular contributions suggests that vasodilatation in the thoracic muscles may lead to ischæmia in the spinal cord The converse situation has been described in which the anterior spinal artery participated in the anastomosis consequent on coarctation of the aorta at the level of the ductus arteriosus [5]

In other conditions associated with vascular lesions of the cord, such as syphilis, vertebral fracture, aortic occlusion during operation, dissecting aneurysm of the aorta, and the aortic-arch syndrome, there are obvious pathological reasons for cord involvement In many cases of occlusion of the anterior spinal artery this is not so it is not even clear whether hypertension and atherosclerosis are important in this disorder The description of well-documented cases is still of great interest

"CLEAN" VERSUS CATHETER SPECIMENS OF URINE

IT is widely accepted that specimens of urine for bacteriological investigation from female patients should be obtained by catheterisation Besides causing inconvenience and occasionally embarrassment, this procedure carries a moderate risk of introducing fresh infection, and in fact it is often carelessly performed without regard for asepsis It has been suggested that technical perfection necessitates the presence of two nurses—one to separate the labia and clean the meatus, and the other to insert the catheter

Wishing to avoid the hazard of introducing infection Boshell and Sanford [6] advocate the examination of "clean" freshly voided specimens as an alternative, and claim that these specimens compare favourably in a bacteriological sense with those obtained by catheter The suggested procedure consists in thorough cleaning of the periurethral area in a Sitz chair filled with green soap solution, followed by gentle scrubbing with pads containing 'Zephiran' (1% solution of benzalkonium chloride) The patient then voids, holding the labia apart, and a mid-stream specimen is collected for culture The results in 67 cases corresponded closely with those from subsequent catheter specimens, and the technique is recommended as a screening method to reduce the need for instrumentation It may be questionable, however, how far such arrangements are appropriate in a busy outpatient clinic or hospital ward

From the Sections of Surgery, Surgical Pathology, and Biometry and Medical Statistics, Mayo Clinic and Mayo Foundations, Rochester, Minnesota*

The Lancet of May 31 carries a letter by Ian Mackenzie which relates to the comparison of the five-year survival-rate for a group of patients treated at the Mayo Clinic by radical mastectomy [1] with the five-year rate for a group of patients treated at Edinburgh [7] by simple mastectomy and radiotherapy A previous letter from George Crile, Jr ,[2] referred to by Dr Mackenzie, deals with the same matter, as do several other letters

Comment on the comparison can be misleading without an explanation of the context of the analyses

CRITICISM OF RADICAL MASTECTOMY

The report from the Mayo Clinic, in its primary section, set forth the results, in the form of survival-rates, for a group of 9649 patients with mammary cancer who had been treated surgically over a period of almost half a century, from 1910 to 1954 In all but a negligibly few cases the treatment was by the classical radical mastectomy of Halsted (supplemented in designated cases by irradiation)

In the last couple of decades radical mastectomy has come under severe criticism In particular, McWhirter's [4,7] analysis of its putative deficiencies has led him to conclude that it should be abandoned Since 1941, under his direction, patients at Edinburgh have been treated instead by simple mastectomy and radiotherapy, with results [4–7] which he regards as better His reports have had a significant influence in the United States, and, though the superiority of simple mastectomy and irradiation has not been explicitly accepted, his arguments have undermined confidence in radical mastectomy Surgeons whose training and experience do not permit them to perform the radical operation have found in them support for performing only simple mastectomy, and some therapeutic nihilists have found support for arguing even that all treatment of cancer of the breast is futile These views have permeated to young physicians beginning their careers and (even more important) to the general public, and the effect has been confusing and demoralising Veritably an ominous situation was developing Since our own results with radical mastectomy, though not ideal, did not reflect the dire predictions of McWhirter's theoretical analysis, we felt obliged to make a careful examination of his reports In the second section of our article we presented a critical analysis based on this examination

We may remark, with entire objectivity, that this examination was undertaken with no animus toward Dr McWhirter or bias against his bold experiment On the contrary, we all had been impressed with the admirable thoroughness of its implementation, and the simple clarity and completeness of his statistical reports More than once, one or other of us actively participated in making an opportunity for Dr McWhirter to present h case However, it is necessary to note that systemat reading of his articles reveals a disquieting characterist in them whenever he had occasion to refer to favourab results obtained with radical mastectomy, he explici imputed " selection " to that series Thus, writing of report of Harrington, he said " Some degree of selectio may be presumed, for in 40% of the cases microscop examination of the axillary glands did not show involv ment " [4] Now it is not obvious why an incidence of 60 with axillary metastasis should imply " selection " I fact, the choice of this statistic as evidence of " selection ' proved an unhappy one, for another paper [7] stated th when radical mastectomy was performed in Edinburg before 1941, the proportion of cases found with axilla metastasis was just 60% The imputation of selection sometimes couched in terms suggesting prejudice, when McWhirter [4] said

> " Unfortunately the extent of failure of the radical operatio is too often concealed by presenting only the results obtaine in highly selected cases By selecting cases for the radica operation very carefully and by publishing the results only i the cases so selected the survival rates may be made to appea so good "

Or again [6]

> " There is no more certain method of securing good result than by careful selection of patients for treatment it is no uncommon to limit the use of a method to early cases and t apply some alternative method in the more advanced cases *Thus as the limitations of radical mastectomy* become mor clearly recognised, it has become customary to restrict th operation to early cases and to refer all the more advance cases for treatment by roentgenotherapy "

The last statement is fairly in reverse of the experience o the Mayo Clinic, where radical mastectomy has been th undeviating basic policy of treatment, and the proportio of patients found inoperable has been in steady decline It appears also to be in contradiction of general experience, as reflected in a recent report from Connecticut,[8] where it was found that use of the radical operation is increasing, radiotherapy decreasing, and the survival-rate improving

In reaching his conclusion that simple mastectomy and irradiation is superior McWhirter did not compare his results with those of contemporary treatment by radical mastectomy He compared them with those of radical mastectomy as practised in Edinburgh before this new treatment policy was instituted The chief part of our critique of McWhirter's report consisted in an analysis of the fallaciousness of this comparison, with its reasoning *post hoc ergo propter hoc* Our own results from the Mayo Clinic over the long period studied, during which there was no material change of treatment, showed progressive improvement So did other results quoted from the literature, and (as could be fairly clearly demonstrated from the admirably detailed statistics given in McWhirter's early reports) the results in Edinburgh also show improvement which was independent of change of treatment As is apparent from independent evidence, this improvement is mainly due to patients coming for treatment earlier in the disease—a result, we believe, of the cancer-education campaign by " lay " organisations Our point here, then, is this McWhirter's claim that simple mastectomy with irradiation is better than radical mastectomy was based on a fallacious demonstration

EDINBURGH AND ROCHESTER

It was natural, however, that we should try to compare our results with those reported by McWhirter We were very conscious that the results in the two series, taken on their face, were not validly comparable. In particular, since we had noted an improvement in our results with time, and since a similar improvement could reasonably be assumed in McWhirter's experience, it would not be "fair" to include results of our experience later than those represented in his report. We segregated our cases in which treatment was given in the same years as those reported by McWhirter—namely, 1941–47. Now what cases of these years should be included? McWhirter often stresses that all cases should be included. But we thought this should mean all cases "coming under treatment within the respective treatment policy". In making comparative studies this is what is generally done, and it seems to be what McWhirter does. In his table v, all the cases (1882) are included, segregated into several groups, but this is a bookkeeping table. In table vi, which is concerned with the influence of age on survival, cases categorised as having distant metastases are omitted. Here McWhirter is proceeding as one normally does—for purposes of comparative analysis one uses only the treated patients. We included only his 1609 cases without distant metastases (1882 less 273 having distant metastases) to represent his series coming under treatment, but of course we included *all* of them. The results in these cases were compared with the results in *all* our cases in which radical mastectomy was performed during the same period, which numbered 1918. It is this comparison that is being brought into question.

---

* The Mayo Foundation, Rochester, Minnesota, is part of the graduate school of the University of Minnesota

We believe this comparison, using only the patients coming under treatment, is the most meaningful one, but in present circumstances we think it to the point to make the comparison including literally all patients—i.e., including McWhirter's 273 patients (15%) who did not come under treatment, and the 362 patients (16%) in the Rochester series found inoperable, that is, patients who did not have a radical mastectomy because of the advanced character of the cancer. There is a mechanical difficulty here, because in Rochester we do not regularly follow up the untreated patients, and so we do not know the number of five-year survivals among them. We made the calculation on the assumption that the survival-rate among these inoperable cases was 4·4%, which is the survival-rate recorded by McWhirter for the comparable 273 cases of his series; we also present the figures assuming that this survival-rate was zero. The results are shown in the accompanying table. Whichever way the comparison is made—for the entire series or for the group representing the treated patients—the conclusion is essentially the same. The five-year survival-rate for the patients dealt with under the policy of radical mastectomy exceeds that for the patients dealt with under the policy of simple mastectomy and irradiation: it exceeds it by what amounts to about 20% of the survivals achieved in Edinburgh. Recalling McWhirter's reiterated emphasis on selection, we may note that in a review[9] of all (i.e., unselected) cases of cancer of the breast in Connecticut in 1941–47, the five-year survival-rate averaged 51·3%; for the Edinburgh series in the same years it was 41·8%.

COMPARISON OF FIVE-YEAR SURVIVALS, TREATED AND TOTAL SERIES

Patients	Edinburgh		Mayo Clinic		
	No	Lived 5 years or more	No	Lived 5 years or more	
		No		No	No
Subjected to treatment policy*	1609	774 (*48·1%*)	1900‡	1127 (*59·3%*)	1127 (*59·3%*)
Not subjected to treatment policy†	273	12 (*4·4%*)	362	16§ (*4·4%*)	0¶ (*0*)
Total	1882	786 (*41·8%*)	2262‡	1143 (*50·5%*)	1127 (*49·8%*)

* In this group, as respects both series, are included the patients used in the original comparison.

† For the Mayo Clinic series these are the patients not receiving radical mastectomy; for McWhirter's series, they are the patients "with distant metastases present".

‡ 19 patients not traced for five years are omitted.

§ Assume 4·4% survived.

‖ Adjustment for hospital death-rate of 0·6% will lower this to 58·9%.

¶ Assume none survived.

Does this establish definitely that radical mastectomy has a higher survival-rate than simple mastectomy with irradiation? In particular can we be certain that the Edinburgh series as a whole, or the group of patients coming under treatment, is not generally of a more advanced cancer? We did not say so. We described the problem of the comparability of cases as "the devil's own question". We carefully considered the data that bore on it, and concluded that the two series could reasonably be regarded as fairly comparable. But in the end we wrote:[1]

> "But when all is said, on this matter of the selectivity of the cases, that can be said, it must be admitted that we really do not know with certainty how important a factor it is in accounting for the difference in survival rates reported in the literature. We agree with Atkins that, in order to evaluate the relative efficacy of radical mastectomy and the projected policy favoring simple mastectomy with radiotherapy, McWhirter missed an opportunity to initiate a controlled clinical trial. . . ."

What is the burden of Dr. Crile's criticism, which is a replica of the criticism made by Dr. McWhirter himself, in some personal communications received before publication of Dr. Crile's letter? In essence it is that the Mayo Clinic cases are favourably selected; specifically it is that we should not have used the total 1609 cases of McWhirter's series as we did. It is suggested that we should, instead, have used only the 1063 cases which he enumerated under the rubric "operable"—which here means operable by radical mastectomy, an operation not performed in Edinburgh. These 1063, however, constitute only 56% of the total 1882 of McWhirter's series,† and it is suggested that they are the ones that should be compared with our 1918 cases treated by radical mastectomy, which constitute 84% of the total 2280 of the Mayo Clinic series (table). This is hardly in keeping with McWhirter's repeated admonitions that, in reporting results, all cases should be included. The 546 cases of his series which he would have us omit on the ground that at the Mayo Clinic they would be regarded as too advanced for radical mastectomy, are enumerated under the rubric "locally advanced"—defined as having "complete fixation of the primary tumour to the pectoral fascia or to the ribs, fixed nodes in the axilla, enlarged supraclavicular nodes or widespread involvement of the cutaneous lymphatics over the breast, but no evidence of more distant metastases "[7]

---

† To accept this suggestion would imply that, among women with mammary cancer who come from South East Scotland to Edinburgh for treatment, the disease is so far advanced that it is "inoperable for radical mastectomy" in 44% of cases. This would be a severe indictment of cancer education in that country in respect of early recognition and treatment, if it does not, instead, imply a conception of inoperability which reflects an extreme prejudice against radical mastectomy. McWhirter's conception of the effectiveness of this operation is clearly given when he says:[4] "When radical surgery is the only method of treatment available and when all cases coming (whether admitted or not) to a large general hospital are considered I do not believe the five-year survival rate will be found to be higher than 20% to 25%." The validity of his estimate may be gauged by contrasting it with the results reported[9] for the general population of Connecticut.

Such definitions are fairly easy to formulate but very difficult to apply in a uniform standard way, even within a single clinic—much less in different institutions in different countries ‡ The indications for radical mastectomy at the Mayo Clinic are very generous, and we believe that we perform this operation regularly with patients who would be placed in the above category In at least one publication[4] McWhirter considered cases of Manchester stage *III* as operable, and such cases comprise about half of those he includes in the category "locally advanced ", though they do not correspond to the quoted definition of this category This will illustrate the element of arbitrariness inherent in deciding which cases are "*inoperable for radical mastectomy*" A proposal[9] to institute an international classification of stages is, in theory, sound But if the classification is to be used for standardising the comparison of survival results, it may in practice introduce more confusion than clarification If method A has a better survival record than method B for all cases, but method B has equal or almost equal results for the cases classified as "operable ", then the general problem of comparability is complicated by the additional problem of applying the classification uniformly If the criteria of "operable " have been defined *in the first instance* by an advocate of B, then the task becomes perplexing indeed It is only human that an advocate of B should think that a particular patient who is not likely to do well by that method would certainly not do well by A Better results with A, except in a controlled experiment, cannot be considered proof that A is really the preferable method to use invariably, many other elements have to be taken into account But the argument that method B's inferior results automatically prove that patients subjected to method A are selected is not acceptable § In our analysis of the Mayo Clinic series, the designation of a case as "inoperable ", *for purposes of computing an inoperability rate*, is not an expression of opinion about its suitability for operation it means that radical mastectomy was not in fact performed Likewise, we did not refer to cases which were "operable " but only to patients who were operated upon by radical mastectomy

The suggestion that our cases should be compared only with the 56% of McWhirter's series enumerated under the rubric "operable " is reminiscent of a procedure occasionally used by physicians, by which a method of therapy is advocated as effective but "only in properly selected cases ' Results are then presented, but only for the properly "selected cases " We do not think this is a good procedure, we think that all patients coming under treatment should be included

The Mayo Clinic series, taken as a whole, may in a sense be considered "selected " The practice of this clinic is, to a considerable degree, a referred one, and patients are referred for treatment from all parts of the country But when local doctors make selection between patients with early or advanced disease, it is those with the more advanced disease and less hopeful outlook who are selected for referral, and our clinic is sometimes dubbed as a "court of last resort " The patients who come for treatment represent a wide spectrum of degrees of advancement of the cancer Early cases do appear, and happily the proportion of patients coming for treatment early in the disease is increasing—a result, we believe, of the cancer educational campaign But very advanced cases are also received, including moribund patients, in no small number, admitted to the hospital only to die there It is necessary to make this rather graceless statement, because in some quarters our results in cancer of the breast are disregarded on the ground that we deal only with "selected " early cases If, because of this misconception, erroneous judgment is made as to the relative efficacy of different methods of treatment, it is the patients who will be the victims

‡ To gauge the difficulty of setting up a *workable* classification of the advancement of disease, even in the relatively objective situation of the reading of X-ray films, one may profitably study an article[8] by Newell, Chamberlain, and Rigler, entitled Descriptive Classification of Pulmonary Shadows

§ McWhirter has presented a semantic case against radical mastectomy which is well-nigh invulnerable He begins with the premise that radical mastectomy *must fail in a large majority* of cases, variously estimated as from 64% to 80%[4 5 7] If now one presents favourable results *with radical mastectomy*, it only makes the case worse for radical mastectomy Because—so the argument goes—since we know that radical mastectomy is an ineffective operation, then favourable results reported with radical mastectomy can be the result only of the surgeon's selecting the early cases and passing on the advanced cases to the röntgenologist for palliative treatment Now the surgeon would not do this if the operation were *effective* Hence, in this argument, good results prove the ineffectiveness of the operation

Occasional Survey

INFECTION ACROSS THE INTACT CONJUNCTIVA

H Stanley Banks
M A, M D Glasg, F R C P, D P H

The mounting evidence that the conjunctiva may be the route of natural infection in certain virus and bacterial diseases seems to have attracted little attention

The first practical application of this concept was in North Africa In 1930 Anderson and Gerard,[1] in a preliminary experiment, instilled convalescent serum into the eyes of 30 contacts of measles three times daily for eight days, and none developed measles during eighteen days of observation, no controls were mentioned and no further report has been traced A few years later Sicart[2] attempted to control an outbreak of measles in a residential school by the method of Anderson and Gerard, but out of 24 contacts treated 11 developed measles As the latter were in the sixth day of the incubation period when the instillations were started, this failure is not surprising

In 1954 Karola Papp[3] put the matter on a more scientific basis She transmitted measles across the intact conjunctiva in 5 out of 6 susceptible children by means of saliva taken from cases of measles in the first three days of the eruption On the other hand, no result was obtained in 9 susceptible children whose buccal mucosa and tonsils were painted with infective measles saliva, and only 2 out of 13 such children developed measles when the infective

---

1 Anderson, C , Gerard F *Arch Inst Pasteur, Tunis*, 1930, 19, 435
2 Sicart, M *ibid* 1936-37, 26, 266
3 Papp, K *Rev Immunol* 1954, 18 380

saliva was instilled into the nose. In all these cases the saliva was well diluted with normal saline With the same technique in mumps 2 positive results in 10 trials were reported, but failure resulted in 6 cases out of 6 when the infective mumps saliva was painted on the buccal mucosa and tonsils Rubella was similarly transmitted across the conjunctiva in 2 cases out of 6, but no success was obtained with chickenpox transmission in 21 instances, both saliva and fluid from vesicles being used None of these instillations produced any local reaction

Papp pointed out that the fine superficial capillary network in the conjunctiva, draining into the deep network by relatively large venous channels, probably favoured absorption of infectious material, in contrast, the capillary network in the nasal mucosa was much coarser, one of its main functions being to warm the inspired air She also suggested that the success of the experiments of Anderson[4] in transmitting rubella by infectious material sprayed into the mouth, might be due to the infection reaching the eyes as well as the mouth

Papp[5] next attempted to prove that the eye was the *sole* route of natural infection in measles In each of three trials, 3 susceptible children, whose eyes were completely protected by goggles closely sealed to the face, were placed in contact with highly infectious cases of measles, and *none of these contacts developed measles* Although this experiment was uncontrolled, the very high infectivity of measles in the early acute stage makes this result indeed remarkable In a second experiment four groups, totalling 18 susceptible children, after exposure to undoubted measles infection, had one drop of convalescent serum instilled into each eye—in 15 cases one to six hours after exposure to the infection, *none of these 15 children developed measles* In the remaining 3 cases, where the instillations were made seventeen to twenty-four hours after exposure, 2 developed modified, and 1 unmodified, measles

This year Rusu[6] has reported strikingly successful results with Papp's method in the prophylaxis of measles, mumps, and chickenpox, when these infections were introduced into a children's sanatorium containing many susceptibles Of 69 children believed to be non-immune, all were protected from measles, as well as 58 from chickenpox in one experiment and 29 in another, and 57 from mumps in one experiment and 61 in another Moreover 12, believed to be susceptible to both mumps and chickenpox, when exposed to both diseases, contracted neither The only failure reported was among 22 children exposed to 2 different cases of chickenpox on successive days, in this group 2 developed chickenpox on the seventeenth day Unfortunately none of these massive experiments were controlled

Relevant controlled experiments in guineapigs have recently been reported by Moore[7] He has produced striking quantitative evidence that the conjunctival route is far more effective than the oral route in producing systemic salmonella infection This finding was confirmed by exposing animals wearing effectively sealed goggles, and also control ungoggled animals, to environments heavily contaminated with *Salmonella enteritidis*, the former were found to be highly resistant to infection, while the ungoggled controls showed high infection-rates It was also found that conjunctival swabbing was more effective than rectal swabs for detecting the spread of this infection, and eye-swabbing combined with segregation of eye-positive guineapigs and their cage-mates was apparently successful in controlling two *Salm enteritidis* epizootics Moore's final remark seems to me to deserve wide publicity "It may well be that the conjunctival route is worth considering in the epidemiology of bacterial and virus infections of man"

Congresses

GENETICS

The Tenth International Congress of Genetics was held in Montreal on Aug 20–27

Population Genetics

T Edward Reed (Ann Arbor, Michigan) discussed the stability of Huntington's chorea It had been suggested that the condition may be increasing as afflicted persons were more than usually fertile This inference was erroneous, and support for it was due to the fallacy of regarding the unaffected siblings as a suitable control Not only would they not know that they would be unaffected at their period of highest fertility, but they would also tend to be younger A comparison of the fertility of persons with Huntington's chorea and the remainder of the population standardised for age showed that the carriers of the gene were not producing children at as high a rate as the remainder of the population of Michigan

Jessica H Lewis and C C Li (Pittsburgh, Pennsylvania) presented data on the families of persons with hæmophilia A and B Type A, which represented 84% of the 116 cases, was the classical hæmophilia, type B was sometimes known as Christmas disease There was strongly suggestive evidence of a disturbed sex ratio, and also a disturbed segregation ratio of the defective gene, in each case the disturbance was such as to increase the dissemination of the harmful gene, and a gene which could load its chance of segregation could be stable although disturbing the viability of its host

Cytology

T T Puck (Denver, Colorado) demonstrated the feasibility of culturing human cells derived from minute skin-biopsy specimens These cells remain in good health for months, and a 20-hour division cycle provides unlimited numbers, the chromosomes retain their individuality, and colchicine inhibition makes their detailed study practicable The elaboration of suitable media should allow chromosomal investigation to be made from material acquired and cultured with the simplicity of a throat swab

Using these methods of culture, J H Tjio (Zaragoza, Spain) and also E H Y Chu and N H Giles (Yale) have made extensive studies of the chromosomal complement in man No cells showing 48 chromosomes were observed In subsequent discussion of these papers J L Hamerton (London, England) suggested that, in view of the consistent preponderance of expert opinion, and the absence of public evidence to the contrary, 46 should be regarded as the basic chromosome number in man Tjio and Chu claim that the individual chromosomes in man can be distinguished, and they have each advanced a separate nomenclature.

B M Slizynski (Edinburgh) presented data on the frequency of chiasmata in the oocytes and spermatocytes of mice, chiasmata are about 15% more frequent in the female, implying a slightly looser linkage

A Bajer and J Bajer-Molé (Cracow, Poland) showed a film of mitosis in living plant cells, including detailed studies of normal mitosis followed by the aberrations induced by irradiation and colchicine The mechanism of mitosis, which is similar in all the higher plants and animals, has not previously been demonstrated at such a standard of technical excellence

Colour-blindness

H Kalmus (London, England) showed a film revealing the world as it looks to the colour-blind The film was made under the direction of a woman colour-blind in one eye

New Individualities of the Blood

Sylvia Lawler (London) presented data confirming the specificity of Gm serum-protein groups in man A Gm-positive serum is defined as that which will inhibit the agglutination of specially sensitised red cells by the serum of patients with rheumatoid arthritis Data from numerous families were consistent with inheritance as a single factor, active in the heterozygote, and not closely linked with other blood-group loci

O Smithies (Toronto) presented an extensive series of two-dimensional starch-gel electrophoretic blocks demonstrating previously unrecognised variation in the constituents of the β-globulin fraction of the plasma While almost all Canadians tested showed only one type (C), a very few having type B also, a high prevalence of type D was found in a sample of Australian aborigines, and some specimens showing this type were obtained from New York Negroes Three alleles are postulated, and these appear to segregate independently of those determining the major blood-groups There is highly suggestive evidence of identity between these β-globulins and transferrin

Blood-groups and Disease

C A Clarke and P M Sheppard (Liverpool) presented their extensive data on the blood-group and secretor status of siblings of patients with duodenal ulcer The increased liability of group-O persons and of non-secretors to duodenal ulcer could not be demonstrated within these family groups The apparent partial protection enjoyed by secretors is unlikely to be a non-specific effect of swallowing polysaccharides, as the quantity in the saliva of non-secretors, estimated by the fucose method, is almost as high as in secretors Specific absorption of ABO antibodies could be demonstrated on the exfoliated duodenal cells of secretors

Clarke and Sheppard also presented extensive data consistent with the hypothesis that the common form of erythroblastosis fœtalis is consequent on a previous pregnancy in which the baby was both rhesus-positive and compatible as a donor to the mother relative to the ABO system

J Buettner-Janusch, S J Behrmann, and F P Thieme (Ann Arbor, Michigan) had studied the ABO blood-group and the secretor status of the saliva and semen, using McNeill's techniques, of apparently sterile men Defining an aberrant secretor as a man not secreting in his semen at least one of the ABO(H) substances present in his saliva, a high proportion of aberrant secretors were found in sterile men, many of whom showed defective spermatogenesis None was found in a sample of fertile men Evidence was also presented suggesting that husband-wife ABO incompatibility may be a cause of infertility or reduced fertility, in the latter case the children included many more of group O than would be expected if the survival of the zygote were unrelated to its blood-group

J A Fraser Roberts (London, England) reviewed work on the associations of blood-group and disease, and presented new data The original claims of an association of the ABO blood-groups with duodenal ulcers, gastric ulcers, and carcinoma of the stomach have been consistently confirmed in so many centres that their reality must be accepted A distinct association on extensive data from one centre had been reported for tumours of the salivary glands, and this could to some extent be regarded as supporting the reality of associations of the ABO groups with carcinomas of the intervening œsophagus, and of the structurally similar pancreas There was also suggestive evidence of an association with diabetes mellitus Fraser Roberts drew particular attention to the inconsistencies between reports on other conditions from various centres Some of these inconsistencies could hardly be fortuitous, and their interpretation, while probably more difficult, might be even more important than that of the clear-cut and consistent associations found in various disorders of the upper alimentary tract

The Uterine Environment

A McLaren and D Michie (London, England) reported that on transplanting fertilised mouse ova into a foster-mother there was clear evidence that the number of lumbar vertebræ in the embryo tended to resemble that of the foster-mother more closely than that of either parent The stage at which segmentation is determined excludes any simple mechanical or nutritional explanation

K -H Degenhardt (Munster, Germany) demonstrated the consequences of exposing rabbits to an oxygen tension equivalent to that at 28,000 feet for four hours on the 9th day of pregnancy A primary disturbance of the cell metabolism of the notochord predisposes to a generalised disturbance of the central nervous system and its surroundings somewhat similar to those found in anencephaly in man

Dorothy Warburton (Montreal) presented data on the factors influencing the spontaneous-abortion rate in man. The incidence in relation to a history of previous abortion varied smoothly between 14% in women who had not previously aborted and 26% in women who had had three previous spontaneous abortions In relation to maternal age there was a smooth increase from an incidence of 12% in women under 25 years to 23% in women aged 40–44 years A history of prematurity of previous infants appeared to be associated with an increased risk of abortion Congenital deformities did not appear to be associated with a difference in incidence of abortion of other pregnancies, with the exception of cleft palate which was associated with a distinctly lower abortion-rate No increased risk could be demonstrated in consanguineous marriages

Familial Concentrations of Joint Disease

M Whittingill, E H Hendricks, G S Taylor, and L S Thorpe (Chapel Hill, North Carolina) demonstrated a vast single pedigree involving 3000 persons with special reference to the distribution of rheumatoid arthritis, Still's disease, and spondylitis Within the family as a whole the incidence of these diseases was comparable to that in the general population, but there was a definite several-fold increase in incidence in close relatives of affected persons While relatives of cases of rheumatoid arthritis were particularly prone to rheumatoid arthritis, and relatives of cases of spondylitis were particularly prone to spondylitis, there was no tendency for relatives with one disease to be predisposed to the other All fourteen cases of Still's disease were found in parts of the family unaffected by rheumatoid arthritis, and most were in close relatives of patients with spondylitis Consanguinity also appeared to predispose to this disease A remarkable but possibly fortuitous finding was that 14 cases of harelip were found, all in parts of the family unaffected by rheumatoid arthritis

Detection of Carriers of Recessive Genes

D Y-Y Hsai, S G Driscoll, and E M S Gawronska (Chicago) discussed the advantages of being able to discriminate the heterozygous carriers of recessive genes In phenylketonuria the estimation of the tyrosine-phenylalanine ratio allowed almost complete discrimination between these carriers and the normal heterozygote In cystic fibrosis of the pancreas the sodium content of the sweat, although intermediate between that of the two homozygotes, was too variable to allow reliable discrimination In the much rarer conditions of galactosæmia and von Gierke's disease evidence of impaired enzymic activity could be demonstrated in blood from most known heterozygotes, but this was not, at present, reliable as a method of discriminating carriers outside affected families

H Harris and E B Robson (London, England) presented extensive data on the families of patients with hypophosphatasia Urinary chromotography showed that the majority of presumptive heterozygotes could be detected by their excretion of ethanolamine phosphate, while this metabolite could not be detected in a large series of controls The proportion of heterozygotes excreting this varied greatly between different families

Influence of Radiation in Man

H J Muller and T Dobzhansky, approaching the problems of the atomic age from their diverse theoretical standpoints, urgently drew attention to the future implications of diagnostic, industrial, and military irresponsibility—a theme later incorporated in a resolution by the congress as a whole Muller's interpretation of the hazards to be anticipated is that the general viability of the entire race will suffer, the main effect being on the vigour and longevity of adults Dobzhansky, also arguing by analogies predominantly derived from the fruit-fly, sees no likelihood of any generalised impairment of health and bases his anxieties on the moral problem that the dissemination of atomic waste is largely in the hands of men who are prepared to expose the unborn to the unknown There appears to be no informed doubt that the unborn have been, and will be, irretrievably exposed to the risks of recessively determined diseases on a scale previously associated with the execution rather than the preparation of war While the numbers are large the proportions are so small that, even at the sites of the atomic bombs used in war, only in rice has unexceptionable evidence of unequivocal genetic change been demonstrated

Medicine and the Law

Press Publicity before Trial

WHEN a criminal charge comes before the magistrates, it may be dealt with summarily that is, the magistrates will decide whether the accused is guilty or not, and, if they find him guilty, decide upon sentence In serious cases, however, the magistrates perform a different function They decide whether there is a prima-facie case against the accused, and, if so, they commit him for trial before a jury at assizes or sessions The magistrates have power to sit privately when doing this, but they nearly always sit in public, and the press can report the case fully

Committal proceedings before the magistrates have not always been held in public Before the days of organised police forces, the magistrates had the responsibility of arresting offenders, and, in deciding whether or not to commit for trial, they were also in effect performing a function now normally undertaken by the police—namely, deciding whether the accused should be charged at all But, for the past hundred years or so, committal proceedings have nearly always been heard in public, and this has been felt to be in the best traditions of British justice

There is a risk, however, that disclosures in the magistrates' court may prejudice the trial before the jury Evidence may be brought before the magistrates, and widely reported, which is not in fact used at the trial This happened in last year's trial of Dr John Bodkin Adams Before the magistrates, the prosecution led evidence of the circumstances in which two other patients had died, this evidence was not given at the trial Moreover, there is some unfairness to the accused in that he may, quite properly, decide to reserve his defence—with the result that the press can report only the prosecution's case before the magistrates Even if this does not attract such nation-wide publicity as that given to the Adams case and some others, a jury may be prejudiced by what they have read in a local paper

After the Adams trial, the Lord Chancellor appointed a committee, with Lord Tucker as chairman, to consider possible remedies[1] This committee is firmly against extending the number of hearings in private It regards this as undesirable and unnecessary because the same end can be reached by restrictions on the right to report The committee recommends that, unless the accused has been discharged, or until the trial is over, any report of committal proceedings should be limited to particulars of the name of the accused, the charge, the decision of the court, and similar facts This recommendation cannot be put into practice without legislation

In England Now

A Running Commentary by Peripatetic Correspondents

IN a little over two years I shall be 65, and Parliament has decreed that I shall be unfit by reason of age to treat patients in the Health Service and to teach medical students I propose then to go to the bar, and "with a little bit of luck" I hope to become Lord Chief Justice in my early 70s I may—but I make no promises—retire from that post when I am 81, but if I do I shall continue to sit as a judge in the Privy Council and the House of Lords, where, of course, I shall also help to make the laws—such as that one about consultants retiring at 65

* * *

The path through Blossom Wood is vanishing When we came, three years ago, it was not uncommon to see small parties of people wandering along it as it cut diagonally across the hanger beyond the stream at the foot of our garden Sometimes they came from a picnicking car left where the path begins as a track higher up the lane sometimes they were locals on a Sunday afternoon stroll or children lured by the bluebells in spring or the stately summer foxgloves Last year there were fewer and now only a man with a gun is rarely seen

Though it is a bridle-path marked on the official parish map, the farmer has wired up the far end to prevent his cattle straying into the wood, where one broke a leg recently—it is easier and cheaper than putting a stile or a gate But the real reason for its rapid decay is Ted's purchase of a motor-bike on the never-never Twice a day he used to walk along it to and from his work, and that was enough to keep it clear without conscious effort on anyone's part Now the brambles spread across like thin green snakes, in places the bracken was shoulder-high this lush year, and in the little central groove where there used to be hoof-marks the young alders and birches are two feet tall and more I have just spent a hard morning clearing my favourite part, from where the path from the ford in our garden joins it to the sunlit clearing where a great spotted woodpecker often clings in his uniform of black, white, and red like the Kaiser's flag But I know it's a hopeless battle since Ted got his motor-bike

* * *

As we had been given the tickets, my wife and I were determined to visit the flower show I hurried through my morning clinic and we set off Our enthusiasm was slightly damped by the half-mile walk from the car park, the crowds of people, and the sultry, thundery weather However, we went straight to the Grand Marquee for Non-competitive Trade Entries and forced ourselves towards the Rose Display by the well-known technique of accusing mythical people behind you of pushing you rudely forwards Hardly had I arrived at my goal and begun to write down the names of next year's purchases when the loud-speaker stopped its "No smoking" requests and said, "Will any doctor in the grand marquee please go to the ambulance tent at once" Reluctantly and with even greater difficulty I forced my way out, and, asking my wife to wait at the marquee entrance, went to the ambulance tent

A very large and elderly lady had collapsed with substernal pain She said that she was subject to heart attacks for which she took tablets, but that, as she had wanted a day off, a really good outing, and a complete change, she had left the tablets at home The St John Ambulance Brigade and I undid her corsets and I applied my ear to the lower part of her sternum Both heart and bowel sounds were loud, clear, regular, and unhurried I straightened my back and considered the next step At this critical moment, to my relief, another, obviously professional, figure entered the tent "Ah, a proper doctor, I see," I said, "I am only an orthopædic surgeon, I am sure this lady will receive better advice from you than from me" "I am sorry, I am only a medical officer of health," was the answer We consulted together and decided that the interests of the majority of those present in the tent would be served best if she was taken by ambulance to the casualty department of the local infirmary

---

[1] Report of the Departmental Committee on Proceedings Before Examining Justices Cmd 479 H M Stationery Office, 1958

Needless to say, my wife was no longer at the marquee entrance When we did meet, some time later, it was obviously hopeless to try to enter any of the marquees, so we consoled ourselves with the sundries section By the time I had bought several garden chairs, tables, and other horticultural aids I realised that it had been an expensive consultation

* * *

In these days of highly specialised anæsthesia when it is so easy to attribute difficulty to some misbehaviour of the flowmeter or to some atypical activity at the end-plates, it is strange to look back to the days when the man dozing at the head of the table took some responsibility for things going wrong I shall always look back with pleasure to the day when I worked with a Hibernian anæsthetist who had all the charm of his race If I said "is there a little congestion?", he would promptly reply "Yes, indade, she's absolutely purrrple" Or if I asked "Is she straining a little?", he would reply "Yes, she's as harrd as a boarrd"

* * *

Seated one day at the Dog Show, I was weary and ill at ease until I overheard two ladies discussing their doctors In readiness for the day when such doctor-fanciers hold doctor-shows at which they will walk their favourite practitioners round in a large circle—instead of, as at present, running them round in small ones—I offer a basic classification of the zoological genus *Medicus*

1 *M hocuspocus* (or Quackshund)—a common wild (*non-registered*) species, developed from Barbary corsair blood-lines

2 *M familiaris*—a well-broken species including such types as *M geepee debilitatus* (Bevan) or *M spina professionis*, according to who's talking This type belongs to the great working group of *Medicus* and is of great utilitarian value, being used as draught animals, distributors of susstificates, herders of livestock (which are rounded up with great alacrity), and guide-animals for the socially inadequate *M geepee deb* (Bevan) hunts singly or in small packs, ranging rapidly about a terrain which it most jealously preserves

Good points are long pendulous ears (for meshing with stethoscopes), powerful and free-acting hind legs, long memories, thick skins, and poor appetites Attempts to deepen the purse of this type have been unsuccessful Coats range from hairless to long-haired varieties Common colours are white, livery, puce-magenta, grey grizzled, and tartan These animals prefer fur-bearing well-heeled prey and have the temperament, size, and intelligence to qualify as household pets

Individual breeds of *M familiaris* include *M chirurgus*, a sporting type from retriever blood-lines, pursuing fur- (mink for choice) *bearing* prey *which it flushes out very thoroughly* *M chirurgus* works best in excavations, orifices, and cavities Usual colours are white, white mask with rufous muzzle, prominent abdomen, and alert expression For these animals to kill prey is a disadvantage

And now if you fellow dogsbodies will excuse me I have to see a patient about a condition powder

* * *

"They fool me to the top of my bent" Thus, with Hamlet, must be thinking the ghost of the illustrious Emile Coude His grandnephew, M Hercule Coudé, has done us service in keeping his name to the fore, but, alas, he falls into the popular error of attributing the straight catheter to M Jaques

It is natural to associate catheters with the French, but in this case the catheter is English Its date of origin is unknown, but it was widely used in the 18th century when, for obvious reasons, it was known simply as "the jakes" In the Victorian era feelings against the name ran high, and it was impossible to move in urological circles without becoming involved in heated arguments The climax was reached at a certain meeting when it was decided to consign the jakes to oblivion This so affected a French visitor that he leapt to his feet with the now famous ejaculation "Eurethra!" Called to the rostrum, this man, M Jaques, gave an impassioned speech in which he implored the audience to consider the patient before any matter of prudery He saved the day, and since then the spelling of the catheter has been "Jaques"

Letters to the Editor

CHILDREN IN HOSPITAL

SIR,—If a child is suddenly whisked away from home with, say, acute appendicitis, daily visiting is undoubtedly a great advantage The patient is likely to be ill and in pain and everything happens too quickly for him to be able to adjust himself Not so in a long-term hospital Here the patient's stay is of many weeks or months, he has time to reorientate himself and learns to make the hospital his temporary home Patients in such hospitals are always drawn from a wide area and visiting is expensive both in time and in money

Because the patients are usually well and because they are in hospital a long time, orthopædic hospitals have always been cheerful and rather unconventional places At this hospital there are school lessons and cinema shows, birthday teas on the lawn, and a Boy Scout troop, and the child feels that he is a member of a community much, I suppose, as a child who has been sent to boarding school

All this has been pointed out before, and in a number of long-stay hospitals with whom I have been in touch the introduction of frequent visiting has been resisted by the senior staff Yet, because of the propaganda by psychiatrists and psychiatrically minded pædiatricians, the Ministry of Health has more or less forced us to increase visiting from one to three days per week, and pressure is now being exerted to introduce daily visiting

This propaganda is being backed up by a film *A Two-year-old Goes to Hospital* I am unimpressed by it as a serious argument in a serious discussion Ever since the days of Al Jolson, audiences have been moved to tears by the pathetic appearance of a small child looking sadly through the bars of a cot Only then, if I remember rightly, the child was looking accusingly not at an ogre of a Matron but at Daddy who was not visiting Sonny Boy any longer because he and Mummy could not get on together Let me be careful in what I say If on the day of admission and under the immediate impact of the separation we asked our mothers whether they wanted daily visiting or not, a number would probably opt for it But soon they find to their amazement that the children are settling down perfectly well It is a tragedy to develop a tuberculous hip, but, properly handled, even a boy of five can adjust himself to such a situation, can understand that he is in hospital because he has a poorly leg and that his mother will visit him on Sunday Again, let me admit that there are exceptions and it is the child of 18 months or so who is most likely to find difficulties This is the awkward age when one is old enough to worry about one's surroundings but not quite old enough to understand Recently we had such a little girl in with poliomyelitis, she settled badly, was bewildered and withdrawn Because she was difficult I arranged for the mother to call in every day, to go with the child to the massage department, to sit by the bed side when I did my ward rounds The response was good, and when the mother called on me a fortnight later we agreed that things had improved a good deal The question she then asked me was typical Not "I hope you will nevertheless not withdraw the privilege of daily visiting", but "do I still have to come every day ?"

When the three visiting days per week were introduced at this hospital I wrote a circular letter to the parents which was handed out on a certain Sunday afternoon at 2 o'clock At 2 10 there was a knock at the office door and one of the sisters asked me to come to her ward "There is almost a riot on, Sir" was the report I went and found myself surrounded by mothers who wanted to know what "all this is about" They asked when were they to do their *shopping*? Who, they wondered, was going to get the tea ready for their husbands coming home from work? I told them that this was only a permission to visit, that they did not *have* to come every time if they were busy, but they looked through that argument at once If there was no visiting, they said, their child would not miss them, but if there was he would feel neglected unless they came. And so they come, or arrange for Granny to come, and even pay neighbours to visit their child so that he should not feel neglected on visiting day Travelling as much as three hours here, and three hours back, summer and winter, for months and months

However this question goes further It has been said by psychiatrists that the separation of a child from his mother causes severe, lasting psychological damage That there is a direct connection between it and such things as juvenile delinquency, and long-stay orthopædic hospitals have been singled out for blame in this matter This is not our experience at all Orthopædic surgeons who work with these crippled children find that they grow up into perfectly well adjusted adults and good citizens In the ordinary run of fracture-clinic patients they stand out because of their quiet, non-complaining behaviour Far from being bitter their suffering has made them considerate of others Dare one suggest that sometimes difficulties, properly met, ennoble the character?

Permit me, Sir, to end with a letter I received a few days ago from a farmer's wife in Derbyshire. It concerns a boy of 6 who had poliomyelitis and who is to come into hospital for an operation

"Dear Doctor, I am sorry to say John's sister broke-out in German Measles today, there is only John who has not had them now So all being well I will write again on the 26th of August and let you know how things are. John is very disappointed he is unable to come to the hospital yet, as he is looking forward to coming very much I, John's mother, had German Measles three weeks ago Yours truly Mrs X."

King Edward VII Orthopædic Hospital,
Sheffield
E G HERZOG

SIR,—Professor Illingworth's thoughtful lecture (July 26) and your own forthright leading article have evoked replies which by their vehemence cloud the main issues and exaggerate the minor ones

No one will deny that the larger infectious-diseases hospitals situated in and serving a heavily populated area provide an essential and efficient infectious-diseases service

A different picture is presented by many of the smaller infectious-diseases hospitals, some of which do not have a resident medical officer, and where clinical-laboratory and radiological facilities are absent or rudimentary Admissions are sometimes accepted by nursing staff or even clerks The term "infectious" is interpreted in its widest sense A consultant in infectious diseases, at his main hospital 15-20 miles away, cannot hope to provide adequate supervision of urgent cases

A clinical laboratory is as essential in the treatment of meningitis as an operating-theatre is in the treatment of acute appendicitis No-one would consider admitting a case of appendicitis to a hospital without a theatre constantly staffed Cases of meningitis are admitted to these small infectious-diseases hospitals with little or no laboratory facilities

The Ministry's approach to this important matter is difficult to understand They have suggested, and it is widely accepted, that infectious blocks should be included within the curtilage of all new general hospitals The present central infectious hospitals would, of course, continue to provide for local needs and for cases from further afield which, because of their complexity or epidemiological character, require the specialised skill and equipment only available at such hospitals It comes, therefore, as a surprise to learn that the plans for the new Huddersfield General Hospital of 600 beds, one of the first in the country, do not provide for an infectious block This would seem to be a retrograde step, more especially as it may create a precedent

Dr Breen (Aug 16) is seriously misinformed when he states that pædiatricians "have wrought so well as to imperil their own survival" He presumably bases this statement on the prevalent misconception that the amount of work done in a specialty depends on the number of beds allocated A careful analysis of the figures will show, broadly speaking, that in those areas where the number of pædiatric beds has fallen by a half over the past five to ten years, the number of outpatients have practically doubled It is generally accepted that outpatients are by far the most responsible and onerous part of a physician's work, a burden that the infectious-diseases consultant is very largely spared New pædiatric appointments are being made and old appointments split It is noteworthy that between 1934 and 1956 in the U S A the number of pædiatricians has quadrupled, while in the same time the total of physicians has increased by only a third Such an increase is exceptional, but the trend is obvious in other countries as well.

Halifax General Hospital
W P SWEETNAM

SIR,—Professor Illingworth's lecture and your leading article raise a number of points involving fever hospitals

These hospitals have long since discontinued routine admission of uncomplicated scarlet fever and measles On the other hand, pneumonia is a notifiable infectious disease, while "meningitis" may include a variety of conditions, some notifiable such as cerebrospinal fever and, sometimes, poliomyelitis It is therefore both logical and safer to send these cases to fever hospitals, whose senior consultants, incidentally, have an unrivalled experience of these infections—not to mention gastroenteritis

Professor Illingworth decries the efficacy of cubicles in the prevention of cross-infection, and while this may in some instances be true—gastroenteritis due to *Escherichia coli*, for example—the successful segregation of all types of infectious diseases alongside each other has been carried out for years in fever hospitals The reason for trouble in other types of hospital, even with cubicles, may well be failure to apply efficiently the approved techniques of fever nursing—a potent argument for the retention of this particular training

Undoubtedly, many pædiatricians have had extensive experience of infectious diseases, but this can hardly be universal There is surely some arrogance in claims that the age of the patient rather than the physician's experience of the diseases concerned should determine who is to look after him If pædiatricians are so anxious to assume control of infectious diseases, they should at least make it compulsory for their trainees to serve an apprenticeship, preferably as residents in fever hospitals

An alternative solution for the main fever hospitals, which had the blessing of the Royal College of Physicians, is that they should be run by general physicians with a primary interest in infectious diseases This is in practice very frequently the case, in fact if not in name Surplus beds, if any, can then more easily be devoted to general medicine rather than pædiatrics, and staffed where necessary with the help of outside consultants These beds could readily be switched back to fevers in the event of an epidemic The continuity of medical administration, inseparable from fever practice, still intimately linked with the public-health service and based on long experience, would be preserved. The disruption of attached special units, such as those for poliomyelitis or tuberculous meningitis, into separate age-categories, a process wasteful of medical experience and efficiency, as well as of physical resources and money, would be avoided

Have the pædiatricians given due thought to the public-health aspects of the case, and to what medical officers of health think?

Hoylake, Cheshire J L FLUKER

SIR,—Since the publication of Dr Lawson's letter (Aug 23), I have heard from Mr A G Linfield, chairman of the South West Metropolitan Regional Hospital Board, and I gladly accept his assurance that it was not his intention, at the interview which we had, together with Major-General Hawes, on July 23, to convey to me the impression that the board were in any way committed by *the Ministry's suggestion to close Queen Mary's as a* general children's hospital

Queen Mary's
Hospital for Children,
Carshalton, Surrey

H J WELLS
Chairman of Management Committee

APPROVED NAMES

SIR,—The interim report of the Committee on Cost of Prescribing contains various criticisms of the approved names which the General Medical Council publishes on the advice of the British Pharmacopœia Commission The commission was not advised by the committee that it proposed to discuss approved names, but had this intention been known the commission would have wished to furnish evidence for the committee's information, thereby avoiding the many inaccuracies which appear in the report The commission regrets that they were not invited to appear before the committee

The commission now offers the following observations on some of the statements which appear in the report

1 The report states (para 41) "There are for example just under 5000 *proprietary preparations available for prescribing* Economies would follow, we believe, if simple approved names *for new products could be evolved quickly* and given the widest possible publicity"

In the majority of cases the provision of an approved name has no effect on the price of preparations The issue of the simple approved name primidone for the product 'Mysoline' has had no effect on the price of the drug—to quote only one of numerous possible examples

2 *The committee states in* para 42 of the report that "We are informed, for example, that the present rules of nomenclature require that the approved name should be based on a drug's chemical constitution"

This statement is erroneous The guiding principles used in selecting or devising approved names do not impose an inflexible style and it will be seen that many names are not based on the drug's chemical constitution—e g, most antibiotics, warfarin, azovan blue, gallamine, lignocaine, macrogol, mustine, sulphan blue Among these guiding principles are the following

> "An attempt should first be made to form a name by the combination of letters or syllables from the systematic chemical name
>
> Cognisance should be taken of the names of closely related substances and where desirable the name should reflect this relationship
>
> The names should be distinctive in sound and spelling and should not be liable to confusion with names already in use
>
> Names which are difficult to pronounce or remember should be avoided
>
> Names used in the *United States Pharmacopœia*, *New and Nonofficial Remedies* (Drugs), and international non-proprietary names should receive preferential consideration"

In giving preferential consideration to existing non-proprietary names, and so avoiding the international *confusion which* may arise if a second name is adopted for the same drug, the commission has found it preferable *in some instances to accept* such a name in spite of its defects For example, the names chlorotrianisene, diphenylpyraline, and tripelennamine were issued by the American Medical Association and widely used before the drugs were sold in Britain Although the commission was critical of these names, the balance of advantage lay in accepting them as approved names

3 The report states (para 43) that "At present a year or two may elapse before an approved name is formulated for a new drug During this period doctors get into the habit of prescribing the new preparations by their trade names "

It is exceptional for a long period to elapse between the appearance of a new drug on the English market and the publication of an approved name Approved names for new drugs of English origin are usually available by the time the drug is placed on sale and indeed the approved name is generally available before the drug is distributed

During the past five years, nearly 60,000 copies of lists of approved names have been circulated by the commission, but *wide advertisement is the most potent factor in establishing* the names of medicinal products and it is manifestly not a function of the commission to advertise approved names in the manner or on the scale adopted for trade names Copies of supplementary lists of approved names are supplied to some hundreds of correspondents at home and abroad and they are published in many professional journals

4 The committee states in para 46 of its report that "We consider also that before putting a new drug on the market manufacturers should be encouraged to ask the British Pharmacopœia Commission to give it an approved name As soon as that has been done the approved name should appear on labels and advertising literature for proprietary preparations as prominently as the trade one"

Over many years it has been the practice of most British manufacturers to approach the commission for an approved name for a new drug before placing it on the market For such products the approved name is usually available whilst the substance is undergoing trials and before it is generally released for sale The commission has no control over the manner in which approved names are used by *manufacturers* on labels and in advertising literature

5 The committee expresses the opinion (para 44) that "some of the principles of nomenclature now in force may well be inappropriate today", and recommends that the commission be asked to review these principles It is difficult to comply with this request unless a more specific statement is provided

The report makes no reference to a number of important considerations that apply in the selection of approved names, such as the international aspects including the non-proprietary names issued by the World Health Organisation, and by the American Medical Association for many drugs that appear in England only after a period of use in the United States Indeed most drugs introduced on the English market have had a period of use in the United States or elsewhere in association with a non-proprietary name, and unless over-riding considerations apply it is undesirable to coin a second non-proprietary name even when the established name falls short of the commission's desideratum Approved names are applied not only, *and perhaps not primarily*, in the writing of prescriptions but also in scientific articles appearing in journals with world-wide readership, *for reference purposes*, and in the labelling of products in accordance with legal requirements including purchase-tax and poisons regulations Approved names are also of great value in indicating to prescribers and pharmacists that the same drug is being described under more than one trade name

Attention is also drawn to the problems which arise in relation to existing names especially those registered as trade marks. It has been a frequent experience that a proposal for what would appear to be an admirable short name must be discarded in favour of a more complicated one because, on the authoritative advice received by the commission from the Patent Office, the short name is held to conflict with a trade mark registered in this country.

The commission offers this statement in the hope that it may dispel any misunderstanding which the report may have created, and that it may help towards a better appreciation of the origins and purposes of approved names.

MIDGET ANÆSTHETIC MACHINES

SIR,—In your annotation of Aug. 16 you draw attention to the development of two midget anæsthetic machines which depend on a non-explosive cyclopropane mixture to give but a few minutes' anæsthesia.

I have long felt that there might be a place for a really portable apparatus capable of producing anæsthesia of one to two hours' duration, for possible use in the Services, major disasters, industrial accidents, shipping and air lines, &c., and with this end in view I have adapted an existing lightweight oxygen therapy unit into a halothane/oxygen closed-circuit anæsthetic machine with various refillable or "throw-away" components. This apparatus is still in process of manufacture, testing, and calibration.

Southlands Hospital,
Shoreham-by-Sea.

P. J. C. BURTON.

ANATOMY OF THE CARDIA

SIR,—Some of the conclusions endorsed in your leading article of Aug. 16 are still controversial.

In particular, the opinion of Atkinson et al.[1] that a raised pressure zone in the lower œsophagus immediately above a hiatus hernia signifies the activity of a "sphincteric barrier" is open to criticism. Jennings[2] in his review of this paper has already pointed out that in such cases the recording tube, as a foreign body, might well cause sustained contractions of the lower œsophagus.

Undoubtedly the œsophagus immediately above the œsophagogastric junction exhibits particular properties of distensibility and contraction, sufficient to be designated the "gastroœsophageal segment of expulsion" by Lerche,[3] but this does not necessarily imply that it serves to prevent reflux. It may chiefly be concerned with forward propulsion after swallowing, by contraction of the segment as a whole, analogous to the distal pyloric antrum.

Several investigators have mentioned the apparent weakness of this "pressure barrier".[4–6] Wolf et al. believe that the terminal œsophageal segment is so easily ballooned out that it constitutes part of the hernial pouch, the junction appearing in cineradiographs as a shallow horizontal groove. Actual invagination of the distal œsophagus in hiatus hernia has been reported by Kleinfelter.[7]

The area from which Atkinson et al.'s pressure recordings were taken, therefore, may have been the distal 1-3 cm. of the "tubular" œsophagus and not the most distal segment. In radiographs this former region often appears narrowed for several centimetres, and it may be more irritable than normal because of œsophagitis.

The observation that delay in passage of barium through the œsophagogastric junction can be abolished by continuous drinking of barium, as distinct from individual swallows, does not prove that they are different physiological processes, as Creamer and Pierce would have us believe. The build-up of pressure by rapid passage of a heavy liquid such as barium might be sufficient to obliterate this weak "sphincter" zone.

In spite of the inability of Atkinson et al. to demonstrate a change of pressure where the hernial neck passes through the hiatus, the fact remains that in a large proportion of cases the radiologist is unable to fill the hernia by reflux from the stomach (Flood and Hennig,[8] for example, report reflux in 31 out of 70 cases, many having repeated examinations.) Wolf et al. observe that the site at which reflux is most often obstructed is at the level of the hiatus—i.e., the mechanism is extrinsic. Presumably this functions effectively during the examination and at other times, but at night, particularly when a low tone in the crus combines with the supine position, reflex occurs.

In my limited radiological experience I have found no correlation between the presence or absence of reflux symptoms and the extent to which radiological reflux takes place—i.e., whether only the hernial pouch is filled or the whole œsophagus.

HÆMOPHILIA-LIKE STATES IN GIRLS

SIR,—Dr. C. Merskey (Aug. 2) has commented on the omission in our paper[9] of the family first reported by Treves[10] in 1886 and re-studied by him in 1950.[11] This family was not discussed because of the atypical hereditary pattern.

In the first four generations the disease was reported to have been transmitted from father to son, which does not occur in classical hæmophilia. We, of course, cannot judge the validity of these early reports. We were impressed by the apparent severity of the bleeding state in the members of this family, despite the fact that their clotting-times were only slightly prolonged. In both true hæmophilia and Christmas disease, it is uncommon to find permanent ankylosis of joints in patients whose clotting-times are only one or two minutes above normal.

The unequivocal diagnosis of classical hæmophilia can only be made if the typical hereditary pattern is obtainable, if the bleeding and prothrombin times are normal, and if the absence of the specific factor, thromboplastinogen (antihæmophilic globulin), can be established with certainty. The coagulation defect of the girl we reported is, according to all the tests now available, identical with that of true hæmophilia, nevertheless, the diagnosis of classical hæmophilia cannot be made because of the absence of a hereditary history. The bleeding condition in one of a pair of identical twins which Dr. Conway and I reported[12] also corresponded closely to classical hæmophilia, but again the diagnosis could not be made with certainty because of the atypical hereditary pattern.

The question arises as to what determines the basis for applying the term "hæmophilia". If it is the characteristic hereditary pattern, then Christmas disease or P.T.C. deficiency can justifiably be called hæmophilia B. If,

COUDÉ STRAIGHTENED OUT

SIR,—As the author of the article on Coudé mentioned by Mr Hamilton Bailey and others (Aug 23), I feel that to call the article a " deception " or " hoax " is unfair None of the Cardiff students did anything to bring the article to the attention of anyone connected with *A Short Practice of Surgery* Coudé is something of a standing joke in Cardiff, and nobody really believed in him

I have not yet given up all hope of revising our knowledge of medical history I am now doing some research about Pyogenes, an Ancient Greek who postulated the existence of the staphylococcus many years before the microscope was invented I hope that before long he will achieve his fair share of fame, in the form of a footnote in our most popular textbook on bacteriology

Morriston Hospital,
Swansea.
RAPHAEL PASH

THE WAALER-ROSE FACTOR IN RHEUMATOID ARTHRITIS

SIR,—I have not been able to satisfy myself that my arthritic patients will be helped by the knowledge that their serum may potentiate the agglutination of sheep cells sensitised with rabbit amboceptor [1] I shall comfort myself with the words of Broussais [2] " Facts which cannot be used for healing do not belong to the physician, they belong to the naturalist " This test is based on the gospel that rheumatoid arthritis is an entity, separate and distinct from all other diseases But Clifford Allbutt [3] said in 1866 " We are now but awakening from the metaphysical delusion that diseases are separate entities " Poynton [4] wrote of the rheumatic disorders as " allied disorders [with] strange likenesses as well as strange differences For the student it is easier and more helpful to define differences, but for the expert it is often of service to study similarities "

In our present state of ignorance of its causation, such terms as rheumatoid arthritis can only be tentative A word like " rheumatoid " can be used as we use " carcinoma " to signify a real change in the tissues Then it must be applicable to monoarthritis and the infective forms of arthritis as well as to polyarthritis Or we can use rheumatoid in its popular sense, as a convenient term like scrofula and dropsy It is purely tentative and at the next advance in knowledge may be swept away At present there is a danger that knowledge be suppressed by insisting too much on a " diagnosis " as the basis for the discussion of any rheumatic patient's symptoms

Not one of the fifty or so extant classifications of rheumatism can include more than 60% of all cases [5] [6] Cobb [7] was unable to fit more than one-eighth of 372 rheumatic patients comfortably into any of the standard categories Mainland [8] has also shown how unworkable are all attempts to classify rheumatism

Much of the present confusion in rheumatology is due to superstitious belief in the ancient terms, acute and chronic, and has arisen because our desire to classify has outrun our knowledge If we are guided by superficial appearances only, we shall be like the two boys who were asked to grade a sack of apples Not knowing that there existed real differences between the apples (Rome Beauties, Jonathans, &c), one graded his half into large apples and small apples, while the other also had two heaps, red apples and green apples Needless to say, in both lots there were many intermediate and unclassifiable types

H PULLAR-STRECKER

TOBACCO AMBLYOPIA

SIR,—The interesting article by Dr Heaton and his colleagues in your issue of Aug 9 mentions the low serum-vitamin-B_{12} levels in vegans, who, because they consume no animal food, tend to develop a dietary deficiency of vitamin B_{12} and therefore may provide valuable information on this subject

My colleagues and I in our investigations on vegan non-smokers have found their low serum-B_{12} levels to be associated with an increased urinary excretion of thiocyanate [1] which could be reduced by oral or parenteral administration of vitamin B_{12} [2] In a communication [3] to the Fourth International Congress of Biochemistry in Vienna, we propose to show that in non-vegan smokers there is also an increase in the urinary excretion of thiocyanate roughly proportional to the degree of smoking and parallel with the increase in serum-thiocyanate recently found by Stoa [4] in smokers This increase in thiocyanate excretion may occur also in " stress " conditions such as menstruation, pregnancy, or lactation *when there is an increased requirement* for vitamin B_{12} It may have a bearing on the suggestion of Heaton et al that the beneficial effects of vitamin B_{12} on tobacco amblyopia are due to its making good a *deficient* intake of the vitamin Vegans who are subject to such a deficiency are usually non-smokers However " eye trouble ", which is now being investigated, has been encountered in a life vegetarian (living on an almost vegan diet) after she had *voluntarily taken up extensive smoking for some time*, and greatly increased her urinary excretion of thiocyanate

Thiocyanate is formed in the body by the action of the liver enzyme rhodanese on cyanide [5] After administration of ^{14}C-labelled cyanide to dogs most of the radioactivity has appeared as $S^{14}CN$ in the urine [6] It therefore seems logical to assume that an increase in thiocyanate excretion during smoking would be caused by any cyanide derived from the tobacco Tobacco smoke has been shown to contain cyanide in amounts of the order to be expected if the increase of 5–20 mg in the daily thiocyanate excretion in smokers were due to cyanide inhaled in the tobacco smoke [7]

These findings indicate that it would be of interest to study the cyanide and thiocyanate metabolism in tobacco amblyopia

There might be expected to be a high rate of urinary excretion of thiocyanate, which would be decreased by administration of vitamin B_{12}, and the rate of decrease might perhaps be compared with the clinical improvement as measured, for example, by visual acuity. Should this occur, a useful biochemical method might emerge of studying the development and treatment of this disease.

The action of the vitamin may be better understood if it be pictured as existing in the body largely in the form of hydroxocobalamin, which can absorb cyanide very readily to form cyanocobalamin. The latter could then take part in essential metabolic processes involving the use of cyanide as a brake on respiratory enzymes such as cytochrome oxidase. Based on these theories, a hypothesis[8] has been put forward regarding a possible role of vitamin B_{12} in human nutrition, involving its participation in the synthesis of methionine. This is one of the sulphur-containing aminoacids in the lens of the eye in which main interest has long been centred.[9] In the metabolism of the lens cytochrome oxidase, which plays an important part, is inhibited by cyanide, which may function as a necessary brake on the activity of the enzyme and thus be indeed an essential metabolite. The rate of excretion of minute traces of cyanide in the breath of normal subjects has been found to be related to the basal metabolism, indicating that the cyanide is taking part in general metabolic processes.[10]

These theoretical aspects may provide a basis for the practical treatment or prevention of tobacco amblyopia by administration of vitamin B_{12}, preferably orally, in frequent small doses, supplemented perhaps with thiamine and other B vitamins. Study of the cyanide-thiocyanate metabolism (e.g., by estimation of serum-thiocyanate or of urinary thiocyanate excretion) might be helpful.

King's Langley, Herts. **FRANK WOKES.**

SIR,—I was very interested in the article by Dr. Heaton and his colleagues. I should like to comment on the suggestion that the nutritional retrobulbar neuritis of prisoners of war may be due to a combined deficiency of vitamins B_1 and B_{12}.

In West Africa, some of my most extended trials were done with autoclaved 'Marmite'. This was a follow-up of the work of Landor and Pallister[11] at Changi Civil Prison, Malaya, who had demonstrated that autoclaved marmite would cure the skin lesions of what is recognised today as "ariboflavinosis", as would ordinary marmite, which I had been using. There was also strong presumptive evidence of a similar effect on vision.

While autoclaved marmite produced dramatic cures of the more visible lesions, including keratitis, confirmative evidence about neurological lesions required months of observation and careful selection of cases. Only those with a very recent history of nutritional retrobulbar neuritis could be selected, for within a few months irreversible changes would occur and a known effective treatment could not be long withheld. I found nutritional retrobulbar neuritis responded as well to autoclaved marmite as ordinary marmite.

Beriberi was a rare disease in Southern Nigeria where the staple carbohydrates were different from the Far East, and rice a "luxury". I saw no evidence of it, clinically, in any patient.

The discovery of ariboflavinosis cleared any doubts about the oral and skin lesions, formerly held to be "pellagrous" (though by 1938 nicotinic acid had been virtually excluded). But any coexistent neurological condition remained obscure. My own belief is that marmite contains that "something else", still unknown, which is both a protective and curative factor. Against riboflavine affecting neurological conditions is the absence of experimental proof. As long ago as 1940 V. P. Sydenstricker told me that neither he nor his colleagues had been able to find any evidence of retrobulbar neuritis in their cases of ariboflavinosis.

Vitamin B_{12} has always offered a possible link-up with these problems and has been a logical consideration for follow-up ever since its discovery. So far as I know the only such trial has been that of J. H. Walters in Arabia. In a personal communication (1953) he informed me of its success in cases of recent origin of a nutritional ataxic syndrome. This condition however, appeared to be separate from nutritional retrobulbar neuritis as in none of his cases was there any evidence of this.

It may well be there is more than one type of dietetically produced "cord" syndrome. Pallister[12] described an ataxic paraplegia in Chinese Malays which was not associated with a retrobulbar neuritis.

Finally, almost all P.O.W./F.E. medical officers state that nutritional retrobulbar neuritis is not caused by vitamin B_1 deficiency. Denny-Brown[13] and Spillane,[14] both of whom conducted exhaustive surveys of nutritional neurological conditions in Service personnel, said the same.

Nutritional retrobulbar neuritis is a true deficiency disease. While much can be definitely excluded, its exact cause remains unknown.

LECTURES ON TAPE

SIR,—We read with interest Dr. Oakley's letter (Aug. 23) in which he mentions our suggestions for a library of medical tape-recordings. He, and others, may like to know that, although our original ideas have been greatly modified, they have developed into the Medical Recording Service of the College of General Practitioners, which has for some months now been issuing talks on tape and long-play gramophone records to members of the College.

TREATMENT OF NEPHROTIC SYNDROME WITH CHLOROQUINE

SIR,—The usefulness of adrenal corticoid therapy in treatment of the nephrotic syndrome is well documented and has been recently reviewed.[15] Dr. M. Plaza de los Reyes (July 19) reports good results following the administration of 0·75 to 1·0 g. chloroquine diphosphate for 2 to 4 months to three patients with "the nephrotic type of chronic nephritis". Our own experience with chloroquine therapy in three adults and four children with idiopathic nephrotic syndrome has been disappointing.

The children received at least 0·25 g. and the adults 0·75 g. chloroquine diphosphate for 2–3 weeks. The hydroxy-ethyl amino analogue of chloroquine was administered to two children. A complete remission occurred in one child and proteinuria decreased in two adults. However, no improvement occurred in the other four patients, although subsequent corticoid therapy produced complete remission (disappearance of proteinuria) in all of them. Thus, in our experience with somewhat smaller dosage and shorter courses than those employed by Dr. Plaza de los Reyes, chloroquine therapy has been far less effective than corticoid therapy in the treatment of idiopathic nephrotic syndrome.

"LIVER FUNCTION"

SIR,—The references in your leader of Aug 23 to fractional determination of bilirubin pigments may be regarded as misleading, even when allowance is made for brevity

Firstly, it is not clear whether by fractional determinations is meant chromatographic separation by one of the methods of Lathe and his coworkers, or the more familiar one-minute and total bilirubin levels which have been advocated by Watson and others [1,2] In either case the implication that the method has yet to be used as a test of liver function is misleading Results obtained with the chromatographic method in the differential diagnosis of regurgitation jaundice [3,4] have been disappointing since there is considerable overlap in the patterns found in hepatitis, in extrahepatic biliary obstruction, and in jaundice due to malignant metastases Neither of the reported studies can be regarded as exhaustive, yet it is my opinion that in the differential diagnosis of jaundice chromatographic separation of the serum bile pigments gives no useful information that cannot be obtained more simply by a total bilirubin estimation with specific attention to the type of van den Bergh reaction, and the performance of a simple but sensitive test for bilirubin pigments in urine Your more optimistic attitude may be justified if a method can be found to separate and estimate the bilirubin pigments without preliminary precipitation of the plasma-proteins

It is wrong to suggest that fractional determination of bilirubin pigments is a necessary investigation in the differentiation of the two rare conditions known as the Dubin-Johnson syndrome [5,6] and Gilbert's disease In Gilbert's disease the van den Bergh reaction is negative and bilirubinuria absent in the Dubin-Johnson syndrome the reaction is positive and bilirubinuria is usual More complex methods give results in accord with these simpler observations but are no more certain Where the total concentration of bilirubin pigments is less than 3 mg per 100 ml, as it commonly is in these two conditions, chromatographic separation may be impossible or inaccurate

HAZARDS OF CHLOROTHIAZIDE THERAPY

SIR,—The warning of Professor Rosenheim and Dr Ross (July 26) is timely Apart from the cases they mention there is another group of patients who may respond well to the drug but in whom unexpected hazards may arise as a result of its use I refer to those patients with hepatic cirrhosis with ascites and œdema who may have a most satisfactory diuresis on chlorothiazide with initial relief of symptoms In these cases the danger appears to be that hypokalæmia may occur and precipitate the onset of hepatic failure and even hepatic coma, as occurred in a case I observed

A man of 62, who was known to have had cirrhosis of the liver for several years, was admitted with ascites and gross œdema There was considerable diuresis on chlorothiazide therapy which was measured by a fall in weight from 238 lb to 219 lb in ten days After this the patient felt greatly improved, but fourteen days after admission he became restless, tremulous, and confused and obviously on the verge of hepatic coma into which he passed in twelve hours At the time these symptoms began the serum-potassium was 4 5 mEq per litre, but even after the chlorothiazide had been withdrawn the level continued to fall, the lowest figure being 2 9 mEq Intravenous therapy with 20% glucose solution and added potassium chloride resulted in his recovering consciousness although he unfortunately relapsed two weeks later and died

The only obvious precipitating cause of the hepatic coma was the lowered serum-potassium level, so that in cases such as this it seems as important to combin potassium chloride therapy as in cases of cardiac œdem treated with this diuretic

JOHN LISTER

INDUSTRIAL MEDICINE AND GENERAL PRACTICE

SIR,—In a leading article in *The Times* of Aug 4, the contention of Dr Stephen Taylor (now Lor Taylor) that "a large part of Industrial Medicine i neither more nor less than General Practice " i quoted, with approval, and on this basis a case is built up for the development of industrial medicine along thes lines Of course, Lord Taylor is entitled to his opinion but as is well known this was not the view expressed in the report of the Committee of Enquiry on Industrial Health Services (the Dale Committee) The true function of industrial medicine, of course, is to advise management, and to suggest that it is just a form of general practice can only do harm by misleading both physicians and industrialists The fact is that there is really no place at all within the factory for general practice, which should be undertaken by the proper person, who is the family physician, any other arrangement will only undermine his authority to the patient's disadvantage In any case, the industrial physician should have something better to do than to seek to duplicate facilities already available through the National Health Service This is not to say that the family physician has no part to play in an industrial medical service, but it is not that of general practice

VAGOTOMY IN HYPERTROPHIC PULMONARY OSTEOARTHROPATHY ASSOCIATED WITH BRONCHIAL CARCINOMA

SIR,—Mr Huckstep and Dr Bodkin, in their interesting article of Aug 16, report regression of bilateral gynæcomastia after vagotomy in a case of inoperable bronchial carcinoma I would like to record a similar experience

A man, aged 70, was admitted in April, 1958, to Baguley Hospital with carcinoma in the left upper lobe, clubbing of fingers and toes, osteoarthropathy with mild symptoms, and bilateral gynæcomastia which had been present for five months Both breasts were enlarged, firm, pyriform, and slightly tender

A left thoracotomy was carried out by Mr John Dark on May 7 The tumour was found to be extensively invading the chest wall, as a result of this and other considerations it was not possible to remove the tumour The left vagal trunk, below the recurrent laryngeal branch, and the pulmonary branches were divided Biopsy of the left breast was performed The report (Dr T A White) is as follows

"The fibro-fatty tissue contains an abnormal number of breast ductules surrounded by loose periductal stroma which is infiltrated by chronic inflammatory cells Some of the ducts are dilated, many show marked epitheliosis, some papillary outgrowths are present in the lumina, and some ducts are almost filled by hyperplastic epithelium No mitoses are seen in the sections, there is no evidence of extraductal invasion or of carcinoma The appearances are consistent with a diagnosis of gynæcomastia"

Following operation, the gynæcomastia gradually regressed The patient was seen again on Aug 22 Although his condition

LESLIE DOYLE

PLEURAL BIOPSY

SIR,—In your annotation of Aug 23 you mention two American reports on the value of this procedure, based on series of 23 and 31 cases Perhaps you will allow me a little space to give a brief outline of the findings of Dr A C Pollard, Dr M J Purves, and myself Our results will be fully reported in two papers submitted for publication several months ago

We have carried out needle biopsy of the pleura in 200 patients, 152 of whom had a pleural effusion of unknown origin In these 152 cases, biopsy gave the diagnosis in 101 cases 70 were tuberculous and 12 malignant, and 10 were due to acute pyogenic infection only The series contained at most 85 tuberculous pleural effusions 70 were diagnosed on the histological appearances of the biopsy specimen and 3 on the results of pleural-fluid culture, while in 12 cases the diagnosis remained a presumptive one only Of the 70 cases with a positive tuberculous biopsy, confirmation was obtained by a positive pleural-fluid culture in 25

It is clear that pleural biopsy is by far the most reliable diagnostic measure in suspected tuberculous effusions, and is very worth while in all other pleural effusions whose cause is not obvious We estimate that blind needle biopsy can be expected to give the diagnosis in 80% of primary tuberculous pleural effusions, and in more than 60% of malignant effusions Where a strong clinical suspicion of primary tuberculous effusion exists, and needle biopsy is negative, full surgical biopsy of the pleura should be done, a patient should not be condemned to a long course of chemotherapy on presumptive evidence alone, for there can be no doubt that in a number of cases such evidence misleads

Churchill Hospital, Oxford

PAUL MESTITZ

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—I have been following with considerable interest the correspondence on this subject It appears that your correspondents are making an initial assumption open to serious doubt This assumption is that the pain of "lumbago" is due to some change in the actual disc itself Mr Charnley (July 5) put the problem in a nutshell "One of the most surprising things about acute lumbago is that the amount of pain does not seem to be proportional to the amount of organic change visible in the disc", and, later in his letter, "we rarely found convincing protrusions in these cases but what is cogent to the present argument is that the material removed appeared more often to be normal than fibrous and stringy"

The argument about hyperhydration or desiccation as the cause of disc protrusion seems largely to be influenced by the theory that it is a rise in intra-disc tension that causes acute lumbago I submit that there is far too little foundation for this assumption Kellgren[1] and Whitty and Willison[2] have shown that pain of a variety of types can be produced reflexly from the muscles (or, as Sinclair et al[3] prefer, the nerves within the muscles) of the back Is it not time that we investigate more carefully the part played by other parts of the invertebral joint in the production of symptoms such as acute lumbago?

HOOKWORM AND ANÆMIA

SIR,—We have read with great interest the recent correspondence on this subject

We do not suppose that there is any dispute that a sufficiently large hookworm load will cause anæmia

Dr Tasker's figures[1] suggest that a relatively moderate load of 800 worms may cause a daily loss of 80 ml of blood We have frequently counted 1000–3000 worms in the stools after giving a vermifuge Hookworm infection is so widespread in Africa that, although probably only a small proportion of those infected carry a sufficient load of worms to cause clinical anæmia, this small proportion is in absolute numbers so large as to constitute, in many places, a serious medical problem

We have recently carried out some observations which show that heavy, but not light, hookworm loads cause a demonstrable fall in the absorption of nitrogen from the intestine Ventkatachalam and Patwardhan[2] have shown that ascaris can behave similarly, and Stewart[3] showed that *Hæmonchus contortus* diminished nitrogen absorption in the sheep Various authors have claimed that ascaris secretes an antiproteolytic substance into the intestine, and Stewart has claimed that *H contortus* does this in the sheep So far as we are aware, the question of the production of an antiproteolytic substance by hookworms has not yet been investigated

Apart from any effect of parasites, there is evidence that a diet low in protein by itself decreases nitrogen absorption[4–6]

May not the sequence of events be somewhat as follows? In a population exposed to hookworm infection, those on a diet poor in protein secrete a diminished amount of proteolytic enzymes in the intestine Hookworms, on reaching the gut, thus find it relatively easy to establish themselves They produce their antiproteolytic substance, still further damaging the host's power of absorbing nitrogen, and therefore his power to secrete digestive enzymes, so setting up a vicious circle Presumably the diminution of proteolytic enzymes will encourage the lodgment of fresh worms Conceivably protein depletion may also hamper the host's resistance to invasion by the infective larvæ Removal of the worms with the administration of iron will cure the anæmia—until reinfection occurs

Such a hypothesis would help to explain the observation that in some communities the percentage of persons harbouring hookworms is very high, but heavy loads and gross anæmia are rarely seen, and that those with heavy worm loads and gross anæmia so often give a history of having lived on a diet greatly deficient in protein

East African Medical Survey and
Research Institute,
Mwanza, Tanganyika

E G HOLMES
S J DARKE

SIR,—We have estimated the blood and iron losses in the stools of anæmic and non-anæmic patients with heavy, light, and no hookworm infection This has been done over periods of 40 to 50 days before giving a vermifuge and for 10 to 30 days afterwards

The blood and iron content of the stools were estimated using ^{59}Fe ($FeCl_3$) and ^{51}Cr (Na_2CrO_4) by the recognised techniques modified to meet our special requirements 10–15µc of ^{59}Fe and 100 μc of ^{51}Cr were given intravenously either as ferrated plasma or chromated cells and thereafter the whole stool collected daily The radioactivity was measured on each stool separately using a ring of six 10-inch halogen-quenched Geiger-Muller tubes The stools were then dried and powdered and re-read in the counter, as well as in a plastic wrap-round pot in a scintillation counter, using a thallium-activated sodium-iodide crystal Plasma-volumes, red-cell mass, and iron clearances and utilisation were determined and the expected pattern for hypochromic anæmias found

---

[6] Pellet, P L *Proc Nutr Soc.* 1957, 16, x.

The following data refer to an anæmic adult male African patient with many hookworm eggs in the stool who entered hospital on May 23, 1958 Hæmoglobin (Hb) 3 7 g per 100 ml, mean corpuscular Hb concentration 25%, packed-cell volume 14%, a very active erythronormoblastic sternal marrow Free HCl in gastric juice Given 1 0 g (gr 15) of ferrous sulphate daily from May 29 to July 30 Hookworms still present but Hb rose to 14 6 g per 100 ml on July 8 Blood and iron *losses during the 39 days before worming totalled 470 ml* and 171 mg respectively (mean daily loss 12 ml and 4 4 mg)

Daily losses of blood were extremely variable (1 6 ml – 25 0 ml) emphasising the desirability of daily measurements As was to be expected, the iron losses increased as the Hb level rose, so that a similar blood loss will result in a greater iron loss in less anæmic patients

On July 8 the patient was given a vermifuge of tetrachlorethylene followed 3 hours later by a magnesium-sulphate purge 1100 *Necator americana*, 2 *Tænia saginata*, and a few ascaris were recovered from the stools passed during the next 48 hours A second vermifuge was given on July 25, but no hookworms or other parasites were recovered

The blood and iron losses were similarly estimated for 13 days after the vermifuge, and gave a total blood-loss of 24 ml and an iron loss of 12 mg with mean daily values of 1 8 ml and 0 9 mg

Since there are considerable intestinal mucosal losses (30–80 g daily) some part of the fæcal iron may have come from this source, in patients with heavy worm loads mucosal desquamation rates may be higher than in non-infected patients

The amount of radioactivity found in the hookworms was *equivalent to approximately 0 002 ml* blood per worm (=0 005 mg Fe) We do not regard this figure as in any way significant, since it is not the amount of blood that the worms consume that is important but their migratory browsing habits which may leave bleeding points in the mucosa and the possibility that they may " pump " blood through them in the act of sucking

Taking into consideration the variations in the hæmoglobin level during the whole period of observation before de-worming, 9 0 mg of Fe were lost in the first 13 stools passed after the dose of ^{59}Fe with a mean hæmoglobin during this period of 4 g per 100 ml, in the following 13 stools taken during the period when the average hæmoglobin was 7 g per 100 ml 18 mg of iron were lost, in the next 13 stools taken during the period when the hæmoglobin was 12 g per 100 ml, 74 mg of Fe were lost, and in the final 11 stools collected when the hæmoglobin was 15 g per 100 ml, 70 mg were lost Thus during the 39 days prior to the removal of the 1100 hookworms, 171 mg of iron were lost—a daily average of 4 4 mg In spite of heavy hookworm loads only on two occasions did the daily loss of blood exceed 20 ml (25 ml and 23 ml) and this when the hæmoglobin level was 4 0 g per 100 ml, thus giving an iron loss on these two days of only 2 5 and 2 0 mg

In the 13 days following the removal of the worms the patient lost 24 ml of blood and 12 mg of Fe, taken at a 15 g per 100 ml hæmoglobin He was discharged from hospital on July 26 with a hæmoglobin of 15 0 g per 100 ml

From the above facts it seems that

(1) Normal *hæmoglobin levels can be attained in very* severe iron-deficient anæmia by giving oral iron therapy alone while leaving the worms in situ even in cases such as the above that *have heavy hookworm loads*

(2) There are wide daily variations in the amount of blood and iron lost

(3) Heavy hookworm loads do not always produce significant blood and iron losses, and that there is not always a correlation between worm loads and blood-loss This blood-loss can be diminished by either iron treatment or transfusions, while leaving the worms in situ, indicating that worms are not the only factor involved[1,2]

(4) Iron losses, although diminished, may continue after the removal of the worms, perhaps owing to the temporary persistence of bleeding points in the gut

(5) *Similar blood-losses give rise to higher iron losses* as the hæmoglobin of the patient rises, a point not always appreciated

(6) Some of the iron liberated from the blood in the gut may be reabsorbed, although hæmoglobin is not a good course of iron

(7) *Intestinal cellular desquamation* may be high in parasite-infected patients and may account for some of the iron lost

It should not be concluded from this example that all patients having hookworms are anæmic or that all patients with iron-deficient anæmias in the tropics have hookworm

Full details of this work will be published elsewhere with the findings in anæmia without hookworms and in non-anæmic patients with hookworms

NEUROTROPIC VIRUS IN AFRICAN MONKEYS

SIR,—In view of the increasing use of African monkeys for tissue-culture purposes, we wish to record that a virus resembling the B virus of Sabin and Wright[3] has been isolated twice in these laboratories from central-nervous-system tissues of the African vervet monkey *Cercopithecus æthiops pygerythrus*

This virus produces nuclear inclusions and small syncytia in cultures of monkey-kidney epithelium The intradermal and subcutaneous inoculation of rabbits is followed by marked necrosis of the skin and, in some instances, by paralysis and death, and the virus has been recovered from the brains and spinal cords of rabbits showing paralysis Neutralisation tests with anti-B virus *sera indicate that there is a serological relationship between* B virus and the agent we have recovered, which we have designated SA8 in the series already described by us[4]

UNSATURATED FATS AND IMPORT RESTRICTIONS

SIR,—Dr Bourdillon (Aug 23) is incorrect in stating that patients in Britain are unable to purchase corn oil Maize oil (corn oil) *B P C* is freely available for purchase by patients at retail chemists in the United Kingdom A simple, palatable emulsion containing approximately 50% of maize oil *B P C* can also be obtained by those who dislike the taste of pure maize oil

Both preparations are being prescribed A number of long-term clinical studies are also being *carried* out at different centres in view of the observation that the ingestion of certain vegetable oils will result in the lowering of a raised serum-cholesterol Published work suggests that maize or corn oil, given in adequate quantity, is probably *the most active* of these vegetable oils in its cholesterol-lowering property

HOW TO BE HAPPY THOUGH RESIDENT

SIR,—I wish I had been able to read Mr Bryan Jennett's article, in your last issue, five years ago when I first qualified I am sure it will save all new housemen who read it from finding out many things the hard way when they start in hospital

Putting yourself in the other person's position, writing down things clearly in case-notes, and dealing with the proper people are but three pieces of advice which in retrospect are invaluable

Liverpool C R PORTEOUS

Public Health

Influenza this Winter

MEETING in Stockholm recently with Dr C H Andrewes as chairman, the World Health Organisation's expert committee on respiratory virus diseases said that the A/Asia/57 virus is likely to be the predominant type in influenza outbreaks during the next few years People infected during the pandemic of 1957 are likely to have at least a basic immunity

Large quantities of vaccine, providing 60–70% protection, are now available in several countries From a clinical standpoint, its use is especially important for expectant mothers and people suffering from cardiovascular or lung disease, or metabolic disorders To offer maximum protection, it should be given at least a fortnight before influenza is expected to become epidemic There can be no question of stopping an epidemic by vaccination what is aimed at is limitation of its effects by preventing high death-rates and excessive absenteeism, such as might disorganise public services

Vice-chairman of the committee is Prof V M Zhdanov, of Moscow, and, among other advances in vaccine research, work in the U S S.R with attenuated live virus vaccines was reviewed Unlike the formalin-inactivated influenza virus, the live vaccine is not administered by inoculation but sprayed into the nose and throat Because of its high virulence, it is not recommended for children under 7 years old

Mention was made of a method—promising but unproven—by which stocks of vaccine may be made to go further by mixing with an "adjuvant" The possibility of an animal reservoir of human influenza was also discussed Several studies of this, initiated by W H O, are in progress

Carbon Dioxide in Harvested Grain

The Ministry of Agriculture, Fisheries, and Food has pointed out that grain harvested wet may give off carbon dioxide This can happen in any place where grain is stored, and the gas, being heavier than air, will collect in the pits or ducts of a grain-handling plant When carbon dioxide is detected by the extinction of a lighted match or candle, the place must be thoroughly ventilated Anyone working in these places who feels faint or dizzy should get out at once

Preservation of Citrus Fruits

The Minister of Agriculture, Fisheries, and Food and the Minister of Health, acting jointly, have made the Public Health (Preservatives, &c, in Food) (Amendment) Regulations, 1958, which permit the importation and sale of citrus fruit containing diphenyl or ortho-phenylphenol or admixtures of the two substances within prescribed limits

Obituary

CHARLES CADY UNGLEY

M.D Durh, F R C.P

Dr Ungley, who died at the age of 55 in the Royal Victoria Infirmary, Newcastle upon Tyne, on Aug 21, was a general physician, skilled especially in hæmatology and neurology, who in the midst of general hospital duties, teaching, and (for many years) private practice maintained a passionate interest and immense industry in research

He qualified in Newcastle in 1925, and, after a trip to the Far East as a ship's surgeon, he held resident appointments at the Royal Victoria Infirmary, taking his M D in 1927 and his M R C P in 1928 His research ability was soon apparent, and in 1930, with a Rockefeller studentship, he visited America, working at Harvard University and at the Massachusetts General Hospital He was appointed to the staff of the Royal Victoria Infirmary in 1933 and in 1935 was awarded a Leverhulme scholarship of the Royal College of Physicians to study pernicious anæmia In 1937 he was elected F R C.P, and in the following year he gave the Goulstonian lectures, on deficiencies of nutrition and their relation to disease

His chief interest was in pernicious anæmia and he developed fundamental techniques for the clinical assay of liver fractions As a by-product of this work he provided the Royal Victoria Infirmary with a first-class hæmatology service During the late war he served with the Navy, and his work on survival at sea was, and remains, of the highest importance It was based on immense labour in the collection of data, and included his special study of immersion foot But after the war he returned to pernicious anæmia and was at hand with a fully developed organisation for the first clinical trials of vitamin B_{12} His work on the comparison of vitamin B_{12} and liver extract in the treatment of subacute degeneration was an outstanding example of the careful elicitation of neurological signs and their expression in quantitative terms At the end of his life he was trying to extend this work using serial psychometric tests to study vitamin-B_{12} deficiency in the brain Of his continuous interest in this research F J N writes

"Charles Ungley was at once fascinated by the report by Minot and Murphy of the efficacy of liver diet in the treatment of pernicious anæmia and was one of the first to demonstrate the remarkable improvement which could often be obtained by early treatment of subacute combined degeneration of the cord with liver One of his earliest papers, published in the *Newcastle Medical Journal* in 1929, was on this subject He continued with this work after the war and the results of his most meticulous studies were published in *Brain* in 1949 The great developments of hæmatology opened up by the discovery of the liver treatment found him in the forefront of clinical and experimental research Under the stimulus of Castle's hypothesis he strove to determine the nature of the extrinsic and intrinsic factors, and, most notably, collaborated with Lester Smith in testing the potency of purified liver extracts and ultimately of vitamin B_{12}"

Ungley was deeply conscious of his responsibilities to his students His firms were always happy ones He enjoyed teaching and was good at it, and those who came to his ward, especially on a Saturday morning, were well rewarded. Himself a specialist of specialists, he was determined that his ward clerks should see medicine in a wider setting, and, long before it became official policy to do so, he used to arrange for them to visit a number of general practitioners during their appointment. Of this scheme A. S. relates:

"Ungley approached four general practitioners (of whom I was one), with urban, semi-urban, rural, and small-town practices, and persuaded each to take a student for one day weekly and show him something of general practice. This scheme differed from most others which have been introduced since, in that the student saw different types of practice and different doctors, and saw them at the beginning of his hospital career. This made him realise that patients are people with homes and families, not merely vehicles of disease, and coloured his later dealings with patients in hospital."

The affection, as well as respect, which Ungley inspired is shown by R. E. I.'s words about his old chief:

"Charlie's figure was slight and athletic, his manner diffident, and he always looked a little windswept (he loved to drive an open car). Any conversation was punctuated by the frequent lifting of his eyebrow to a fascinating height. His later years were dogged by illness, but he never allowed this to diminish his appetite for life. A few years ago he took up gliding, and his pleasure was infectious when he passed the tests that entitled him to fly solo. When ill health put an end to flying he took up art, and in the last year of his life achieved some notable oils. Despite his world-wide reputation he remained the most modest, lovable, and approachable of men, and he always retained something of the simplicity of childhood. He was sometimes shy with adults but he was always at home with children and they loved him. No-one who saw him dancing with a little girl who came downstairs in her nightgown in the middle of a party, or who watched him cooking sausages at a family picnic, could doubt that, stricken though he was in health, he would never lose the secret of youth. To work with him was to receive a priceless education in clinical investigation; it was also to have contact with a human spirit of the rarest quality."

Dr. Ungley leaves a widow, a son, and two daughters.

HUGH ARTHUR SANDIFORD

M.C., M.B. Manc., D.P.H.

As the first director of Army psychiatry and again as the first director of the Commonwealth and the International Advisory Bureaus of the British Medical Association, Brigadier Sandiford proved his worth as a pioneer medical administrator.

He was born at Manchester in 1892 and educated at the grammar school and university of that city, qualifying in 1914. Almost at once he joined the R.A.M.C., and in 1917 he was awarded the M.C. for gallantry while looking after casualties under heavy artillery fire. After the war he decided to remain with the R.A.M.C., and in the next years he gained valuable experience both of clinical medicine and of administration. In 1925 he took the D.P.H. and in 1933 he was appointed instructor at the Army School of Hygiene. Later he became assistant director of hygiene at the War Office and deputy director of hygiene in Eastern Command.

At the beginning of the late war his wide experience of physical assessment persuaded him of the importance of devising suitable methods of selection, and his interest in this task led in due course to his appointment as director of Army psychiatry at the War Office. His success in what was not an easy assignment was appreciated by his psychiatric colleagues, one of whom, T. F. R., writes:

"It is no secret that the rise of psychiatry during the early years of the war was viewed with disquiet by many senior members of the Army Medical Services. When it became necessary nevertheless to provide adequate administrative arrangements for these developments, it was a relief to many to know that a Regular as wise and as moderate as Sandiford had been appointed director of Army psychiatry. To our surprise we psychiatrists quickly learned that we had acquired a good friend whose understanding and confidence in the potential value of the contribution we could make to preventive medicine was greater than our own. He may have exerted a steadying influence upon us, but—what was far more important—he inspired us to work in new directions. His own World War I experience led him to take a special interest in the problems of repatriated prisoners of war and, as a result, psychological studies were made which resulted in the setting up of civil resettlement units towards the end of the war. The experience thus gained has led to many other experiments in rehabilitation of a similar kind and to the setting up of other therapeutic communities, but the first insight which led to these experiments in social psychiatry we owe to Sandy. He was a quiet man whose sincerity and integrity showed itself in all his actions, and he very easily won the trust and affection of all who worked with him."

During his years in the Army he had met and worked with medical officers from many parts of the world, and especially of course from the British Commonwealth. When, in 1947, shortly after he retired from the Army, the B.M.A. decided to set up their advisory bureaus to help medical visitors from abroad, Sandiford was chosen, from over a hundred applicants, as director of the new venture. His talents for kindliness and organisation complemented each other, and he offered those who came to the bureaus a friendly welcome backed by useful information and practical advice. Of this second stage of his career a colleague writes:

"Sandiford was well suited for his work at the B.M.A. He was shrewd and often blunt, but he was above all a kindly man, interested in human affairs. His work bore the mark of the skilled administrator, but, unlike many administrators, he was capable of the liveliest initiative when need arose. The need did arise when Hungarian doctors began to arrive in this country as refugees in the autumn of 1956. Of the two score or so who reached here, nearly all soon found their way to Sandiford's office. No matter what their needs—a passage to South America, thirty shillings for a train fare, accommodation in Scarborough, a new suit, news of relatives in Budapest, a job in Bristol—Sandiford did his best, and, because (despite his genial air) he did not shrink from ruthless unorthodoxy, he usually succeeded. The ripples of the Hungarian revolution have died away, but it is certain that the doctors who then came to England will not forget Sandiford—equable, courteous, benign, and wise, always ready to listen and to act."

Brigadier Sandiford retired from his work with the B.M.A. last year and he died on Aug. 13 at his house in Windsor. He leaves a widow, two daughters, and a son, Dr. R. H. Sandiford.

Dr. J. BROCK BISHOP

P. G. McG. writes:

"Brock Bishop had a tremendous zest for the full life. His interests were wide, and to each one of them—social, professional, and purely recreational—he gave a full measure of his abundant energy. I saw this mainly in his medical work, where his conscientious attention to every facet of the life of his patients not only paid handsome clinical dividends, but earned him the respect and deep affection of patients and colleagues. His devotion to duty did not result in a dreary rigidity, but was clothed in a vivid, flexible human approach, the patients' own attitude and susceptibilities would extract from Brock the formal courtesy of which he was a master, or through the whole gamut to a friendly raciness of language which on occasion enlivened his reports as well. The memorial which he would appreciate most is the affectionate smile which comes to every face in Broadmoor at mention of his name."

CHEVALIER JACKSON

M.D. Jefferson, D.Sc. Penn., LL.D. Temple

Chevalier Jackson was born in Pittsburgh in the last year of the American Civil War. As a frail sensitive child he was shocked by the brutal sports and cruelty of the farming and coalmining community in which he grew up, and at school he was exposed to merciless bullying. The misery of these years was mitigated by the happiness of his home where he was encouraged to read, to draw, and above all to make things.

He began to use wood and sharp tools at the age of four and thereafter, he wrote, "I was never without a workshop; later it was called a laboratory, but it was always a place for constructive work." Carpentry was his first manual skill. In the next difficult years he acquired others, and his thrifty genius wasted none. At the family hotel he was put in charge of the uncertain gas-generating plant and water system. To fit himself for this task he served a summer vacation as a plumber's apprentice. His experience with tubes and valves led later to his discovery that in the heart and lungs there are mechanisms parallel to the stop valves, by-pass valves, and check valves of pipes, pumps, and plumbing. "My whole life's work with the air and food passages seems curiously parallel in its fundamentals to those boyhood days as a plumber's cub." To earn money to pay for his first year at college he worked as a china and glass decorator, painting apple blossom and butterflies on lamp shades and stands. Later this talent allowed him to reproduce what he saw for medical illustrations in colour.

His medical training was only accomplished with difficulty. After a year with a "preceptor", Dr. Gilmore Foster, he entered Jefferson College, Philadelphia, in 1884. When his fees had been paid, he was left with 63 cents a day for all his other expenses. In the long vacation he sold medical books on commission, and sailed as ship's cook to the cod-fishing in Newfoundland. The M.D. course in those days was two years, and he graduated in 1886 still six months short of the legal age of twenty-one.

The new graduate had already chosen his specialty. A dispensary for diseases of the ear, nose, and throat had lately been set up in Philadelphia, and as a student he had attended it regularly. His teacher, Dr. J. Solis Cohen, had lent him a complete set of the writings of Morell Mackenzie, and he decided without delay to visit Mackenzie's clinic in London. He accumulated a little money and sailed steerage for Europe and London. He stayed as long as his funds held out, and on his return to Philadelphia boldly set up in consultant practice.

To begin with much of his practice was among the children of the poor. The value of tonsillectomy was becoming more widely recognised, and Chevalier Jackson was so convinced of its merit that he offered to examine and operate on the children in the local schools. In those days, too, stricture of the larynx was often the tragic sequel to diphtheria, and he won a reputation for his skill in treating these children by tracheotomy and by intubation. In nearly every American kitchen lye was used as a cleaning material. It looked like sugar and too often it stood unlabelled, tempting and unguarded. If a child put it in his mouth, the oesophagus was burnt and the contracting scars gradually closed the passage till the child died of starvation. The misery of these small patients led Chevalier Jackson to embark on his long campaign (which only succeeded in 1927) to make it compulsory that preparations containing this dangerous substance should carry a poison label and a warning to keep them out of the reach of children.

In treating these small patients he used an instrument which he had adapted from a device he had first seen in Morell Mackenzie's clinic. In his hands the instrument was improved, a light carrier was added, and it became the oesophagoscope. As well as for lye strictures he used it for the removal of foreign bodies. For his diphtheria patients he was already using a laryngoscope, and his skill and success with these instruments led him to the study of bronchoscopy. His belief in the value of these new techniques forced him into the role of teacher and soon he was giving bronchoscopic courses in Pittsburgh, Philadelphia, and Paris.

In 1911 his work was restricted, though not interrupted, by his first attack of tuberculosis. He was ordered to supplement his austere diet and to spend 12 out of every 24 hours in bed. Though much of his bed rest was spent in annotating his case-records and making sketches of laryngeal and endoscopic views of pathological tissue, his infection was halted and in six months he was back at work. But two years later he had a recurrence, and renewed bed rest was ordered. With some misgivings, for the sake of his health he gave up the most remunerative part of his practice—tonsil and adenoid operations—and henceforth limited his specialty to laryngoscopy, bronchoscopy, oesophagoscopy, and gastroscopy. He also used his enforced rest to write his book on *Peroral Endoscopy and Laryngeal Surgery*, which was published in 1915.

As early as 1900 he had been elected to the chair of laryngology in the Western Pennsylvania Medical College, later the University of Pittsburgh, and with the years his reputation grew steadily. In 1915 the New York Post-graduate Medical School appointed him professor of bronchoscopy and entrusted him with the organization of a new department of bronchoscopy, but he had only held this chair a short time when his third attack of tuberculosis forced him to resign. Despite his uncertain health, in 1916 he made the decision to "pull up stakes" and move from Pittsburgh to Philadelphia, where he had been offered the chair of laryngology at Jefferson College. Academic posts then offered prestige and opportunity but no salary, and the move meant giving up a private practice which was just beginning to be lucrative to start again from the beginning. But his welcome from his colleagues in Philadelphia heartened him, and three years later the University of Pennsylvania created for him a chair of bronchoscopy and oesophagoscopy, and in 1924 Jefferson College followed their example. To this formidable array of chairs, almost all specially endowed for him, he later added chairs at Temple University and at the Women's Medical College of Pennsylvania (of which he was also president).

He accepted his responsibility as one of the founders of a new specialty and travelled all over the world to give lectures, attend conferences, and share in discussions.

Many of his colleagues in this country will still recall his address to the British Medical Association at Bath in 1925. One of them later wrote[1]: "The slight puckish figure, clothes loosely fitting and collar two sizes too large . . . with a rubber manikin and gleaming instruments, drawing chalk diagrams with both hands, showing more and more lantern slides and short cinema films, and talking and talking with enthusiasm, straight on for two hours " On many of his journeys he received professional, academic, and national honours His appointment as officer of the Legion of Honour of France was particularly appropriate, for he was linked to that country by ties of kinship

---

[1] Scott Stevenson, R. In a Harley Street Mirror, p 140 London, 1951

In his private life, too, Chevalier Jackson was always aware of his specialty His simple and austere life may not have been uncongenial, but abstinence from tobacco and alcohol, his abstemious, vegetarian meals, his habit of wearing gloves, all safeguarded the dexterity of his sensitive fingers and the steadiness of his eyes and nerves

Soon after he came to Philadelphia he and his wife settled in an old grist and saw mill about 35 miles from the city With characteristic ingenuity the grist mill was repaired and induced once more to earn its keep and to provide the house with electricity In this family retreat Chevalier Jackson was able politely to evade unwelcome social engagements (and nearly all social engagements were unwelcome) and to spend his time in his workshop, writing in a boat on the mill stream, and reading or painting at his study window where he shared the sill with rabbits, quails, and birds

He died on Aug 16 in the hospital of Temple University, Philadelphia, where his son, Dr Chevalier L Jackson, is now professor of laryngology and broncho-œsophagology

One of his British colleagues, V N , writes

" The death of Chevalier Jackson marks the end of an epoch in advancement of the knowledge and treatment of diseases of the lungs and œsophagus He added very greatly to methods which not only allowed of instrumentation within the air and food passages but also carried forward investigations into the physiology and pathology of these regions His early days were ones of struggle and of financial difficulty, with tenacity of purpose he concentrated his energies on endoscopic methods in the trachea, bronchi, and œsophagus, though he had difficulty in convincing the medical profession of the importance of this approach

" Of the many distinctions, both in America and in other parts of the world, which came to him, the most important included his election as honorary fellow of the Royal Society of Medicine of London, of the Scottish Society of Otology and Laryngology, and of the Royal College of Surgeons of Edinburgh, and as laureat of the Académie de Medecine of Paris Perhaps one of his most illuminating honours was the conferring on him in 1952 of the Medallion of the American College of Chest Physicians, which emphasises the recognition by the medical profession of his extremely valuable contributions to the field of the chest physician and thoracic surgeon His memory will be treasured by innumerable friends and students who for long have recognised the value of his pioneer work "

Our photograph is of a bust by Luigi Maraffi, presented to Chevalier Jackson by a group of his pupils and colleagues in 1937

Appointments

BRADSHAW, D B , M B Dubl , D P H M O H and principal school M O , Leeds

CAMPBELL, R J C , M B Edin , D M R consultant radiologist, Stracathro Hospital, Brechin, Brechin Infirmary, Arbroath Infirmary, and other Angus area hospitals

CECIL, J T , M B Lond D P H assistant M O , Maidstone area, Kent

GRIFFITH EIRWEN, M B Lond assistant M O , Medway towns area, Kent

MANGAN, GEORGE, M R C S D O ophthalmologist, Ongar, Epping, and Waltham Abbey refraction clinics

MORRIS, P A L A H Dubl , D P M senior assistant psychiatrist, Kingsway Hospital, Derby

SMITH, D ROBERTSON, M D Cantab consultant pathologist, Reading area pathology service

SUMMERS, HARRY, M B Manc , M SC Brist assistant M O , Mid-Cheshire area

Notes and News

APPROVED NAMES FOR DRUGS

THE British Pharmacopœia Commission has issued th following new supplementary list of approved names

Approved Name	*Other Names*
Ambazone	1 4-Benzoquinone amidinohydrazine thio semicarbazone hydrate Iversal
Beclamide	*N*-Benzyl-β-chloropropionamide Nydrane
Benztropine	3-Diphenylmethoxytropane Cogentin is the methanesulphonate
Bisacodyl	Di-(*p*-acetoxyphenyl)-2-pyridylmethane Dulcolax
Chlorphenesin	3*p*-Chlorophenoxypropane-1 2 diol
Clemizole	1-*p*-Chlorobenzyl-2-pyrrolidinomethyl-benzimidazole Allercur is the hydrochloride
Clemizole Penicillin	Benzylpenicillin combined with 1-*p*-chlorobenzyl-2-pyrrolidinomethyl-benzimidazole Megacillin, Neopenyl
Deanol	2-Dimethylaminoethanol *Atrol is the bitartrate*
Dimethisterone	6α 21-Dimethylethisterone Secrosteron
Ethoheptazine	Ethyl (±)-1-methyl-4-phenylazacycloheptane-4-carboxylate Zactane
Framycetin	An antibiotic derived from *Streptomyces decaris* Soframycin is the sulphate
Furazolidone	3-(5-Nitrofurfurylideneamino)oxazolidin 2 one Furoxone
Inproquone	2 5-Bisethyleneimino-3 6-dipropoxy-1 4-benzoquinone
Pempidine	1 2 2 6 6-Pentamethylpiperidine Perolysen is the hydrogen tartrate, Tenormal is the hydrogen tartrate
Phytomenadione	2-Methyl-3-phytyl-1 4-naphthaquinone Vitamin K_1 Konakion, Mephyton
Piprinhydrinate	Diphenylpyraline salt of 8-chlorotheophylline 4-Diphenylmethoxyl-1-methyl-piperidine salt of 8-chlorotheophylline Kolton, Mepedyl
Sulphaethidole	5-*p*-Aminobenzenesulphonamido 2-ethyl-1 3 4-thiadiazole *Sethadil*
Sulphathiourea	*p*-Aminobenzenesulphonylthiourea Badional
Trimethidinium	(+)-3-(3-Dimethylaminopropyl)-1 8 8-trimethyl-3-*azabicyclo* [3 2 1] octane di (methyl methosulphate) Camphidonium

INDEX

Proprietary Name	*Approved Name*
Allercur	Clemizole
Atrol	Deanol
Badional	Sulphathiourea
Camphidonium	Trimethidinium
Cogentin	Benztropine
Dulcolax	Bisacodyl
Furoxone	Furazolidone
Iversal	Ambazone
Kolton	Piprinhydrinate
Konakion	Phytomenadione
Megacillin	Clemizole Penicillin
Mepedyl	Piprinhydrinate
Mephyton	Phytomenadione
Neopenyl	*Clemizole Penicillin*
Nydrane	Beclamide
Perolysen	Pempidine
Secrosteron	Dimethisterone
Sethadil	Sulphaethidole
Soframycin	Framycetin
Tenormal	Pempidine
Vitamin K_1	Phytomenadione
Zactane	Ethoheptazine

INFANTILE DIARRHŒA AND VOMITING IN IRELAND

In the Medical Research Council of Ireland's report for 1957,[1] Dr Owen Conor Ward and Dr Desmond Donovan describe a survey of the incidence and epidemiology of infection by the *Escherichia coli* strains which have been held responsible for communicable diarrhœa and vomiting in infants

The investigation was started on the opening day of a new hospital—Our Lady's Hospital for Sick Children—at Crumlin. For nearly a year rectal swabs were taken on admission and then weekly from infants under the age of two—numbering 647 in all These children were not drawn from one area although most came from Dublin city, many were from country districts

On admission, the rectal swabs of 69 patients were positive for the *Esch coli* variants, of these 62 had diarrhœa or vomiting, or both 329 patients had diarrhœa or vomiting but negative rectal swabs, and in 118 of these no satisfactory explanation of the symptoms was found In general, these were not so ill as the children from whom escherichia strains were recovered only 22 of the 329 were severely dehydrated (and 6 of these had been in contact with pathogenic *Esch coli*) whereas 12 of the 69 swab-positive cases showed such dehydration

All the infants were nursed in separate cubicles by trained staff, yet there was cross-infection with *Esch coli* in at least 31 cases Dr Ward and Dr Donovan conclude, therefore, that dissemination of the infection cannot be prevented by ordinary nursing techniques

MEDICAL SERVICES OF PAPUA AND NEW GUINEA

In our advertisement columns this week the Territory of Papua and New Guinea is advertising the post of assistant director of medical research As local conditions of life and medical practice will be unfamiliar to many of our readers, the Director of Public Health has sent us some notes about them

The combined territories, he points out, include half the mainland of New Guinea and all the islands to the north and north-east Their area is 183,600 square miles and the population 1¾ million, of whom 18,000 are not Papuans Communications by road are limited by mountains and fast-flowing rivers, but air services connect most districts

The people live in villages and hamlets and depend on a subsistence economy, but primary and secondary industries are gradually raising the standard of living The two most important diseases are malaria and tuberculosis Others are filariasis, helminthiasis, amœbic and bacillary dysentery, leprosy, yaws, and venereal diseases, to which may be added such general medical problems as anæmia and pneumonia, with cirrhosis of the liver and kwashiorkor in certain areas

The department of public health, with headquarters at the capital, Port Moresby, provides the curative and preventive services offered by local and central government health authorities in other countries Its doctors also undertake some private practice, and there are other private practitioners in the main centres of Port Moresby, Lae, and Rabaul The department is administered by a director, with assistant directors responsible for divisions of medical services, preventive medicine, medical training, infant child and maternal health, and administration There is a European staff of 80 doctors, 146 medical assistants, 138 trained nurses, and 172 ancillary and clerical staff The indigenous staff consists of 4500 Papuans and New Guineans most of them are semi-skilled orderlies, with a gradually increasing educational level The Christian missions also have a medical staff of 137, of whom 12 are doctors There are 98 hospitals scattered over the entire territory, and 1200 aid posts or dispensaries in the villages

Port Moresby General Hospital, the base hospital for the entire territory, is to be the centre for future medical research It has 370 beds The buildings are of a modern design including air-conditioned laboratories, theatres, and X-ray department The medical staff consists of a medical superintendent, surgeon, anæsthetist, physician, ophthalmologist, pædiatrician, two radiologists, pathologist, chest physician, and 4 resident medical officers The hospital is also a training centre Nurses' training has begun and a medical school is to be opened in 1960 for assistant medical practitioners, along the same lines as the Central Medical School at Suva, Fiji

The aim of the department is to improve the standard of public health in the villages and hamlets, and the emphasis is accordingly being shifted to preventive as opposed to curative medicine But preventive medicine needs basic research into the problems to be controlled, and it is with this need in view that it has been decided to add to the department a division of medical research

In the past, research has been undertaken by isolated individuals, in addition to their normal duties Studies in progress at present include an investigation into kuru, an obscure nervous condition that is almost 100% fatal and probably of hereditary origin Infant and child mortality is also of great local concern.

MEDICAL CERTIFICATES FOR LONG ILLNESSES

The Ministry of Pensions and National Insurance wishes to remind doctors that the Medical Certification Rules allow them, where a patient has been unfit for work for at least 6 months and incapacity is likely to last for some time to come, to give him a single certificate to cover up to 13 weeks ahead even though it may be necessary to see him more often

This arrangement was originally made so as to reduce the amount of routine certification by doctors, and the number of times the patient has to send documents to the local offices of the Ministry It also reduces the routine work in the local offices which has to be done on each claim for benefit When long-term certificates are issued, local offices are able to pay sickness benefit by means of order books covering 8 or 13 weeks, instead of preparing and sending postal drafts week by week. In the last few years the number of prospective certificates issued by doctors has decreased steadily and this has added disproportionately to the work in local offices

Local offices are writing to doctors where they know of cases in which it appears that long-term certificates might be appropriate But it is, of course, entirely at the discretion of the doctor whether he issues long-term certificates or not, and doctors are assured that the Ministry's action is not in any way an attempt to interfere with their discretion

---

University of London

Dr R C Curran, senior lecturer in pathology in the University of Sheffield, has been appointed to the chair of pathology at St Thomas's Hospital Medical School

Dr Curran graduated M B with commendation from the University of Glasgow in 1943 He served with the R A M C and held house-posts at Glasgow Royal Infirmary before he was appointed assistant pathologist and bacteriologist to Stobhill Hospital Before taking up his present post, he was lecturer in pathology in the University of Glasgow In 1956 he was awarded the Bellahouston medal for his M D thesis His published work includes papers on collagen formation in the quartz focus, elaboration of mucopolysaccharides by vascular endothelium, and utilisation of sulphate ion by fibroblasts in quartz focus

Dr M de Burgh Daly, Locke research fellow of the Royal Society in the department of physiology at University College, has been appointed to the chair of physiology at St Bartholomew's Hospital Medical College

Dr de Burgh Daly studied medicine at the University of Cambridge, where he took the natural sciences tripos in 1944, and at St Bartholomew's Hospital After qualifying in 1947, he held a house-appointment at Barts and later became a lecturer in physiology at University College, London In 1952 he was awarded a Rockefeller travelling fellowship and the following year the Schafer prize in physiology He has contributed to Winton and Bayliss's *Human Physiology* and has published papers on innervation of the bronchi and on bronchomotor and pulmonary arterial reflexes

Society of Apothecaries of London

Dr W S C Copeman has been elected master, with Dr R R Trail and Dr Charles White as wardens

The following diplomas have been granted

M.M S A—P R Sathyanadhan
